The three wires chosen for this experiment had diameters 0.0521 cm., 0.0813 cm., and 0.0993 cm., respectively; the first two were german silver and the latter was steel. Each was carefully polished with crocus cloth and chamois skin before being placed in the tube. The wire was carefully placed in the tube and the tension applied for maintaining it straight. The diameter was measured before and after the test. The tube was now exhausted to 10 cm. of mercury absolute pressure and voltage was applied to the wire. If the corona which appeared around the wire was evenly distributed and gave no indications of beads, the wire was ready for observations. It was found advisable to begin at low pressures and gradually increase the pressure by letting air leak in through a needle valve. At low pressures the corona current from the insulated cylinder to the brass tube was very high as compared with the values at higher pressures.

The voltage which gave the first indication of a deflection in the corona indicating circuit was taken as the corona-forming voltage. The magnitude of this deflection, according to Whitehead and Pullen,[8] depended upon the number of ions per second which passed through the holes of the perforated brass

cylinder and gave up their charge to the insulated metal cylinder surrounding the brass one. It was expected and verified experimentally that the current in this indicating circuit was present only if the potential gradient was continued in the same direction as the gradient existing between the inside charged wire and the brass cylinder. A 110-volt storage battery was used to supply this potential gradient, as shown in the diagram of connections. In this battery circuit was connected a D'Arsonval galvanometer of 283-megohm sensitivity to indicate this portion of the corona current.

The polarity of the potential circuit was reversed by reversing the kenotron and the observations were repeated with reversed polarity. When this was done the polarity of the insulated metal cylinder was also reversed.

Each corona indication was repeated three times before a final reading was taken. The pressure, corona voltage, and temperature were observed simultaneously. Curves of voltage and pressure were plotted as the experiment progressed to check any false observation and to insure continuity. The temperature was then changed to another value and the observations repeated. All of the temperature and pressure observations were again repeated for the other wires. No difficulties were encountered with the wire charged positively; however, with the wire charged negatively care was necessary to register the voltage at the beginning of the corona cycle. The general form of the positive and negative corona indicating circuits are shown in Fig. 8.

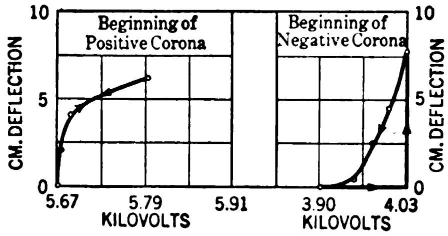

FIG. 8

The difference between these two characteristics was observed by Whitehead[3] and are under further investigation.

RESULTS OF OBSERVATIONS

For the analysis of the results of these experiments it was assumed that the electric intensity at the surface of a wire is given by the following relation:

$$E = \frac{V}{r_w \log_n \dfrac{D_t}{D_w}} \tag{8}$$

where V = the potential difference between the wire and the tube,

r_w = radius of wire in centimeters,

D_w = diameter of the wire,

D_t = diameter of the tube.

The value for these constants for all of the wires used is given in Table I.

TABLE I
WIRE DATA AND CORONA TUBE CONSTANTS

Diameter of Tube	3.75 in. inside measurement.		
" " Wire	No. 1	= 0.0205 in.	= 0.0521 cm.
" " "	No. 2	= 0.0320 in.	= 0.0813 cm.
" " "	No. 3	= 0.0391 in.	= 0.0993 cm.
Radius " "	No. 1	= 0.01025 in.	= 0.02605 cm.
" " "	No. 2	= 0.01600 in.	= 0.04065 cm.
" " "	No. 3	= 0.01955 in.	= 0.04965 cm.

$\text{Log}_n \dfrac{\text{dia. cylinder}}{\text{dia. wire}}$ No. 1 wire $\text{Log}_n \dfrac{3.75}{0.0205}$ = Log 183 = 5.2095 numeric

No. 2 " $\text{Log}_n \dfrac{3.75}{0.0320}$ = Log 1172 = 4.7638 "

No. 3 " $\text{Log}_n \dfrac{3.75}{0.0391}$ = Log 96 = 4.5643 "

(Radius of wire) $\text{Log}_n \dfrac{D_c}{D_w}$ No. 1 wire = 5.2095 × 0.02605 = 0.1358 cm.

or No. 2 " = 4.7638 × 0.04065 = 0.1936 cm.

$r_w \text{ Log}_n \dfrac{D_c}{D_w}$ No. 3 " = 4.5643 × 0.04965 = 0.2260 cm.

$\dfrac{1}{r_w \text{ Log}_n \dfrac{D_c}{D_w}}$ No. 1 wire $= \dfrac{1}{0.1358}$ = 7.375 1/cm.

No. 2 " $= \dfrac{1}{0.1936}$ = 5.170 1/cm.

No. 3 " $= \dfrac{1}{0.2260}$ = 4.430 1/cm.

Resistance of voltmeter No. Weston = 441.4 ohms 3-volt scale
No. scale divisions for 3 volts = 150 numeric.

Amperes per unit scale division $= \dfrac{3}{441.4} \times \dfrac{1}{150}$ = 0.00004536 amperes.

Resistance of voltage circuit 2,779,000 ohms.
Volts per unit scale division = 2,779,000 × 0.00004536 = 126 volts.

$$E = \frac{\text{Def.}}{r_w \text{ Log}_n \dfrac{D_c}{D_w}} = \frac{\text{Electric Intensity}}{\text{Unit Deflection}} \times \text{Deflection}$$

= No. 1 wire = 126 × 7.375 = 926 volts/cm. /unit deflection.
= No. 2 wire = 126 × 5.170 = 651 volts/cm./unit. deflection.
= No. 3 wire = 126 × 4.43 = 558 volts/cm./unit deflection.

The results were further analyzed in accordance with the relation (9), the work of all other investigators indicating that this relation is correct, and J. T. Townsend having shown that it is in accord with the theory of ionization by collision.

$$E = A\,\delta + B \sqrt{\frac{\delta}{d}} \tag{9}$$

where E = electric intensity,

A = a constant of the phenomena,

B = another constant of the phenomena,

δ = density factor $= \dfrac{3.92\,P}{T}$

P = the absolute pressure in cm. of mercury,

T = the absolute temperature in deg. cent.

Expanding in the above formula

$$E = \frac{3.92\,A\,P}{T} + B\,\frac{\sqrt{\dfrac{3.92\,P}{T}}}{\sqrt{d}} \qquad (10)$$

Divide both sides of the equation by P

$$\frac{E}{P} = \frac{3.92}{T}\,A + B\,\frac{\sqrt{\dfrac{3.92}{T}}}{\sqrt{d}}\cdot\frac{1}{\sqrt{P}} \qquad (11)$$

If $\frac{E}{P}$ is plotted as ordinate and $\frac{1}{\sqrt{P}}$ as abscissa, then for a given absolute temperature T, the resultant curve, if A and B are constant, should be a straight line.

The slope of this line is $B\,\frac{\sqrt{\frac{3.92}{T}}}{\sqrt{d}}$.

The intercept is $\frac{3.92}{T}\,A$.

Also, if the formula is rewritten in the form

$$E = A\,\delta + B'\sqrt{\frac{\delta}{r}} \qquad (12)$$

where r = radius of the wire

$$B' = \frac{B}{\sqrt{2}}$$

Then

$$E = A + B'.\,\frac{1}{\sqrt{\delta\,r}} \qquad (13)$$

With this last formula it is possible to reduce all of the wires at all temperatures to the same law if

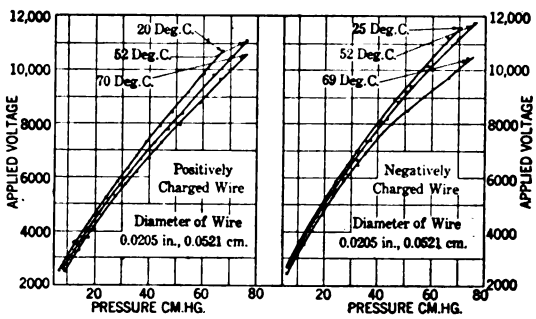

Fig. 9

A and B' are the same for all wires at all temperatures and pressures.

Accordingly, the various quantities have been computed and are given in Tables II, III and IV. Each table gives the electric intensity for corona at the wire, electric intensity divided by pressure $\left(\frac{E}{P}\right)$, electric intensity divided by the density factor $\frac{E}{\delta}$, the density factor δ and $\frac{1}{\sqrt{\delta\,r_w}}$, where r_w is the radius of wire in cm.

Curves showing the relation of applied voltage and

TABULATED RESULTS

Electric Int., $E = A\,\delta + B\,\dfrac{\sqrt{\delta}}{\sqrt{a}}$ kilovolts/cm.

Density Factor, $\delta = \dfrac{3.92 \times \text{pressure}}{\text{absolute temp.}}$

was made variable by changing the pressure and the temperature.

The above formula may be written

$$E/\delta = A + B' \cdot \frac{1}{\sqrt{r\,\delta}}$$

Where A = constant
B = constant
r = radius of wire (cm.)
a = diameter of wire (cm.)
B = constant
$B' = B/\sqrt{2}$

With combined averages

$E = 39.8\,\delta + 10.36\,\sqrt{\delta/d}$ for + corona.
$E = 40.3\,\delta + 11.91\,\sqrt{\delta/d}$ for − corona.

or

$E/\delta = 39.8 + 7.32\,\dfrac{1}{\sqrt{\delta\,r}}$ for + corona.

$E/\delta = 40.3 + 8.17\,\dfrac{1}{\sqrt{\delta\,r}}$ for − corona.

BROWNS' RESULTS

$E = 33.7\,\delta + 11.5\,\sqrt{\delta/d}$ for + corona.
$E = 31.0\,\delta + 13.5\,\sqrt{\delta/d}$ for − corona.

FARWELL'S RESULTS

$E = 35.0\,\delta + 11.4\,\sqrt{\delta/d}$ for + corona.
$E = 31.6\,\delta + 11.9\,\sqrt{\delta/d}$ for − corona.

pressure were drawn for the positively and negatively charged wire, as shown in Figs. 9, 10, and 11. For the same pressure and temperature positive corona appeared at a lower voltage than the negative corona. Although the difference in temperature between two adjoining curves was only twenty degrees, less than 10 per cent upon the absolute scale, at no time is there doubt about the points of observation.

Curves showing the relation of $\dfrac{E}{P}$ and $\dfrac{1}{\sqrt{P}}$ are straight lines within errors of observation. (See Figs. 12, 13, and 14.) The positive and negative corona curves for each wire have a characteristic family. The positive curves show the smallest divergence for the same change in temperature. In the

tabulated results the values of A and B are stated for each wire at every constant temperature observation for a variation of pressure from 10 centimeters to

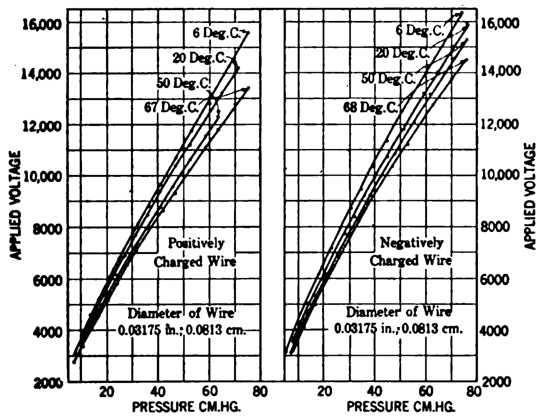

FIG. 10

70 centimeters of mercury. It is seen that B si always greater for negative corona.

The curves shown in Figs. 12, 13, and 14 were

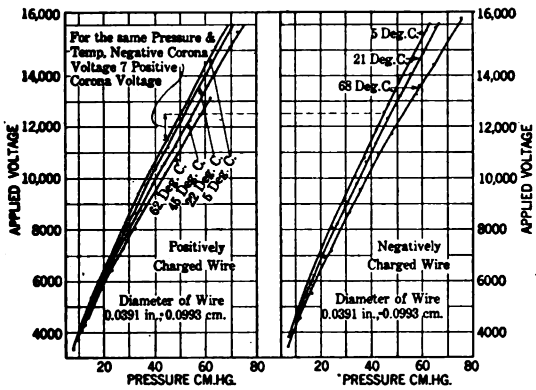

FIG. 11

reduced as explained by plotting $\frac{E}{\delta}$ and $\frac{1}{\sqrt{\delta r}}$ as ordinates and abscissas respectively. This allows

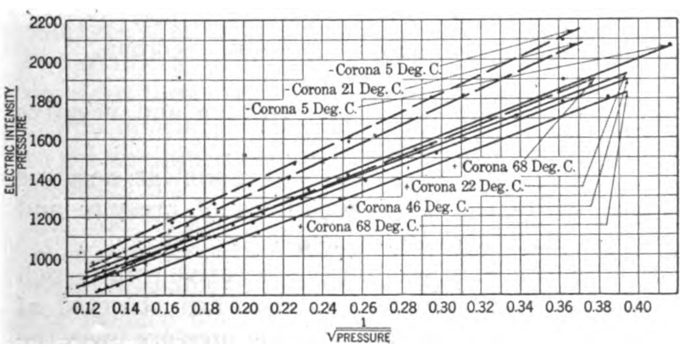

FIG. 12—POSITIVE AND NEGATIVE CORONA

Showing linear relation between

$\frac{\text{Electric intensity}}{\text{Pressure}}$ and $\frac{1}{\sqrt{\text{pressure}}}$

at different temperatures.

Diameter of wire = 0.0993 cm.

all of the points of the above observations to fall within a narrow zone whose width may be taken as an index of the accuracy of observations. (See Figs. 15, 16,

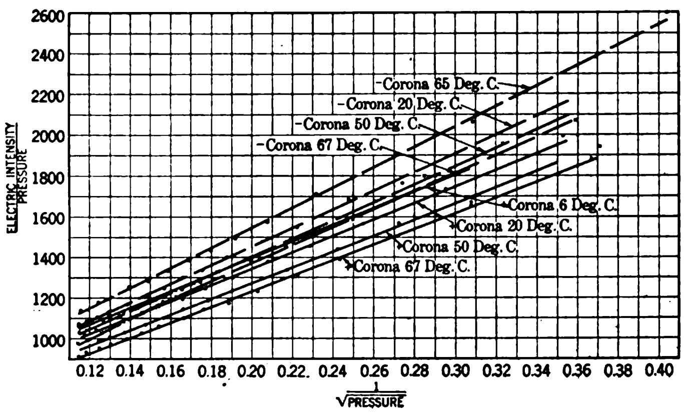

FIG. 13—(SAME AS FIG. 12, EXCEPT DIAMETER OF WIRE = 0.0813 CM.)

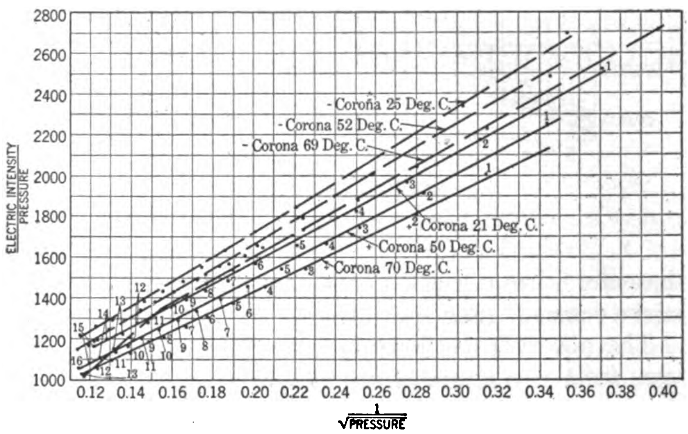

FIG. 14—(SAME AS FIG. 12, EXCEPT DIAMETER OF WIRE = 0.0521 CM.)

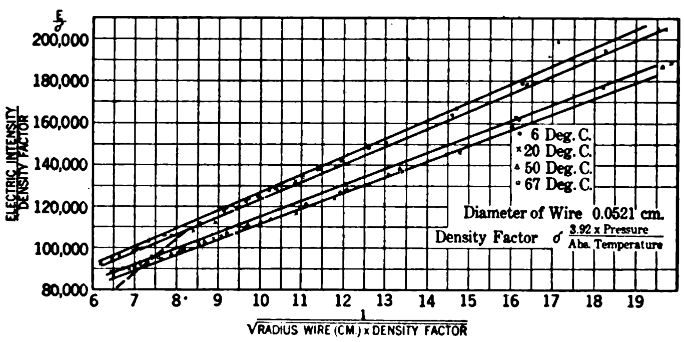

FIG. 15

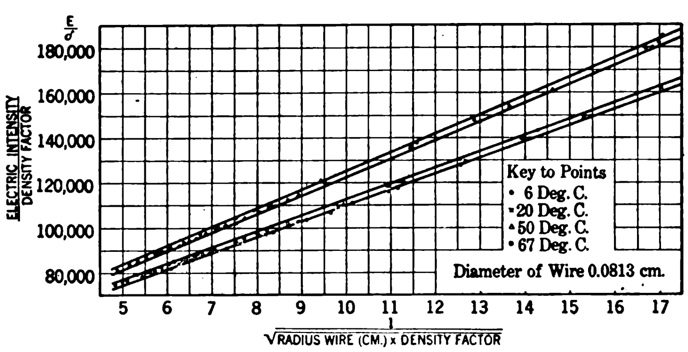

FIG. 16

and 17.) This zone is also a straight band which indicates that the original premises were well founded. In the tabulated results itsefra hwatohenesi iretc the average value for A is not very different but the average value for B has a distinct separate average for the positive and the negative corona respectively. The table also shows the value for B' in the later adopted form

$$\frac{E}{\delta} = A + B' \frac{1}{\sqrt{\delta\, r}} \qquad (13)$$

It should also be noticed that at the highest temperatnre of 69 deg. cent., especially with the smaller

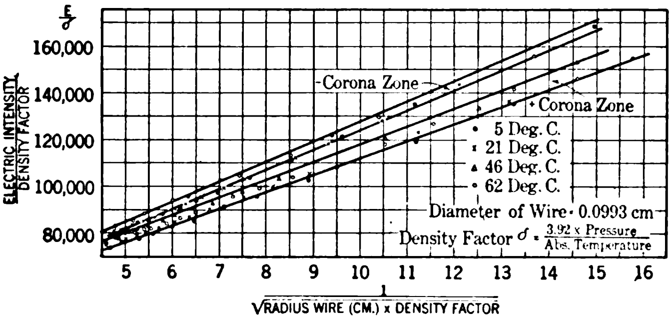

FIG. 17

diameter wire, a break in the continuity of the corona curve occurs. (See Fig. 14.)

The observations leading to these apparent departures from the fundamental law of formula (13) were repeated several times, and in each case yielded the results indicated. There is no obvious explanation why these breaks should appear in one set of curves and not in others in their neighborhood. Investigation of this interesting question is being continued.

DISCUSSION

The fact that positive corona starts at a lower value is in accord with the investigations of Farwell, Schaffers, Watson and Brown. It is in accord with the general theory of Townsend that negative ions are the active agents in the starting of corona. If the wire is positively charged they will move into an ever increasing field from a large region and hence will multiply more rapidly than if the reverse were true. According to Brown and Schaffers this principle fails when the value becomes less than a definite value. The results of this investigation indicate that the positive corona is always lower than the negative corona. Brown mentions great difficulty in securing definite negative corona readings. It was noticed in this investigation and discovered earlier by Whitehead[3] that negative corona occurs very abruptly from what seems a kind of supersaturated condition. If the negative corona is once formed the potential may be decreased below this corona-forming value with the corona phenomenon still persisting. The exact cycle of this phenomenon is at present under further investigation.

It is interesting to compare the value of the electric intensity as observed by Brown's relation upon the 0.0993-cm. wire. Brown states his positive corona formula

$$E = 33.7\,\delta + 11.5\sqrt{\frac{\delta}{d}} \text{ kilovolts per cm.}$$

Upon substituting the above value for d and using a density factor of unity

$E = 70.15$ kilovolts per cm.

If Farwell's relations are used

$$E = 35\,\delta + 11.4\sqrt{\frac{\delta}{d}}$$

$E = 71.15$ kilovolts per cm.

The results of this investigation give

$$E = 39.8\,\delta + 10.36\sqrt{\frac{\delta}{d}}$$

$= 72.6$ kilovolts per cm.

At pressures lower than atmosphere, both Brown's and Farwell's results indicate higher corona voltages than those found in these experiments. It should be stated that this is the only observation in which the field of these experiments touches that of Brown and Farwell.

CONCLUSIONS

1. The critical corona-forming electric intensities of these wires, ranging in size from 0.0521 to 0.0993 cm., at several constant temperatures in the range 5 deg. to 70 deg. cent. and at various pressures for each temperature have been investigated under continuous positive and negative potentials.

2. The critical surface intensity at which corona started upon the above wires can be summarized in the relation

$$E = 39.8\,\delta + 10.36\sqrt{\frac{\delta}{d}} \text{ for + corona}$$

$$E = 40.3 \quad + 11.96\sqrt{\frac{\delta}{d}} \text{ for − corona.}$$

3. The constant A in the positive and negative corona relation is the same.

4. Within the range of this experiment negative corona, under the same conditions of pressure and temperature, always occurs at a higher value.

5. The curves of positive and negative corona each form a separate family of curves when observed at the same temperature with variable pressure upon the same wire.

6. The observations give accordant results with Farwell and Brown when used under pressure and temperature conditions of observation at which their data were taken.

7. The results of the investigation are in accord with Townsend's theory of secondary ionization.

Some Phases of Railroad Telegraph and Telephone Engineering

BY STANLEY RHOADS

Telegraph & Telephone Engineer, New York Central Lines

(*Concluded from page* 325 *of JOURNAL for April*, 1921)

SELF-BALANCING DUPLEX

Based upon the idea of a duplex being a three-wire circuit, successful use has been made of a real line instead of the usual artificial line resistance box and condensers which are standard equipment in duplex sets. This "real" balancing line balances the regular line almost perfectly under changing weather conditions, needs no additional balancing at such times and hence can be designated "self-balancing." It also balances for inductive disturbances to which both line and balancing line are exposed and for line irregularities such as short lengths of cable. This assumes that the duplex line and its balancing lines are alike in characteristics; are on the same pole line; have the same length; kind of wire, and, in fact, are twins. The two sides of a composite are very good for this type of set-up, but the plan is also applicable to any two similar circuits, such as straight wires or simplexes provided they are reasonably alike in kind.

One difficulty experienced in lining up a duplex is to get an adjustment of resistance and capacity in the artificial line which will so nearly balance the actual line that no kick will be felt in the home polar relay when the home pole changer is operating. It is almost impossible to get such a balance, and furthermore, the balance must be changed for changing weather conditions. It is, therefore, unsatisfactory to work a duplex circuit having a repeater station on it that does not have an attendant the full period of the day in which the circuit is expected to give service.

This plan of self-balancing duplex is especially valuable for circuits that are unattended at repeater stations for a part of the day and on Sunday. It has been the custom in some instances to cut the repeater out during the hours the station is unattended, but this makes a long and unsatisfactory circuit.

The plan may be considered an extravagant use of wire, because it uses two wires for one duplex, but it is only suggested as an expedient for use where some circuits are idle after business hours, as many duplexes are at night and on Sunday, at which time they can be put to productive use for balancing a wire that must give twenty-four hour service.

Some oscillograms have been taken that illustrate the effect of lack of good capacity balance in the artificial line, and the perfection of the balance with a real line instead of an artificial line. It should be kept in mind that in the latter the balance is continuous and unchanging, whereas the artificial line needs attention intermittently.

In oscillogram No. 469 of Fig. 18 the outgoing line wave of a bridging quadruplex set on a 140-mile, No. 8 B. W. G. iron wire, high-resistance simplex, is trace No. 1 while the home key is operating. Trace No. 2 is the artificial line under the best balance that the attendant was able to get with the milliammeter as a guide. Trace No. 3 is the wave in the polar relay and shows plainly that the home pole-changer affects it considerably, evidenced by the kicks in trace No. 3 which occurred on the reversal of the line wave.

Oscillogram No. 470 is the same set on the same circuit with no difference except that all the capacity was removed, which greatly amplified the kick in the polar relay, trace No. 3, as would be expected. Oscillogram No. 540 is the same circuit with duplex sets. Oscillogram No. 588 shows the results with the self-balancing duplex on a 140-mile, No. 9 A. W. G. copper wire low-resistance type phantom, composited, in which it is readily apparent that the kick in the polar relay is very slight and a great improvement over the best balance that could be obtained on the artificial line. The slight waves in the polar relay wave be-

tween reversals of line current are probably reflected waves.

In Fig. 26, which indicates self-balancing duplexes applied at an unattended repeater station, the artificial line is cut off at switches No. 11 and No. 12, where the real lines to be used as balancing lines are cut in, which requires a special connection in existing duplex sets. Terminal stations are shown with duplex sets connected to these balancing wires, with no change except to cut off the battery at the seven-point switch and put on ground contact, which is regularly provided for in the seven-point switch. If lines No. 2 and No. 4 are regularly duplexed, their duplex sets are simply grounded at the seven-point switch. The resistance and capacity in artificial lines No. 8 and No. 10 can roughly approximate the values required in the artificial lines No. 7 and No. 9. This does not need to be exact, although it is about as easy to make it so as to have it inexact.

This set-up can be quickly arranged and, it is believed, is worth the trouble where circuits are idle, although the station may be attended, because it gives better service and needs no attention. It is quite often the case that the night and Sunday repeater attendants are the less experienced men of the force, and service will be better if they do not have to attempt adjustments of the duplex apparatus or repeaters. The plan is equally applicable and advantageous for differential and bridging duplexes.

No. 5-U Retardation Coil in Bridging Duplex and Quadruplex is Also Auto-Transformer

The action of the No. 5-U coil of bridging duplexes and quadruplexes was an object of curiosity, the work performed by the coil being difficult to determine with certainty, and a large number of oscillograms was taken to reach conclusions. From these it can safely be asserted that the No. 5-U coil functions primarily as an auto-transformer and incidentally as a retardation coil.

The traditional explanation ever since Brown designed this circuit arrangement is that an incoming wave from the line meets great opposition in its attempt to flow through the line side of the No. 5-U coil, because of the high impedance of the latter, and as a result almost all of the incoming current rushes into the polar relay which is connected across from line to artificial line. The explanation stopped at this point and neglected to state where this rush of current through the polar relay proceeds to. It does not go through the artificial line to ground, because the current is coming toward the No. 5-U coil at this time, and while this current is influenced slightly in value by the incoming line current it is not reversed nor is it greatly reduced. If the impedance of the line side of the No. 5-U coil were effective in stopping the inrushing line current, the artificial line side of it should be equally effective in stopping the rush that passes through the polar relay. No explanation has been made for the condition of outgoing current which also occurs due to the operation of the distant pole-changer.

In the quadruplex, the condition existing with the home keys and distant common key closed and distant polar key working will be discussed first. Oscillogram No. 471 of Fig. 28 shows the current in the line as trace No. 1, in the artificial line as No. 2 and in the polar relay as No. 3, of a bridging quadruplex on an Indianapolis-Bellefontaine, 140-mile, No. 8 B. W. G. iron wire telephone pair, simplexed with the ordinary high-resistance simplex used with direct-current selectors as shown in Fig. 10 but without the composite equipment, and balancing at 4400 ohms with one microfarad and 500 ohms in the first condenser, and 400 ohms and 3/4 microfarad in the second condenser. The distant polar key is sending the impulses and the other keys are closed. It is apparent from No. 471 that the artificial line current is only

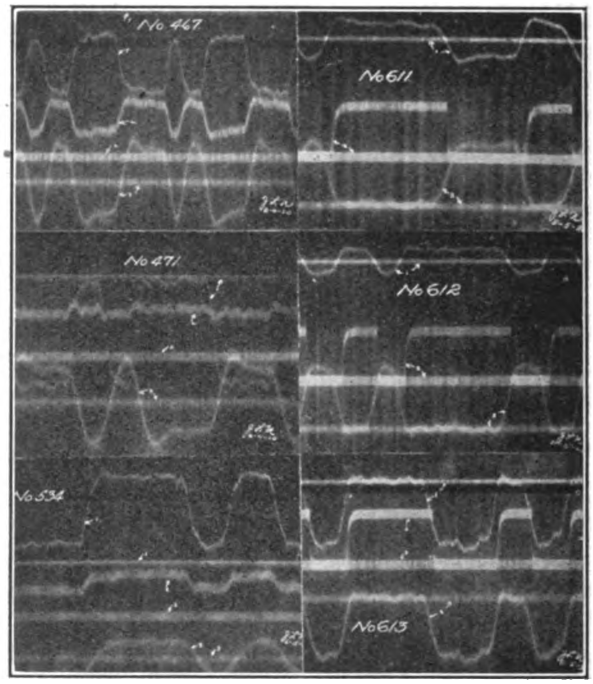

Fig. 28

slightly changed by the change of line current with operation of the distant polar key. Oscillogram No. 467 was taken under the same line conditions as No. 471 but shows the current in the line side of the No. 5-U coil as trace No. 1, the artificial line side as No. 2 and in the polar relay as No. 3. The difference in the values of current in the artificial line as shown in No. 471 and the artificial line side of the No. 5-U coil in No. 467 is very marked, and the difference represents the polar relay current.

With all keys closed the current is "upward" in the polar relay, *i. e.*, the direction indicated by an arrow on Fig. 29 pointing to the top of the page. It is also flowing toward the home pole-changer through the No. 5-U coil windings. Fig. 29 gives the current values and direction of flow on a bridging quadruplex during the steady state, for the different positions of

the keys, as actually measured on a working circuit. Fig. 30 gives actual current values in a differential quadruplex on the same circuit, for comparison.

Now, if the distant polar key opens, positive potential is applied there and current begins to flow in from the distant station. The potential wave will cause current to flow through the line side of the No. 5-U coil and will quickly increase the potential across this coil, during which time the current will decrease through the polar relay, and when the potential across the line side of the No. 5-U coil equals the potential across the artificial line side, the polar relay current at that instant will be zero but rapidly changing in direction. The transient state continues, that is, there is no hesitation at the zero point and the current reverses in direction through the polar relay.

When the distant polar key closes again, negative potential

is applied there and the line current decreases and becomes nearly zero. The traditional explanation does not mention this action which leaves the impression that the movement of the polar relay armature both to and from the marking contact is due to "incoming" waves of current. In fact, the movement away from the marking contact is due to increase or rise of incoming current in the line, and the movement toward the contact is due to decrease or fall of line current, provided the home polar key is closed. If the home key is open, then the movement of the polar relay armature is due to just the reverse set of current actions, *i. e.*, the movement away from the marking contact will occur with decrease of outgoing line current and will move toward it with increase of outgoing line current. The current in the line will be flowing from the home station when the home key is open.

It will be remembered that the No. 5-U coil windings are both

wound on the same core and have a common terminal. The incoming and increasing current in the line side when the distant polar key opens, tends to build up a magnetic field in this core. This induces current in the artificial line winding by mutual induction or transformer action and in the same directional relation as in the line side; *i. e.*, if the line current is increasingly flowing toward the common terminal of the two windings, the generated current in the artificial line side will be toward this point, as follows from the laws of mutual induction. The magnetic flux of this generated current is nearly equal and opposite to that in the line side, and hence, the net change in flux is slight. As the current rapidly increases in the line side of the coil, it also rapidly increases in the artificial line side, thus creating a large difference of potential between the two line terminals; it is to be remembered that the common terminal can have only a potential common to both. This change of potential across the line terminals, which is across the polar relay, causes the reversal of current through the polar relay and throws the armature to the spacing position.

The oscillograms fail to show any great "rush" considered as rate of change of current value, but do show that the current continues to increase in value after reversal has occurred, to perhaps 20 per cent higher value than it does if the No. 5-U coil is replaced by 500-ohm resistances. If the No. 5-U coil is removed and two 500-ohm non-inductive resistances are put in its place, the current through the polar relay loses its tendency to rise beyond the value it has after reaching the steady state. Oscillograms No. 611 and No. 612 illustrate this, with No. 1 as polar relay trace, No. 2 as the polar relay local sounder circuit trace and No. 3 as the line trace. The No. 611 has the No. 5-U coils and shows that the polar relay current at each reversal continues beyond its ultimate value considerably and then gradually recedes. The No. 612 has 500-ohm resistances and the current in the polar relay reverses and reaches the steady value without the tendency to "bulge" beyond that value.

These two oscillograms were taken on one side of the low-resistance composited phantom, Indianapolis to Bellefontaine, No. 9 A. W. G. copper a-c. selector telephone dispatching line with the bridging duplexes balancing at 1800 ohms, three microfarads and 100 ohms in the first condenser, and two microfarads and 600 ohms in the second condenser, with 160-volt main battery at each end. The polar relay has an ordinary or usual adjustment, and both No. 611 and No. 612 show that the polar relay armature is reversed before the current change has ceased in the polar relay, and it is evident that the bulge of current in the set with the No. 5-U coil serves no useful purpose other than to hold the polar relay armature more solidly against its contact after it gets over. From the evidence gathered in these investigations it is not apparent that the current changes at any greater rate in the set with the No. 5-U coil than in the one with the 500-ohm non-inductive resistance. A similar record of a differential duplex and its polar relay local sounder circuit is given in No. 613 for comparative purposes. It was taken on the same circuit as were No. 611 and No. 612. In No. 613, traces No. 1 and No. 3 are both the line current.

For the bridging quadruplex the result of comparison of the No. 5-U coil and the 500-ohm resistances is shown by No. 469 of Fig. 18 for the No. 5-U coil and No. 534 of Fig. 28 for the 500-ohm resistances, both taken on the 140-mile, No. 8 B.W.G. high-resistance iron simplex circuit. In these, trace No. 1 is the line side of the No. 5-U coil, No. 2 is the artificial line side of the No. 5-U coil and No. 3 is the polar relay current. The common or neutral keys are closed.

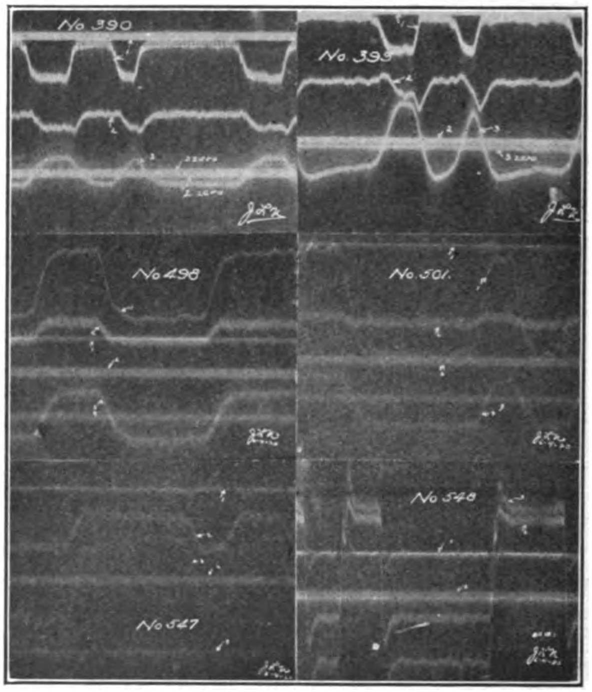

Fig. 31

This tendency to bulge or exceed the ultimate steady state value is more striking in the Goslin quadruplex, as illustrated in No. 390 of Fig. 31 for the non-inductive winding, and No. 393 with the No. 5-U coil. In this arrangement the polar relay and neutral relay are in series across the terminals of the No. 5-U coil and get less current in the bridge after the steady state is reached than does the regular quad, and due to the No. 5-U coil tending to equalize the current through its two windings during the transient state, the polar relay current is considerable.

It will be noted in No. 467 of Fig. 28 that after the first rush ends, the line side current in the No. 5-U coil continues to increase slowly and the artificial line slowly decreases, both changing by about the same

amount, until the steady state is reached. This time to reach the steady state in these bridging sets is longer than the average dash, as seen in the letter "a" which is being repeated in these oscillograms.

Two quadruplex sets were made up of non-inductive resistances throughout, simply maintaining the skeleton outlines of the bridging quadruplex; that is, there were no coils or relays used, simply resistances of the same values as the pieces of apparatus they replaced. These were placed on the same No. 8 B. W. G. iron wire simplex circuit as that on which No. 467 and No. 471 of Fig. 28 were taken. No. 498 of Fig. 31 corresponds to No. 467 as to location of recording elements of the oscillograph, and No. 501 similarly corresponds to No. 471. In No. 498 and No. 501 it is evident that the rate of reversal of current through the polar relay branch of the circuit is the same as with the regular polar relay and No. 5-U

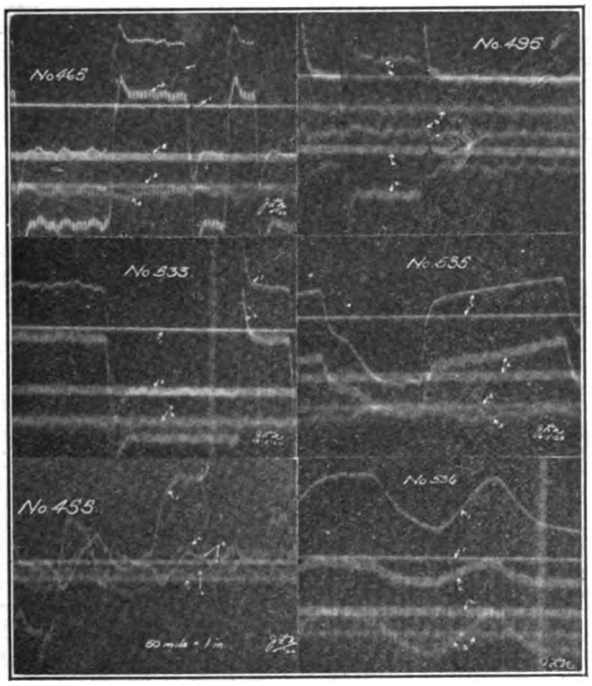

Fig. 32

coil, but the change ceases sooner with the non-inductive circuit, although the line waves are very closely the same in both arrangements.

Comparison shows clearly how the steady state is quickly reached in the polar relay in the non-inductive resistance circuit used in place of the No. 5-U coil illustrated in No. 498; whereas, there is considerable slant or gradual change in the inductive No. 5-U coil illustrated in No. 467.

A search coil of 250 ohms was wound on a No. 5-U coil of a duplex set and connected to the oscillograph, giving the result shown in No. 547 of Fig. 31 as No. 1 trace, with the distant station sending on the polar key. This shows that the change in magnetism in the core of the No. 5-U coil is very slight, consisting of small humps in the trace No. 1 at each reversal of the line current, while the current in the two sides fluctuates widely, which indicates that the coil is a very efficient transformer and as in power transmission, comparatively large power is transformed with a relatively small magnetizing current.

In the case of the current waves set up by the action of the home polar key when sending as shown in No. 548 of Fig. 31, the magnetism is considerable, as shown by the large sharp peaks of trace No. 1 made by the search

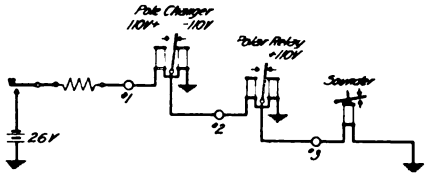

Fig. 33—Polar Relay Test Circuit

coil. This is somewhat due to the lack of proper and exact "balance," *i. e.*, the capacity, resistance and inductance of the artificial line is not exactly the same as the real line and the terminal apparatus at the distant end of the line.

These peaks of magnetism in the core of the No. 5-U coil cause the rounding off of the line wave of the

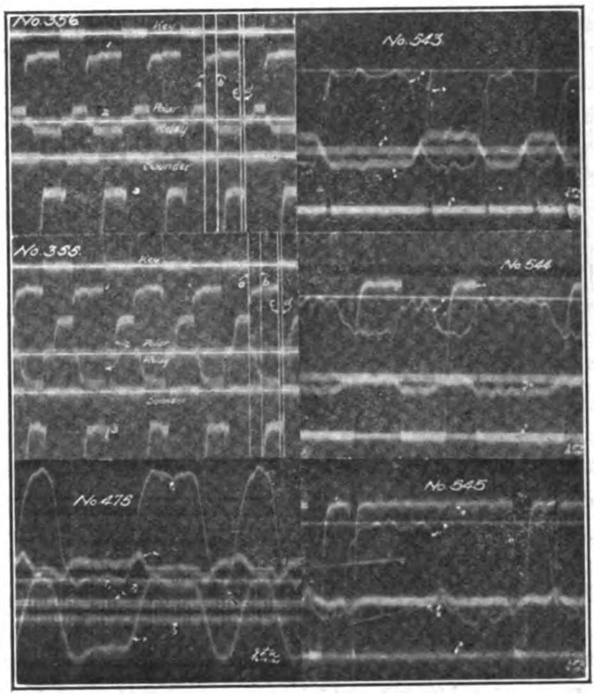

Fig. 34

home key operation, which is one of the chief features aimed at in the bridging sets. If no magnetic flux resulted due to the outgoing wave, the coil could be considered as non-inductive to outgoing waves and would show no great difference in the outgoing wave from that of the differential sets which have very sharp peaked out going waves. Tests with an actual line instead of an artificial line show that the kicks in

the polar relay resulting from the home pole-changer are negligible, as illustrated in No. 588 of Fig. 18, but that the outgoing line current is rounded off as much as in sets that have artificial lines. Therefore, it is not lack of balance that causes the flux in the No. 5-U coil and the rounding off of the outgoing wave. It is, perhaps, the leakage flux in the No. 5-U coil which affects both the line and artificial line sides equally, if the balance is exact.

As a further illustration of the conclusion that the No. 5-U coil has effect in rounding off the outgoing waves No. 465, No. 495 and No. 533 of Fig. 32 can be compared. All three are records made on the previously mentioned 140-mile, No. 8 B. W. G. iron wire simplex circuit, and trace No. 1 is the line side of No. 5-U coils, No. 2 is the artificial line side of No. 5-U coil, and No. 3 is the polar relay circuit. The distant common key was open in all three, the home polar key sending and the other two keys were closed. The peaks of the outgoing waves are rounded off in No. 465, which is the regular bridging quadruplex. They are sharp in No. 495 which is a skeleton resistance quadruplex mentioned above and are also sharp in a regular quadruplex with 500-ohm resistances instead of a No. 5-U coil, as illustrated in No. 533.

In a quadruplex of either bridging or differential type and in the differential duplex, it is readily apparent that the relays which are in the line differentially, that is with one coil in the line and one in the artificial line, act as transformer to some degree. This follows because the two windings have a common core, and current in one winding cannot fail to generate current in the other winding. The extent of this action has not been definitely determined.

Two separate No. 5-U retardation coils were also tried in a quadruplex with one winding of each connected in circuit and the other winding standing open, on the 140-mile No. 8 B. W. G. iron simplex. The result is shown in No. 536. It was not possible to work this quadruplex, because it took too long for the current waves to build up and die out in the retardation coils. The result of the home polar key sending is shown in No. 535, which is plain explanation of the failure of the circuit to telegraph. Trace No. 1 is the line side coil, No. 2 is the artificial line coil and No. 3 is the polar relay. The home key causes wide variation in the current in the home polar relay. These two records disprove the theory that the No. 5-U coil is a retardation coil only.

Modification of the outgoing wave is necessary for circuits such as the bridging duplex is designed for, that is single wires and simplexes, and for these perhaps some suitable retardation coil and condenser can be designed for insertion between the pole-changer and the line relay. The ideal design would be inductive to home sending and non-inductive to received signals. The vacuum tube may solve the problem.

In comparison of bridging and differential duplexes it is seen that the received line waves are practically equal and alike in shape in both, if used on the same circuit and with the same voltage. A question is, which makes more efficient use of this wave? The polar relay has its coils in series on the standard bridging duplex. One coil of this relay would require twice as much current in order to have equal force. The net operating current in a differential set is the difference between the line and artificial line current and can be considered as acting in one coil only of the polar relay. If this net operating current is greater than the bridging set polar relay current multiplied by 2, it has greater force than the

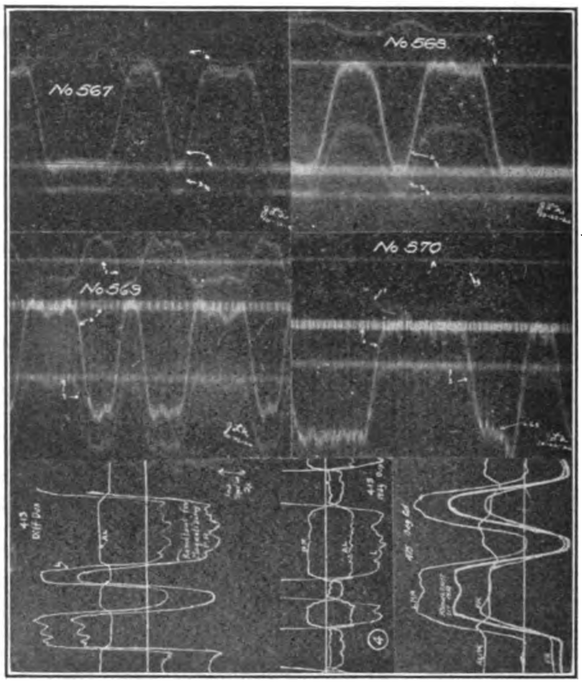

Fig. 35

latter. Tracings from oscillograms Nos. 413 and 415 are given in Fig. 35, and clearly indicate that the differential relay net operating current of No. 413 is more than twice the polar relay current of No. 415. From the records taken it appears that the bridging polar relay does not get as much force as the line coil of a differential set, due to the divided circuit between the No. 5-U coil and polar relay, both of which share the line wave. Therefore, the differential probably makes more efficient use of the line wave than does the bridging duplex.

Polar Relay Speed of Reversal

The quadruplex depends for its success upon the important fact that the fluctuations in the line current due to the insertion and removal of resistance in the distant station main battery, are not distinguishable to the ear in their effect upon the polar relay and its local sounder. The fluctuation is generally set at a 3 to 1 ratio, that is, the current is three times as great

when the distant neutral key is closed and the resistance cut out as when it is open with the resistance in. In some cases the ratio of 4 to 1 is used. In a bridging quadruplex the bridging relay current will be 16 or 17 milliamperes with the distant neutral key closed and 5 to 6 with it open. The polar relay must and does follow the distant polar key without recording this 5 to 16-milliampere variation. Tests were made to demonstrate this, using the circuit of Fig. 33, with the result given in oscillograms No. 355 and No. 356 of Fig. 34. The key circuit was 150 milliamperes, the polar relay was 30 milliamperes and the sounder circuit, 325 milliamperes in No. 355. In No. 356 the polar relay current was reduced to 10 milliamperes. The distance *a-b* in both represents the reversal time of the polar relay armature when the key closes. The interval *c-d* is the reversal time when the key opens. There is no difference noticeable in the *a-b* intervals of the two records, and, likewise, very little difference in the *c-d* intervals of the two, which verifies what is known from listening tests.

Defects of Quadruplex

The neutral side of a quadruplex depends upon increase and decrease of line current strength and should be independent of the direction of the current. One weakness of the standard quadruplex is that the neutral relay is not independent of the reversals of line current which are produced by the operation of the polar side of the circuit. Means are necessary to overcome the resulting opening of the neutral side local sounder circuit when the current reverses in the neutral relay. The present standard of the Western Union Telegraph Company appears to be a development of the Gerrett Smith bridging condenser plan in combination with the Diehl "bug trap" repeating sounder. With the "bug trap" the contact point is the back-stop of the neutral relay armature, and therefore, this armature may, in fact, leave its front stop when a current reversal takes place, and if it pulls up again without striking the back contact, no false signal results. The bridging condenser holding circuit includes a coil on the neutral relay, which gives the armature a pull, due to the condenser charging current that occurs with change of line current, and this pull assists in keeping the armature from striking the back contact during current reversal.

The present design of neutral relay has the holding coils mounted above the line coils, and the armature is extended up to the pole faces of these coils. This results in a comparatively slow or sluggish relay due to armature inertia, and while fast enough for hand sending, for which it was designed, it is too slow for fast hand-operated sending machines or "Vibroplex" use, commonly called "bug" sending.

The standard Western Union bridging quadruplex has the polar relay bridged across the line and artificial line terminals of the No. 5-U coil with its two coils in parallel, and has one winding of the neutral relay in the line and the other in the artificial line. The current readings of small Fig. A of Fig. 29 indicate the steady current values which are with all keys closed, 16 milliamperes in the polar relay and 52 milliamperes, the difference between 56 and 4, in the neutral relay, which is net operating current in one coil of the latter. The 16 milliamperes in the polar relay with coils in parallel are equivalent to 16 milliamperes in one coil, if the same force were applied to one coil only as is the case with the neutral relay. The neutral relay, therefore, has a marginal advantage of 36 milliamperes acting in one coil, over the polar relay due to being in the line. Oscillograms, as well as direct-current measurements, confirm the above advantage claim as shown in the tracing of Fig. 35, at the bottom of the page, traced from oscillogram No. 475, using one base line for all three waves of current, on a bridging quadruplex on the 140-mile, iron wire simplex. On this tracing the difference between the line and artificial line current has been plotted and is marked "Resultant in N. R.," showing that the neutral relay net operating current apparently is greater than the polar relay current.

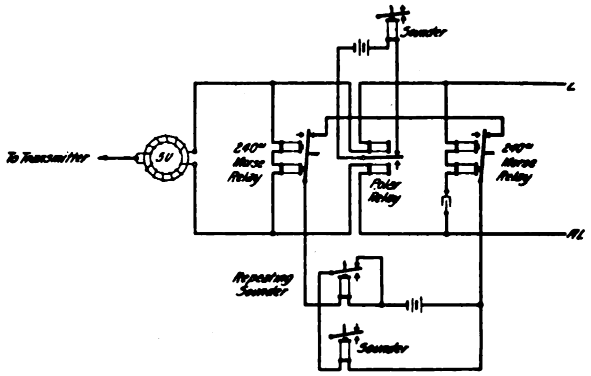

Fig. 36—Reverse Quadruplex

Reverse Quadruplex

The polar side of a standard bridging quadruplex is believed to be weaker than a differential duplex, because of smaller current margin, and in the endeavor to strengthen it, advantage was taken of the apparent higher current in the line, and the positions of the polar relay and the neutral relay exchanged, placing the polar relay differentially in the line and the neutral relay across the No. 5-U coil.

The neutral relay was next separated into two parts, consisting of two standard 240-ohm Morse relays, No. 4-C, one in the bridge and the other in the holding condenser circuit, with the result shown in Fig. 36 called a "reverse" quadruplex, which is a faster quadruplex than the one with the standard neutral relay. This novel arrangement of the holding relay in series with the holding condenser and separate from the neutral relay, functions when the line current reverses, due to the distant pole-changer operating, and pulls up the holding relay and opens the neutral relay local circuit at the moment it tends to close when the

line current reverses. Tests were made with a reverse type quadruplex on the 140-mile iron wire simplex with the distant station sending on the polar key, first with the holding relay contact short-circuited and not functioning, and second with the neutral relay contact short-circuited and not functioning, but with the holding relay operating. The first is No. 543, of Fig. 34, in which trace No. 1 is line current, trace No. 2 is bridge relay current and trace No. 3 is the neutral relay local circuit. The relation of waves in traces Nos. 1 and 3 shows the time at which the neutral relay releases, due to line current reversal. The second case is No. 545, in which trace No. 1 is line current as in No. 543, trace No. 2 is holding relay circuit, which has the condenser in series with it, and trace No. 3 is the neutral relay local circuit. The break in the local circuit here comes at practically the same place in the line wave that the circuit tends to close in No. 543.

Actual results confirm the fact that these two circuits function in harmony, producing a practicable "bug trap." The repeating sounder is retained as in the standard quadruplex. The closure of the neutral relay local circuit with operation of the distant neutral key, is illustrated in No. 544 as trace No. 3, in which the line current is trace No. 1, and the bridging relay, in this case the neutral relay, is trace No. 3. This type of quadruplex will follow fast "bug" sending on the neutral side.

The second weakness of a quadruplex is lack of accurate artificial line balance, and a means of determining the accuracy of the balance better than the standard milliammeters is greatly needed for both duplex and quadruplex. It is not possible with the milliammeters to distinguish between a balance on an artificial line and the balance obtained by the use of an actual line. The results as observed on the Morse and as recorded by the oscillograph, show there is a very decided difference in the best artificial line balance and the actual line balance. A meter with a beam of light instead of a swinging coil and pointer, based on the oscillograph vibrator idea, is suggested. The undulator for multiplex circuits perhaps may be advantageously used with ordinary Morse duplexes.

Terminal Resistance Unbalance

The terminal resistances, which are in the main battery taps as protection from short circuits at the pole-changer contacts, are a third detrimental factor in the quadruplex and also in the duplex, but more so in the quadruplex. In Fig. 29 it is seen that the current in the negative battery is 60 milliamperes with all keys closed, and is 137 milliamperes when the distant polar key is open. The 137 milliamperes cause a greater potential drop across the battery protection resistance and result in less effective voltage to the artificial line, which upsets the balance to a considerable extent as seen in the resultant neutral relay wave of No. 475 traced in Fig. 35. This causes the current to be light with the keys all closed and heavy when the distant polar key is open. If the home polar key is open, the conditions of heavy and light are the reverse, that is, the current is heavier when the distant polar key is closed than when it is open. The effect is apparent in the polar relay, and although less noticeable, is very detrimental in the neutral relay by reducing the working margin to the extent of the difference between the light and heavy current. The remedy suggested is to use No. 2-A or similar circuit breakers in place of terminal resistance, and use generators or battery with negligible internal resistance.

Cause of Light and Heavy Writing

A fourth factor detrimental to good quadruplex results and also to duplex working, is the tendency for the polar relay to write heavy when the home polar key is closed and to write light when it is open, caused by the distant office pole-changer armature travel being too great, or its speed of travel too slow. This action is independent of and in addition to the terminal resistance unbalance. If all keys are closed, there is no current in the line. Assume that the distant pole-changer now opens; *i. e.* leaves the negative battery, and is held midway between contacts a definite length of time, that is, on neither positive nor negative battery. The home battery and the stored energy of the line and equipment will be the only forces acting. The current values that existed the instant previous to opening the key, were comparatively small, there was no current in the line, and the magnetic inertia tends to keep the current flowing as it was, hence no great effect is noted, not enough to throw or start the home polar relay armature. Now, let the distant pole-changer strike the back contact which is positive battery, and the line current will jump up perhaps to 100 milliamperes and promptly throw over the polar relay armature. If the pole-changer is now "opened" again without making contact on either polarity, half the voltage causing the 100-milliampere line current will be cut off, the current will quickly decay, and the home battery will weaken the current in the polar relay and tend to start it in its reversal. If the pole-changer now closes, *i. e.* makes contact on negative battery, the line current will become zero and the polar relay will be reversed by the home battery. In this explanation the point is that when the distant pole-changer leaves the negative or closed pole, the effect is negligible until the positive pole is in action; this tends to lengthen the marking signal at the polar relay, and the movement of the pole-changer from the positive or open pole toward the closed or negative pole, causes quick action in the polar relay, tending to make it close. Thus, the effects are to lengthen marking signals by quick closing and delayed opening.

Assume both the pole-changers to be on the open or positive battery and the line current zero. Now,

if the distant pole-changer opens and is held midway between contacts a moment, the spacing signal at the home station will continue. When the pole-changer is placed on closed or negative battery, the line current will jump up to about 100 milliamperes and the home polar relay will be reversed to the marking contact. If the distant pole-changer is now held open again, the 100 milliamperes will be cut off and the home battery also will tend to weaken the current in the home polar relay. When the open or positive pole is again put in action at the distant pole-changer, the force necessary to complete the action of reversing the home polar relay will be slight and the result prompt. In this explanation it is seen that slow or delayed movement of the distant pole-changer from the positive or open pole to the negative, tends to make the marking signal slow to begin, and the delayed action in closing again tends to cut off the marking signal almost as soon as if no delayed action occurred. Thus, by delaying the start and not delaying the end of a marking signal, the signal is made shorter, which is the reverse of the condition with the home polar key closed. The result is heavy signals with the home polar key closed and light signals with the home polar key open. The remedy is close adjustment of the pole-changer, but this will not change the terminal resistance unbalance trouble.

From oscillogram No. 455 of Fig. 32, which is the record of line current as trace No. 1, bridge relay as trace No. 2, and holding relay as trace No. 3, on the 140-mile iron wire simplex, it would appear, at first glance, beyond expectation for the relays of a quadruplex to follow such apparently senseless waves. The experiments so far made encourage the belief that it is not impossible. In the first place, if an artificial line as good as an actual line is obtained, half the problem is solved. The terminal resistance unbalance, pole-changer travel unbalance and unnecessary relay inertia are other factors which are capable of improvement.

Inductive Disturbance in Telephones from Differential Sets

It is the experience on the New York Central Lines that differential operation on some classes of circuits causes considerable induction in adjacent circuits, in some cases interfering to a serious extent with the operation of telephone circuits carried on the same pole lines. The increasing number of multiplex printer circuits which are differential-operated increases the disturbances.

Bridging duplexes do not seem to cause appreciable difficulty of this nature, but the speed of operation of the bridging sets may not be as high as with differential working. Certain tests have shown that the differential system is satisfactory from an induction standpoint on paralleling telephone circuits when used on composited phantom wires, that is, on the Morse legs of two pairs making up a phantom of which each pair gives one Morse circuit; also on Morse circuits made up of each of two wires which form a long-distance telephone pair. It is the intention, therefore, to use the differential system on composited wires and the bridging system on simplex and single wires, on the New York Central Lines. However, it is apparent from some oscillograms taken that bridging sets can be speeded up when used on composited circuits by removing the condensers and coils in the Morse legs of the composite sets, but because the efficiency of the differential is higher and the polar relay in it gets more current at lesser operating voltages, it seems preferable to use differential on composited circuits. The lessened voltage results in lessened disturbance in the telephone branch of the circuit.

Oscillograms No. 458 and No. 459 of Fig. 37 show the outgoing and incoming waves on a circuit made up of a 280-mile loop of simplexed telephone lines equipped with Western Electric Company straight step-up selectors, consisting of two so-called "high-resistance" simplexes—one 140-mile No. 8 B. W. G. iron pair, and the other 140-mile No. 9 B. & S. copper pair—connected together without repeaters at the junction point. That is, the circuit was arranged with two duplex sets at Indianapolis, Ind., on two simplexes to Springfield, Ohio, where the simplexes were tied together without repeaters. This permitted simultaneously recording both outgoing and incoming waves at Indianapolis. The sharpness of the differential waves in trace No. 1 of No. 459 is noticeable, compared with the more rounded wave of trace No. 1 of No. 458, which is the bridging duplex. The duplex sets used were standard Western Union instruments, installed according to that company's specifications. The simplex coils were Western Electric Company No. 46-A with No. 34-B non-inductive resistances added between the No. 46-A coil and the line.

A number of records were made to see if a differential set at one end of a line and a bridging set at the other had any effect upon the operation of the circuit, but no detrimental effect could be noted. One point noted was that the received wave is the same shape in both differential and bridging circuits. The sharp peak of the outgoing differential set is absorbed by the line, upon simplex and composites at least, which were the kind of circuits tested. This is illustrated in trace No. 2 of No. 567 of Fig. 35 for bridging set, and No. 568 for differential set, which were taken on a low-resistance phantom composite loop of Fig. 11. These two circuits were 140 miles each, No. 9 A. W. G. copper dispatching and message lines. Points *a* and *b* of Fig. 11 were connected at the Bellefontaine end, making a loop, Indianapolis to Bellefontaine and return. All the composite and telegraph equipment was cut off at Bellefontaine.

The effect of the grounded capacity and half No. 5-AA retard coils in the Morse legs was noted by cutting

them out and taking No. 569 bridging and No. 570 differential, other conditions being the same as Nos. 567 and 568. In Nos. 567 and 568 trace No. 1 is the polar relay current, and trace No. 2 is the line current at the receiving station. In Nos. 568 and 570, No. 1 is the artificial line current and No. 2 the line current at the receiving station. Comparison of Nos. 567 and 569, bridging sets, indicates that the half No. 5-AA coils and six-microfarad condensers, as used in No. 567, appreciably round off the waves and slow up the circuit, and that they can be dispensed with and yet obtain fairly smooth waves as in No. 569. Comparison of Nos. 568 and 570, differential sets, indicates

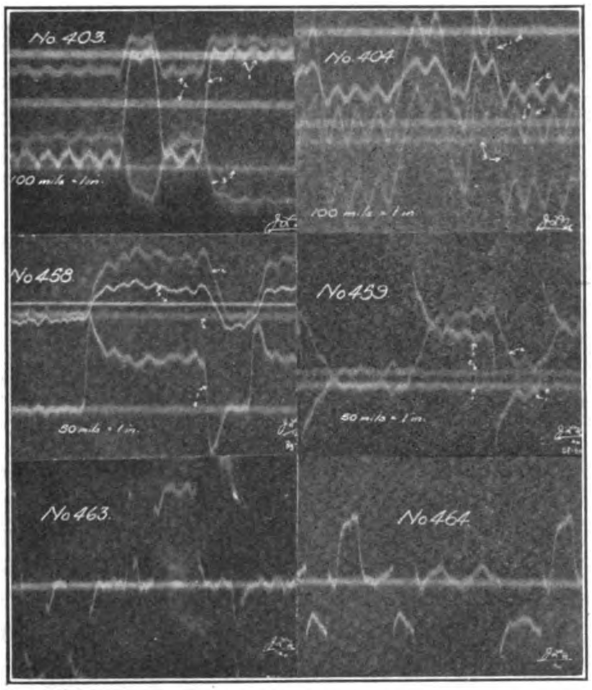

FIG. 37

the necessity of having these coils, as No. 570 has rather sharp waves. No. 568 indicates that the differential waves are rounded out enough to prevent induction.

An interesting exhibit is shown in No. 463 and No. 464, which are records made on two working multiplex printing telegraph circuits. The No. 463 was taken at Indianapolis on a Chicago-Louisville multiplex wire, and No. 464 was at Indianapolis on an Indianapolis-Cincinnati multiplex wire. It is evident that No. 464 was being operated as a differential set, and it is probable that No. 463 was also, but as the record was made at the middle of the line, the waves are somewhat rounded off. No. 464 illustrates why induction is heard on telephone circuits from these multiplex circuits with their sharp waves.

Records No. 403 and No. 404 of Fig. 37 show the result of 25-cycle induction from a single-phase trolley line on duplexes, used on a composite leg of a No. 9 A. W. G. copper, low-resistance phantom, Indianapolis to Cincinnati, 110 miles. The trolley line parallels the railroad from Indianapolis, 40 miles toward Cincinnati. The No. 403 is with duplexes with 500-ohm resistance in place of the No. 5-U coils. Trace No. 1 is line current, trace No. 2 is artificial line and trace No. 3 is the polar relay. The No. 404 is the same as No. 403, but has No. 5-U coils, which greatly amplify the induced waves, but the net operating current in the polar relay is about the same in both. The effect of an induced wave, if it should occur at a time of zero current in the polar relay, might cause false signals, with the No. 5-U coil set.

The investigations indicate that the one-microfarad condenser in duplex and quadruplex sets at the vertex of the No. 5-U retard coil, has but slight bearing on the wave shape of the circuit and is chiefly advantageous as a spark eliminator at the pole-changer contacts. Six microfarads were tried without noticeable effect.

It is noted in the bridging quadruplex that the holding condenser current affects a loop consisting of the condenser, the holding relay, line relay and bridge relay. No effect of it can be detected in the line, the artificial line or in the No. 5-U coil.

The "bulge" of the polar relay current is noted in both the duplex and quadruplex. In the quadruplex this is confined to the above mentioned loop consisting of the holding condenser circuit, line relay and bridge relay. In the duplex it is seen to a limited extent in the line and in the No. 5-U coil.

TELEGRAPH TRANSMISSION DISTANCES

On the N. Y. C. Lines three hundred miles are about the maximum a single No. 8 B. W. G. iron wire is used for single Morse in through service or semi-local service. If all way offices are cut in, the average distance is 150 miles. On iron wire block simplexes the distances are about the same as above. While the line wire resistance is halved in a block simplex, the leakage is increased and the simplex coil resistance is added, resulting in the wire being about as good as a single wire of similar material and gage for the same length. There are so few single copper wires in the N. Y. C. Lines in telegraph use, that no experience with them can be related. As indicated in the discussion of single Morse operation on page 51, these iron wires prove unsatisfactory for local way wires with many offices in wet and foggy weather. Iron wire should not be considered for main lines with heavy traffic because of the rapid deterioration from smoke.

Duplexes are used on the average for about one railroad division which is 150 miles, on high-resistance simplexes of No. 8 B. W. G. iron wire. Copper wire simplexes or composites, No. 9 A. W. G., high-resistance type, are good for more than this length but seldom for two divisions. Low-resistance copper simplexes or composites, No. 9 A. W. G., are good for 300 miles. Copper wire, No. 8 B. W. G., is used in simplex composite and phantom composite, low-resistance type, for 500 miles.

Quadruplexes are good for about 300 miles on single No. 9 A. W. G. copper wire; block simplex, No. 8 B. W. G. iron, for 150 miles; high-resistance No. 8 B. W. G. iron simplexes, 100 miles; copper No. 9 A. W. G. simplexes, high-resistance type, to perhaps 150 miles; and on low-resistance type 200 miles. Very little data regarding quadruplexes on composite circuits are available. This combination is seldom used. The above data are for circuits without repeaters.

Comparison of the telegraph transmission qualities of different gages and kinds of wires and types of circuits have been made and are recorded in Fig. 38. No. 616 is the record of a bridging duplex, first with the distant station sending, which is the trace above the base line, and second with the home station sending, which is the trace below the base line. The wire is a No. 9 A. W. G. copper single wire between Indianapolis and Mattoon, Ill., distance 134 miles. In this territory there is very little cable—hardly enough to

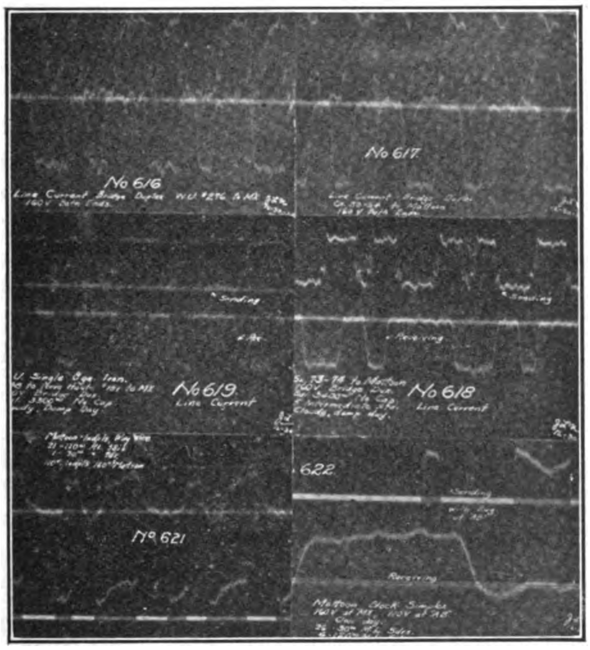

Fig. 38

be considered in such short duplexes. No. 617 is the same duplex on one side of a composited phantom between the same two points and recorded similarly. The circuit is No. 9 A. W. G. copper, low-resistance type simplex on the dispatcher's circuit, which is one side of a phantom. It will be seen that the current is greater on this than on the single copper wire and the wave shape is practically the same, indicating that the circuit is about as fast in dry weather as the single wire.

The duplexes were next moved to the No. 8 B. W. G. iron wire between the same points with the result given in No. 619. No. 618 is the result on a No. 8 B. W. G. iron wire simplex circuit between these points, low-resistance type, and indicates as good a dry-weather cuit as the single iron wire No. 619.

cirFig. 18 gave the record of the way Morse wire on this division of the railroad, taken at the time when it was equipped with 120-ohm main line sounders. This wire was later made one side of the station-to-station block telephone circuit and simplexed for the way-station Morse service, at which time it was equipped with 30-ohm main line sounders. The record of its present transmission is No. 622. The Western Union way wire in this territory is No. 8 B. W. G. iron, with 120-ohm main line sounders, and is recorded in No. 621. The block simplex has more current but has 30 offices, whereas the W. U. Co. way wire has but 22 offices.

Telephone Transmission Distances

Experience indicates that the railroad service requires ten-mile telephone transmission or better for the dispatching, message and long-distance lines. Dissatisfaction results if the equivalent in miles of standard cable is much greater than this. This shows that the railroad demands better transmission than is considered satisfactory in commercial service. From the standpoint of practical results and satisfaction to the users of the railroad telephone lines the following has been noted:

No. 8 B. W. G. iron for long-distance lines should not exceed 50 miles of line; for way-station message telephone lines using railroad telephones, 75 miles.

No. 9 A. W. G. copper for long-distance lines should not exceed 150 miles; for dispatching and message lines, 225 miles; for phantoms composited, 150 miles.

No. 8 B. W. G. copper for long-distance lines should not exceed 300 miles without repeaters.

The above figures are based upon average conditions such as obtain upon the New York Central Lines, and take into consideration that some of the P. B. X. stations are a considerable distance from the P. B. X. which limits the transmission distance because of the loop losses. Circuits are frequently used of longer distances than the above but at a sacrifice in efficiency and with some annoyance to the users.

The railroad telephones as used on dispatching and message lines produce considerably more volume of transmission than standard P. B. X. station telephones, and therefore have greater transmission distance, which experience indicates is 30 per cent greater than the standard P. B. X. stations for equal volume of received transmission.

The author wishes to express his cordial appreciation of the extensive assistance rendered by Mr. John L. Niesse, Telegraph & Telephone Engineer, C. C. C. & St. L. Ry., in making the oscillograms and for other assistance in preparing data for this paper, and to Professor C. Francis Harding, Head, School of Elec. Eng., Purdue University, for the use of the oscillograph.

Heat Losses in the Conductors[1] of Alternating-Current Machines

BY WALDO V. LYON
Massachusetts Institute of Technology

WITH the increase in the capacity of alternating-current generators, it has become more and more important to determine the exact relation between the heat developed in any conductor and the currents that it and other neighboring conductors carry. Solutions for the distribution of alternating current within conductors that are embedded in open rectangular slots have been obtained for a number of cases. The methods of attack and the results obtained have heretofore involved trigonometric and hyperbolic functions of real angles. For this reason the work has been unnecessarily complicated, and its scope considerably cramped. Had the investigators used hyperbolic functions of *complex* angles, they would have accomplished more with much less effort. These hyperbolic functions of *complex* angles are such a powerful tool in the solution of this current distribution problem that the author feels fully justified in presenting this discussion of their application, even though many of the results have been obtained before.

At the outset it should be observed that certain assumed ideal conditions are necessary in order to bring the problem within the range of our mathematical ability.[2] Briefly these conditions are (1) that an element of current in the slot produces a uniform parallel magnetic field above itself and none below it; (2) that the current density along any line parallel to the bottom of the slot is constant; (3) that the resistivity of the conductor is uniform throughout, even though more heat is developed in some portions than in others; (4) that voltages in the end connections due to leakage flux are the same for every element of the conductor.

1. The first assumption can be shown to be exactly true in the hypothetical case of an infinitely long rectangular conductor placed in an infinitely deep rectangular slot of the same width which is cut into an infinite medium of infinite permeability.

2. The second assumption is probably sufficiently accurate, except when conductors that carry different currents are placed side by side in the same slot, a condition which we will not consider.

3. The heat conductivity of copper is so high that the temperature of any one conductor is probably nearly uniform, except in the case of extremely deep conductors, and the resistivity would thus not vary appreciably from point to point. In the case of multiple layer coils, however, there may be such a difference in the amount of heat developed in successive layers that it may be desirable to use different resistivities for different layers. In order to carry out this refinement in the calculations, a considerable practical knowledge of the principles of heat radiation in this problem would be necessary, and the final result would probably be obtained by making successive approximations.

4. The leakage flux about the end connections is of course much less than that about the embedded portion of the coils, and is distributed in a totally different manner. Any rational consideration of the effect of this flux would lead to considerable complication in the mathematical analysis. Thus for the sake of simplicity—a feeble reason, no doubt—it is not considered. It is probable, however, that in a great many instances this coil-end leakage is of relatively minor importance.

The best test of the value of the mathematical deductions based on the foregoing assumptions lies in experimental research. The little evidence that we now have seems to confirm the theory within reasonable limits of error, and it is hoped that a more extended investigation, which is being carried on, will prove conclusive.

To the author, it seems nearer the physical reality to say that the increased heat loss in a conductor carrying alternating rather than direct current is caused by a redistribution of current over the cross-

1. An abstract of this paper was presented before the Research Division of the Electrical Engineering Department at the Massachusetts Institute of Technology, April 13, 1920. The author's attention was first directed to this method of analysis by Dr. A. E. Kennelly to whom great credit is due especially on account of the extensive tables he has published from which numerical computations may readily be made: "Tables of Complex Hyperbolic and Circular Functions," A. E. Kennelly.

"Eddy Currents in Large Slot-Wound Conductors," A. B. Field, Annual Convention, A. I. E. E., 1905.

"Current Distribution in Armature Conductors," W. V. Lyon, *Electrical World*, July 12, 1919.

Since this present analysis was made, Mr. R. E. Gilman has presented at the Annual Convention, A. I. E. E., 1920, a paper entitled "Eddy Current Losses in Armature Conductors." This paper of Mr. Gilman's, although he uses real quantities exclusively, is more complete in one respect than the one here presented in that he considers the case of a laminated conductor with a finite number of strands.

2. Both A. B. Field and R. E. Gilman assume these ideal conditions in the derivation of their formulas.

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

section of the conductor.[3] This redistribution is due to the electromotive forces set up by the magnetic flux *within* the conductor itself. Flux that is wholly without the conductor links all elements of it equally, produces the same voltage in each element, and thus does not affect the current distribution.

Consider any conductor lying in the midst of others, as shown in cross-section in Fig. A. Further, consider any element of this conductor of depth $d\,x$ situated x centimeters from the bottom of the conductor. With a solid conductor the length of this element should be taken only as the length of the armature core. The allowance that need be made for ventilating ducts, and more particularly for end turns, can only be determined by. considerable experimental research. With finely laminated conductors, the current density is constrained to be the same in, at least, the length of a half turn, and the length of the element is then that of a half turn.

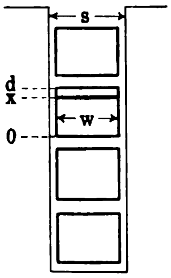

FIG. A

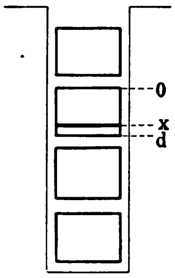

FIG. B

The net voltage acting on the element is the sum of the resistance drop and the voltage drop due to flux linkages. The former is $l_1\,\rho\,c$; where l_1 is the length of the core with solid conductors, or a half turn with finely laminated ones, ρ is the resistivity and c is the current density—all in c. g. s. units. The voltage drop due to flux linkages may be divided into two parts; that due to flux set up by the current in the conductor itself, and that due to flux set up by current in other conductors in the slot *below* the one we are considering. Any current above this conductor produces flux that links all elements of it *alike*, and induces the *same* voltage in each. The manner in which a *given* current is distributed in any conductor below the one in question does not affect the amount of flux linking the element considered. Furthermore any flux due to these latter currents that passes across the slot above the conductor we are considering links all of its elements alike, and, since it produces the same voltage in each, need not be considered. Thus the total flux linking the element in question that need be taken into account is:

$$\varphi = 4\,\pi\,i_b\,\frac{d-x}{s}\,l_2 + \int_x^d \left\{ 4\,\pi \int_0^x w\,c\,\partial\,x \right\} \frac{l_2\,\partial\,x}{s}$$

The first term is the flux, linking the element due to a total current of i_b below the conductor of which the element is a part. The second term is the flux from x to d due to the current within the conductor itself from zero to x. l_2 is the length of the armature core, s is the width of the slot, and w that of the conductor.

The total voltage drop that need be considered is:

$$e = l_1\,\rho\,c + \frac{\partial}{\partial\,t} \left\{ 4\,\pi\,i_b\,\frac{d-x}{s}\,l_2 + \int_x^d \left\{ 4\,\pi \int_0^x w\,c\,\partial\,x \right\} \frac{l_2\,\partial\,x}{s} \right\} \qquad \textbf{(A)}$$

In a solid conductor this voltage drop is the same for every element, and $\frac{\partial\,e}{\partial\,x}$ will thus be zero. Also l_1 and l_2 are equal. Differentiating e and dividing by l_2 gives:

$$\rho\,\frac{\partial\,c}{\partial\,x} - \frac{4\,\pi}{s}\,\frac{\partial\,i_b}{\partial\,t} - \frac{4\,\pi}{s} \int_0^x w\,\frac{\partial\,c}{\partial\,t}\,\partial\,x = 0 \qquad \textbf{(B)}$$

With finely laminated conductors whose laminations are joined at the beginning and end of each half turn, the same result is obtained except that l_1 and l_2 are not equal. Then:

$$\frac{l_1}{l_2}\,\rho\,\frac{\partial\,c}{\partial\,x} - \frac{4\,\pi}{s}\,\frac{\partial\,i_b}{\partial\,t} - \frac{4\,\pi}{s} \int_0^x w\,\frac{\partial\,c}{\partial\,t}\,\partial\,x = 0$$

With finely laminated conductors whose end turns are untwisted and in which the laminations are continuous throughout a whole turn or a whole coil, the voltage in a half turn of any element is as given above. (Equation **A**). The sum of these half-turn voltages between the points at which the laminations are joined together must be the same for each lamination. This sum will consist of a number, n, of resistance drops, and an equal number of voltage drops due to flux linkages. The resultant drop is

$$e = n\,l_1\,\rho\,c + \frac{\partial}{\partial\,t} \sum_1^n 4\,\pi\,i_b\,\frac{d-x}{s}\,l_2$$

$$+ n\,\frac{\partial}{\partial t} \int^d \left\{ 4\,\pi \int_0^x w\,c\,\partial\,x \right\} \frac{l_2\,d\,x}{s} = 0$$

The current i_b, below the conductor of which the half-turn element is a part, is not the same for the different half-turn elements. Nevertheless, it is a simple matter to compute the average value of this quantity, *viz.*, $1/n \sum_1^n i_b$ for any arrangement of conductors. It is, of course, not necessary that the component i_b's should be in phase with each other. This computation is subsequently shown in detail. We will represent this average value of i_b by i_0. If the entire voltage for this element be divided by $n\,l_2$ and then differentiated with respect to x, we have:

$$\frac{l_1}{l_2}\,\rho\,\frac{\partial\,c}{\partial\,x} - \frac{4\,\pi}{s}\,\frac{\partial\,i_0}{\partial\,t} - \frac{4\,\pi}{s} \int_0^x w\,\frac{\partial\,c}{\partial\,t}\,\partial\,x = 0$$

3. Others prefer to say that the increased heating is due to the eddy currents produced by the magnetic flux within the conductor. Either description is permissible.

In the case of finely laminated conductors that are twisted in the end connections so that the top lamination of one half turn becomes the bottom lamination of the next half turn, a similar equation may be derived. When the end turn is twisted in passing from one coil side to the next, the flux within the conductor linking the half-turn element of one side has already been given. (Equation **A**). The flux linking the next half turn of this element is, (Fig. B):

$$\rho = 4\,\pi\, i_b \frac{x\, l_2}{s} + \int_0^x \left\{ 4\,\pi \int_x^d w\, c\, \partial x \right\} \frac{l_2\, \partial x}{s}$$

The first term is the flux from zero to x due to a current of i_b below this conductor. The second term is the flux from zero to x due to current from x to d within the conductor itself. The second term may be rewritten in this way:

$$\int_0^x 4\,\pi \left\{ \int_0^d w\, c\, \partial x - \int_0^x w\, c\, \partial x \right\} \frac{l_2\, \partial x}{s}$$

The voltage drop in this half-turn element becomes:

$$e = l_1\, \rho\, c + \frac{\partial}{\partial t} \left\{ 4\,\pi\, i_b \frac{x\, l_2}{s} + \int_0^x 4\,\pi \int_0^d w\, c\, \partial x \,.\, \frac{l_2 \partial x}{s} - \int_0^x 4\,\pi \int_0^x w\, c\, \partial x \,.\, \frac{l_2\, \partial x}{s} \right.$$

$\int_0^d w\, c\, \partial x$ is the entire current in the conductor of which the element is a part. Represent this current by i. Differentiate e with respect to x and divide by l_2. We have:

$$\frac{l_1}{l_2}\, \rho\, c + \frac{4\,\pi}{s} \frac{\partial\, i_b}{\partial\, t} + \frac{4\,\pi}{s} \frac{\partial\, i}{\partial\, t} - \frac{4\,\pi}{s} \int_0^x w \frac{\partial\, c}{\partial\, t}\, \partial\, x = 0 \qquad \textbf{(C)}$$

Thus in every case that we shall discuss, the following equation may be written:

$$\rho \frac{\partial\, c}{\partial\, x} - \frac{\partial}{\partial\, t} \frac{4\,\pi\, i_0}{s} - \frac{i\, \partial}{\partial\, t} \frac{4\,\pi}{s} \int_0^x w\, c\, \partial\, x = 0 \;[4]$$

ρ is the resistivity in the case of solid conductors, and is the resistivity multiplied by the ratio of the length of a half turn to the length of the core in the case of infinitely laminated conductors. c is the instantaneous current density in amperes per square centimeter along a line x centimeters from the bottom of the conductor. s is the width of the slot and w, that of the conductor. The first term is the differential of the resistance drop per centimeter in any element. The second term is the differential of the voltage per centimeter due to the flux produced by other currents in the same slot. As we shall see, i_0 is determined by the arrangement of the conductors and the currents they carry. The third term is the differential of the voltage per centimeter due to the flux produced by current within the conductor itself below the element considered. If the currents vary sinusoidally with the time, the differential operator $\frac{\partial}{\partial\, t}\cdot$ may be symbolically represented by $j\, \omega$; $j = \sqrt{-1}$, $\omega = 2\,\pi\, f$ where f = frequency.

The equation may now be written in the complex or vector form:

$$\frac{\partial\, \underset{\cdot}{c}}{\partial\, x} - j \frac{4\,\pi\, \omega}{\rho\, s}\, I_0 - j \frac{4\,\pi\, \omega}{\rho\, s} \int_0^x w\, \underset{\cdot}{c}\, \partial\, x = 0 \qquad \textbf{(1)}$$

Differentiating a second time gives:

$$\frac{\partial^2\, \underset{\cdot}{c}}{\partial\, x^2} = j \frac{4\,\pi\, \omega}{\rho\, s}\, w\, \underset{\cdot}{c}$$

or:

$$\frac{\partial^2\, \underset{\cdot}{c}}{\partial\, x^2} = \alpha^2\, \underset{\cdot}{c} \qquad \textbf{(2)}$$

where

$$\left.\begin{aligned} \alpha^2 &= j \frac{8\,\pi^2\, w\, f}{\rho\, s} \\ \text{or} \quad \alpha &= \sqrt{\frac{8\,\pi\, w\, f}{\rho\, s}} \;\underline{/45^\circ} \end{aligned}\right\}$$

The solution of equation (**2**) may be written in the form

$$\underset{\cdot}{c} = \underset{\cdot}{A} \cosh \alpha\, x + \underset{\cdot}{B} \sinh \alpha\, x \qquad \textbf{(3)}$$

This is a vector equation for the root-mean-square current density at a point x centimeters from the bottom of the conductor. The constants of integration $\underset{\cdot}{A}$ and $\underset{\cdot}{B}$ are vector quantities and are usually determined by the current in the conductor considered and by the vector I_0 in equation (**1**). Substitution of equation (**3**) in equation (**1**) shows that:

$$\underset{\cdot}{B} = \alpha / w\, I_0$$

If the depth of the conductor is d centimeters, the current in it is

$$I_1 = \int_0^d w\, \underset{\cdot}{c}\, \partial\, x$$

from which it follows that:

$$\underset{\cdot}{A} = \frac{\alpha}{w} \left\{ \frac{I_1}{\sinh \alpha\, d} - I_0 \tanh \frac{\alpha\, d}{2} \right\}$$

Therefore, the general solution for the vector current density may be written:

4. An equation of this sort applies only to the conductor in which the current density is a continuous function with respect to x, such as is the case with solid or finely laminadet conductors. When the laminations have appreciable depth the current density changes abruptly as we pass from one lamination to the next. The effect of this is that the vector constant i_0 is different in successive laminations. A comparison of equations (**B**) and (**C**) shows that twisting the end connections reverses the effect of the current, i_b, below the conductor we are considering.

$$c = \frac{1}{w\,d}\left\{\frac{I_1\,\alpha\,d\cosh\alpha\,x}{\sinh\alpha\,d} - I_0\,\alpha\,d\tanh\frac{\alpha\,d}{2}\cosh\alpha\,x + I_0\,\alpha\,d\sinh\alpha\,d\right\} \qquad (4)$$

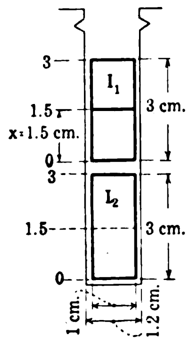

FIG. 1

A numerical calculation is helpful. Consider the case of two solid rectangular conductors situated as shown in Fig. 1. The 60-cycle currents are each 1000 amperes but the lower current leads the upper by 60 degrees as would be the case in some of the slots of a three-phase fractional pitch winding. As we shall presently see $I_0 = I_2$ in this case.

ρ = 2100 c. g. s. units of resistance
w = 1 cm.
s = 1.2 cm.
d = 3 cm.
f = 60 cycles

$$\alpha\,d = 3\sqrt{\frac{8\,\pi^2 \times 1 \times 60}{2100 \times 1.2}}\ \underline{/45^\circ}$$
$$= 4.11\ \underline{/45^\circ}$$

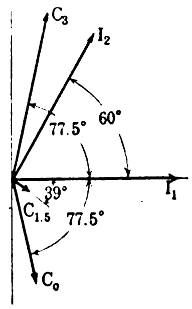

FIG. 2—CURRENT DENSITIES IN UPPER CONDUCTOR

Referred to I_1 the current densities are:

$C_0 = 1620\ \underline{/-77.^\circ 5}\ \dfrac{\text{amperes}}{\text{sq. cm.}}\ \underline{/\quad}$

$C_{1.5} = 305\ \underline{/-39.^\circ}\ \dfrac{\text{amperes}}{\text{sq. cm.}}\ \underline{/\quad}$

$C_3 = 2490\ \underline{/77.^\circ 5}\ \dfrac{\text{amperes}}{\text{sq. cm.}}\ /$

$$\alpha\,x = 2.06\ \underline{/45^\circ}$$
$$\sinh\alpha\,d = 9.12\ \underline{/166.^\circ 4}$$
$$\tanh\frac{\alpha\,d}{2} = 1.11\ \underline{/1^\circ.41}$$
$$\sinh\alpha\,x = 2.24\ \underline{/84.^\circ 1}$$
$$\cosh\alpha\,x = 2.03\ \underline{/82.^\circ 7}$$

If we choose I_1 along the horizontal, *i. e.*, with zero phase:

$$I_1 = 1000\ \underline{/0^\circ}\ ,\ I_0 = 1000\ \underline{/60^\circ}$$

$$c_{1.5} = \frac{1}{1 \times 3}\Big\{(1000\ \underline{/0^\circ} \times 4.11\ \underline{/45^\circ} \times 2.03\ \underline{/82.^\circ 4} \div 9.12\ \underline{/166.^\circ 4}) - (1000\ \underline{/60^\circ} \times 4.11\ \underline{/45^\circ} \times 1.11\ \underline{/1.^\circ 41} \times 2.03\ \underline{/82.^\circ 7}) + (1000\ \underline{/60^\circ} \times 4.11\ \underline{/45^\circ} \times 2.24\ \underline{/84.^\circ 1})\Big\} = \frac{1}{1 \times 3}\Big\{915\ \underline{/-39.^\circ 0} - 923\ \underline{/189.^\circ 1} + 923\ \underline{/189.^\circ 1}\Big\}$$

$$c_{1.5} = 305\ \underline{/-39.^\circ 0}$$
$$c_0 = 1620\ \underline{/-77.^\circ 5}\ .$$
$$c_3 = 2490\ \underline{/77.^\circ 5}$$

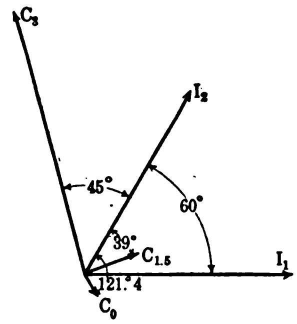

FIG. 2A—CURRENT DENSITIES IN LOWER CONDUCTOR

Referred to I_2 the current densities are:

$C_0 = 150\ \underline{/-121.^\circ 4}\ \dfrac{\text{amperes}}{\text{sq. cm.}}\ \underline{/\quad}$

$C_{1.5} = 305\ \underline{/39^\circ}\ \dfrac{\text{amperes}}{\text{sq. cm.}}\ \underline{/\quad}$

$C_3 = 1380\ \underline{/45^\circ}\ \dfrac{\text{amperes}}{\text{sq. cm.}}\ /$

Fig. 2 is the vector diagram showing the current densities at the bottom, middle and top of the conductor, together with the total current in it, I_1, and the current below it, I_2.

The current density at the center, where $\alpha\,x$ equals $\dfrac{\alpha\,d}{2}$, is:

$$c = \frac{I_1}{w\,d}\ \frac{\dfrac{\alpha\,d}{2}}{\sinh\dfrac{\alpha\,d}{2}}$$

It depends only upon the average current density and the angular depth, $\alpha\,d$, and is in no way affected by the position of the conductor in the slot. It is the same for solid and finely laminated conductors.

The current density is nowhere greater than at the top of the conductor, where it is:

$$\varrho_d = \frac{1}{w\,d}\left\{ I_1\,\alpha\,d \coth\alpha\,d + \frac{I_0}{2}\,\alpha\,d\,2\tanh\frac{\alpha\,d}{2}\right\} \tag{5}$$

The ratio of this maximum current density to the average is:

$$\frac{\varrho_d}{\varrho_{av}} = \alpha\,d\coth\alpha\,d + \frac{I_0}{2\,I_1}\,\alpha\,d\,2\tanh\frac{\alpha\,d}{2} \tag{6}$$

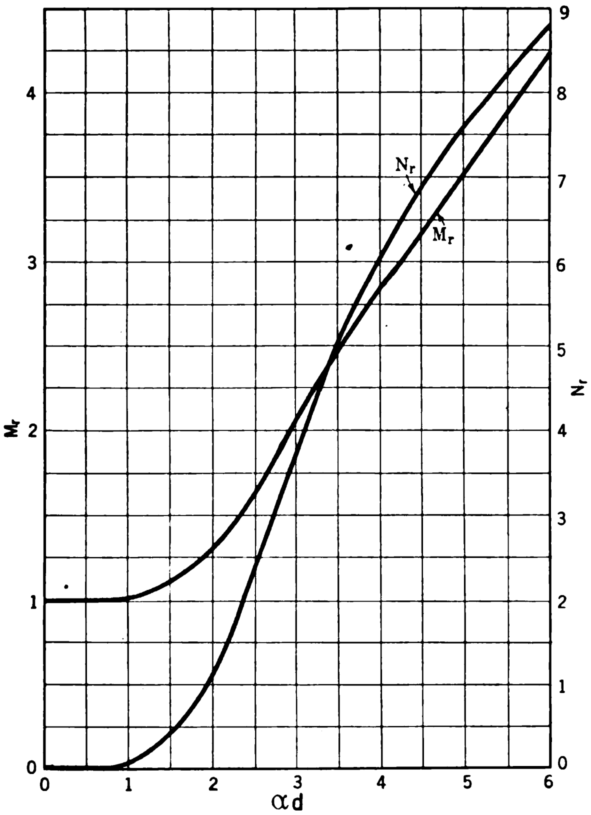

FIG. 3

The complex quantities $\alpha\,d\coth\alpha\,d$ and $\alpha\,d\,2\tanh\frac{\alpha\,d}{2}$ occur in all of the expressions which we shall develop, and thus it will be simpler to represent them by single letters. Hereafter

$$\alpha\,d\coth\alpha\,d = M = M_r + j\,M_x$$

$$\alpha\,d\,2\tanh\frac{\alpha\,d}{2} = N = N_r + j\,N_x$$

In Figs. 3 and 4 the abscissas are the numerical values of $\alpha\,d$ and the ordinates are M_r, M_x, N_r, N_x. The real portions of M and N, *viz.*, M_r and N_r, appear in the expressions for resistance, and the imaginary portions, M_x and N_x, in the expressions for reactance.

The voltage drop per centimeter in the conductor considered due to its own resistance and to all of the leakage flux below its topmost layer is:

$$\rho\,\varrho_d = \frac{\rho}{w\,d}\left\{ I_1\,M + \frac{I_0}{2}\,N\right\} \tag{7}$$

The flux within the conductor due to its own current and all of the current, I_b, below it is:

$$\varphi = \int_0^d \partial x \frac{4\,\pi}{s}\int_0^x w\,\varrho\,\partial x + \frac{4\,\pi\,d}{s}\,I_b$$

On integration the expression for the flux may be written:

$$\varphi = \frac{1}{j\,\omega}\,\frac{\rho}{w\,d}\left\{\left(\frac{I_1}{2} + I_0\right)N + (I_b - I_0)\,\alpha^2\,d^2\right\}$$

The voltage drop per centimeter produced by this flux in each conductor below the one considered is $j\,\omega\,\varphi$, which may now be written:

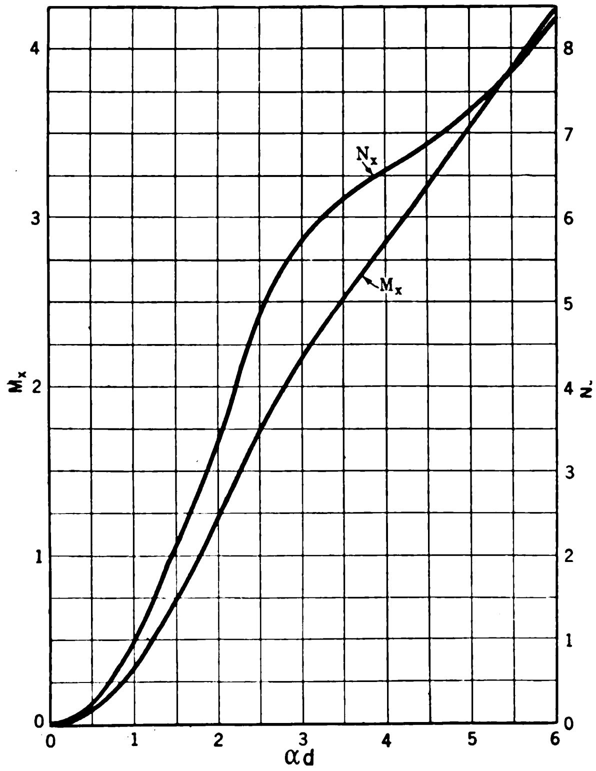

FIG. 4

$$E = \frac{\rho}{w\,d}\left\{\left(\frac{I_1}{2} + I_0\right)N + (I_b - I_0)\,\alpha^2\,d^2\right\} \tag{8}$$

The relations expressed in equations (7) and (8) are very important since their proper combination will give the leakage impedance drop due to resistance and leakage flux within the conductors themselves for any arrangement of solid or infinitely laminated conductors. The reactance due to slot-leakage flux which does not pass through the conductors can be calculated by well-known methods and need not be considered here.

If the equations (7) and (8) are each multiplied by

the length of the core, l, they will apply to the embedded portion of a solid conductor, the true resistance of which is R, and to the half turn of an infinitely laminated one, the true resistance of which is also R. Thus (**7**) and (**8**) may be written:

$$l \rho \, \dot{c}_d = R \left\{ I_1 M + \frac{I_0}{2} N \right\} \qquad \textbf{(7a)}$$

$$l E \quad = R \left\{ \left(\frac{I_1}{2} + I_0 \right) N + (I_b - I_0) \, \alpha^2 d^2 \right\} \qquad \textbf{(8a)}$$

The *additional* voltage produced in all conductors below the one in question by flux within it due to its own current is

$$l E' \quad = R \left\{ \left(\frac{I_1}{2} + I_0 \right) N - I_0 \, \alpha^2 d^2 \right\} \qquad \textbf{(8b)}$$

Having found the vector impedance drop in the conductors of one phase by properly applying equations (**7a**) and (**8a**), the effective resistance and reactance of that phase are determined by dividing this drop by the vector current. The real portion of the result is the effective resistance and the imaginary portion, the effective reactance. This method, however, gives no indication of the distribution of the copper loss among the several conductors of the phase. This may be of considerable importance, especially in the case of solid conductors when the heat developed in the topmost conductor in a slot may be several times that developed in the bottom conductor.

The current through a conductor is non-uniformly distributed on account of flux *within* the conductor. This flux is due only to the current in the conductor itself and to current below it in the slot. Any current above the conductor in question has no effect on the current distribution within it. The heat generated within a conductor depends only upon the manner in which the current is distributed. The current density is completely determined by equation (**1**) and the total current in the conductor itself. For any particular value of I_0 (equation **1**) the heat developed by a given current in the conductor does not depend upon whether I_0 is some particular current or some combination of currents. Thus if it is possible to find the heat loss when I_0 is some particular current, we will have obtained a general expression for the loss in terms of the current in the conductor, I_1, and the constant, I_0, in equation (**1**). The particular case which we will consider is that of a solid conductor carrying a current of I_1 with a total current of I_b below it. The special form of equation (**1**) is then,

$$\frac{\partial \dot{c}}{\partial x} - j \, \frac{4 \pi \omega}{\rho s} I_b - j \, \frac{4 \pi \omega}{\rho s} \int_0^x w \, \dot{c} \, \partial x = 0 \qquad \textbf{(1a)}$$

Thus for this arrangement, $I_0 = I_b$.

The heat loss in the conductor is equal to the total power supplied both to this conductor and to all of those below it less the power supplied to those below it when the conductor is removed from the slot. The addition of the conductor in question increases the power supplied to the lower conductors without increasing the heat loss in them on account of its mutual inductive effect upon them *i. e.*, as some would say, on account of the eddy currents which are produced in it by the total current I_b, below it. The power supplied to the upper conductor is, symbolically, since $I_0 = I_b$

$$I_1 R \left\{ I_1 M + \frac{I_b}{2} N \right\} \qquad \textbf{(See 7a)}$$

This indicates the product of the numerical values of the current, I_1, the voltage applied to the conductor and the cosine of the phase angle between them. Flux above the conductor produces a quadrature voltage and thus does not affect the power. The *additional* power supplied to the conductors below this one is symbolically

$$I_b R \left\{ \left(\frac{I_1}{2} + I_b \right) N - I_b \, \alpha^2 d^2 \right\} \qquad \textbf{(See 8b)}$$

The actual heat loss in the conductor is thus symbolically:

$$I_1 R \left\{ I_1 M + \frac{I_b}{2} N \right\} + I_b R \left\{ \left(\frac{I_1}{2} + I_b \right) N - I_b \, \alpha^2 d^2 \right\}$$

This reduces to:

$$R \left\{ I_1^2 M_r + (I_b^2 + I_1 I_b \cos \theta) N_r \right\} \text{[5]} \qquad \textbf{(9a)}$$

where I_1 and I_b are the numerical values of the currents and θ is the phase angle between them. Therefore the general expression for the heat loss in any conductor, solid or infinitely laminated, is:

$$R \left\{ I_1 M_r + (I_0^2 + I_1 I_0 \cos \theta) N_r \right\} \qquad \textbf{(9)}$$

where I_1 is the numerical value of the current in the conductor, I_0 is the numerical value of the vector constant in the differential equation (**1**), and θ is the phase angle between I_1 and I_0. The ratio of alternating-current to direct-current resistance is thus:

$$K = M_r + \left(\left| \frac{I_0}{I_1} \right|^2 + \left| \frac{I_0}{I_1} \right| \cos \theta \right) N_r \qquad \textbf{(10)}$$

The vertical lines | | indicate that the division is one of numerical values and not of vector values. The first term M_r accounts for the natural non-uniformity of current distribution due to the action of the current upon itself. The second term

$$\left(\left| \frac{I_0}{I_1} \right|^2 + \left| \frac{I_0}{I_1} \right| \cos \theta \right) N_r,$$

accounts for the additional heating produced by the "eddy currents" due to the action of I_0.

5. M_r and N_r are calculated from the data pertaining to the conductor in question and bear no relation to other conductors.

This equation (**10**) enables us to compute the ratio of alternating-current to direct-current resistance for any conductor carrying a specified current and for which a differential equation of the form given equation (**1**) can be written. In the case of solid conductors, the ratio only applies to the embedded portion. The following are the resistance ratios for some of the simpler arrangements of conductors.

1. The heat loss in an open-circuited bar with I_b amperes below it is:

$$\text{heat loss} = R\, I_b^2\, N_r \qquad (\text{equation } \mathbf{9a},\ I_1 = 0)$$

2. The resistance ratio for the pth conductor of a one-coil-side-per-slot bar winding is:

$$K = M_r + [\,(p-1)^2 + (p-1)]\, N_r$$
$$= M_r + (p^2 - p)\, N_r$$

3. The resistance ratio for a one-coil-side-per-slot winding having n layers is:

$$K = 1/n \sum_1^n \ [M_r + (p^2 - p)\, N_r]$$
$$= M_r + \frac{n^2 - 1}{3}\, N_r$$

This is also the ratio for the lower coil side of any bar winding having n layers. The upper coil side has no effect on the resistance of the lower coil side.

4. The resistance ratio for the upper coil side of a two-coil-side-per-slot fractional pitch winding having n layers per coil side reduces to:

$$K = M_r + \left(\frac{4\, n^2 - 1}{3} + n^2 \cos\theta \right) N_r$$

θ is the phase angle between the currents in the upper and lower coil sides.

By combining this with the ratio just preceding, we obtain the resistance ratio for a coil, one side of which is above a coil side carrying a current which differs in phase by θ.

The hottest conductor is the one at the top of the coil side which has beneath it current of the same phase. The fact that, with solid bar windings, the heat developed is not uniformly distributed throughout the winding may be no inconsiderable argument against their use.

5. Our method of attack enables us to obtain a simple solution for the relation between the currents in a double squirrel-cage winding. Neglect the effect of the end rings. In this case the constant of integration, A, in equation (**3**) is determined by the fact that the resistance drop in the lowest element of the upper bar is the same as the impedance drop in the lower bar due to its resistance and to all of the leakage flux which does not link any portion of the upper bar. The vector equation for the current density in the upper bar may be written:

$$\dot{c} = \frac{I_2\, \dot{Z}_2}{\rho} \cosh \alpha\, x + \frac{I_2\, R_1}{\rho}\, \alpha\, d \sinh \alpha\, x$$

$I_2\, \dot{Z}_2$ is the vector impedance drop in the lower bar per centimeter;[6] ρ and R_1 are respectively the resistivity and the true resistance per centimeter of the upper bar whose depth is d centimeters. α is calculated for the upper bar.

The vector current in the upper bar is:

$$I_1 = \frac{I_2\, \dot{Z}_2}{R_1}\ \frac{\sinh \alpha\, d}{\alpha\, d} + I_2 \cosh \alpha\, d - I_2$$

The process of calculating the heat loss in the upper bar by substitution in equation (**9a**) is much simplified if we let

$$P = \frac{m\, Z_2}{R_1} \cos(\theta_2 + \beta) + n \cos \delta$$

and

$$Q = \frac{m\, Z_2}{R_1} \sin(\theta_2 + \beta) + \sin \delta$$

where:

$$\dot{Z}_2 = Z_2 \,/\underline{\theta_2}\,; \quad \frac{\sinh \alpha\, d}{\alpha\, d}{}^{7} = m \,/\underline{\beta}\,;$$
$$\cosh \alpha\, d = n \,/\delta$$

The expression for the loss in the upper bar is:

$$I_2^2\, R_1\, \{\, [(P-1)^2 + Q^2\,]\, M_r + P\, N_r\, \}$$

This method of solution for the relation between the currents in a double squirrel cage should prove of considerable value in any analysis of the design of such windings.

Finely laminated windings may be of three types: Those in which the laminations are joined at the ends of each half turn; those in which they are joined at the ends of each turn; and those in which the laminations are continuous throughout a single coil. The first is like a solid bar winding except that, as noted previously, the real resistivity of the copper should be multiplied by the ratio of the length of the half turn to the length of the core. The resistance ratio then applies to the whole winding and not to the embedded portion solely. The resistance ratios for the second type depend upon whether the end turn between the coil sides is untwisted or twisted. The resistance ratio for the third type depends upon whether the end turns are untwisted, twisted on one side only, or twisted on both sides. One considerable advantage of continuous laminations is that the heat developed is the same in all of the conductors.

6. Type two: End turn untwisted. The arrangement of the coil sides is shown in Fig. 5. The heavy line across the conductors indicates the same lamination. The current, I_2, below the upper coil side may be in phase with the current above it or differ from it by 60 or 90 degrees. The differential equation of the

6. $I_2\, Z_2$ is the voltage drop due to resistance and flux that does not link the upper bar.

7. See Table IV, Tables of Complex Hyperbolic and Circular Functions.

form (1) applying to this case for the pth layer from the bottom is:

$$2\,\rho\,\frac{\partial ç}{\partial x} - j\,\frac{4\,\pi\,\omega}{s}\,\left\{\,2\,(p-1)\,I_1 + I_2\,\right\}$$
$$-\,j\,\frac{4\,\pi\,\omega}{s}\;2\int_0^x w\,ç\,\partial x = 0$$

Comparing this equation (1) shows that the vector constant I_0 equals $(p-1)\,I_1 + \frac{I_2}{2}$; $I_2 = n\,I_1\,\underline{/\theta}$,

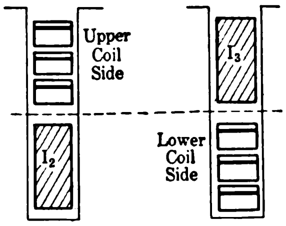

FIG. 5

n is the number of layers in the coil side and θ the phase angle between the currents in the upper and lower coil sides.

Making this substitution, equation (9) reduces to:

Heat loss $= R\,I_1^2\,\{\,M_r + [p^2 - p + n\,(p - 1/2)\cos\theta + n^2/4]\,N_r\,\}$

The resistance ratio for the entire coil is one-nth of the summation of this expression from $p = 1$ to $p = n$. It reduces to:

$$K = M_r + \left(\frac{7\,n^2 - 4}{12} + \frac{n^2}{2}\cos\theta\right) N_r$$

7. Type three: End turns untwisted. In this case the heat developed is the same in each conductor. The differential equation now becomes:

$$2\,n\,\rho\,\frac{\partial ç}{\partial x} - j\,\frac{4\,\pi\,\omega}{s}\sum_1^n \{2\,(p-1)\,I_1 + I_2\,\}$$
$$-\,j\,\frac{4\,\pi\,\omega}{s}\;2\,n\int_0^x w\,ç\,\partial x = 0$$

In this case $I_0 = \frac{n-1}{2}\,I_1 + I_2$. Making this substitution in equation (10) gives the resistance ratio for the whole coil.

$$K = M_r + \left(2\,\frac{n^2 - 1}{4} + \frac{n^2}{2}\cos\theta\right) N_r$$

8. Type two: End turns twisted. When the end turns are twisted on one side only the top laminations in one coil side become the bottom laminations of the other coil side in corresponding layers. See Fig. 6. The lines across the layers trace the positions of one continuous lamination—type three. In type two, however, the laminations are joined at the beginning and end of each turn. The differential equation which applies to the pth layer is:

$$2\,\rho\,\frac{\partial ç}{\partial x} - j\,\frac{4\,\pi\,\omega}{s}\,I_2$$
$$+\,\frac{\partial}{\partial x}\,j\,\frac{4\,\pi\,\omega}{s}\,\{\,(p-1)\,I_1\,(d-x)$$
$$+\,(p-1)\,I_1\,x\,\} - j\,\frac{4\,\pi\,\omega}{s}\left\{\int_0^x w\,ç\,\partial x\right.$$
$$\left.+\int_d^x w\,ç\,\partial x\right\} = 0 \qquad (11)$$

This readily reduces to:

$$\frac{\partial ç}{\partial x} - j\,\frac{4\,\pi\,\omega}{s\,\rho}\left(\frac{I_2}{2} - \frac{I_1}{2}\right)$$
$$-\,j\,\frac{4\,\pi\,\omega}{s\,\rho}\int_0^x w\,ç\,\partial x = 0$$

Notice that the mutual effect of the layers upon each other is eliminated, by twisting the end connection (third term (11)). The resistance ratio is thus the same for each turn. It is independent of the current in the lower coil side, but it does depend upon the number of layers in the coil side.

$$K = M_r + \frac{n^2 - 1}{4}\,N_r$$

9. Type three: End connections twisted on one side only. The differential equation of the form (1) is:

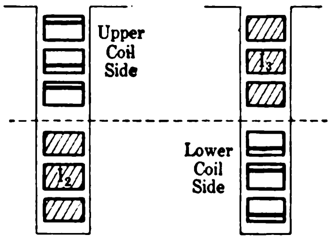

FIG. 6

$$2\,n\,\rho\,\frac{\partial ç}{\partial x}$$
$$+\,\frac{\partial}{\partial x}\,j\,\frac{4\,\pi\,\omega}{s}\,I_2\,\{\,(d-x) + x + (d-x) + \ldots\ldots$$
$$+\,\frac{\partial}{\partial x}\,j\,\frac{4\,\pi\,\omega}{s}\,I_1\left\{\begin{array}{l}(d-x) + 2\,x + 3\,(d-x) + \ldots\ldots \\ +\,x + 2\,(d-x) + 3\,x + \ldots\ldots\end{array}\right\}$$
$$-\,j\,\frac{4\,\pi\,\omega}{s}\,\{\,n\int_0^x w\,ç\,\partial x + n\int_d^x w\,ç\,\partial x\,\}$$

The third term of this equation is always zero, but the second term may or may not be. It is thus apparent that there are two cases to be considered, *viz.*, when the number of layers is even and when it is odd. If n is even the second term is zero and the equation reduces to:

$$\frac{\partial \underset{\cdot}{c}}{\partial x} - j \frac{4 \pi \omega}{s \rho} \left(- \frac{I_1}{2} \right) - j \frac{4 \pi \omega}{s \rho} \int_0^x w \underset{\cdot}{c} \, \partial x = 0$$

Notice that this equation is independent of the number of layers and the current in the lower coil side. This arrangement of an even number of continuously laminated layers whose end turns are twisted on one side only gives the smallest resistance ratio of any of the cases considered.

$$K = M_r - 1/4 \, N_r$$

From the forms of M_r and N_r this is readily shown to be the M_r for a conductor one-half as deep. This same condition of current distribution is obtained by having an even number of laminated conductors side by side in the slots if the end connections are twisted on one side only. The resistance ratio is then independent of the number of layers in the coil. If n is odd, the differential equation reduces to:

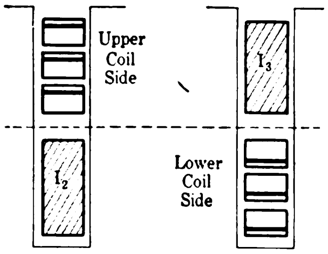

FIG. 7

$$\frac{\partial \underset{\cdot}{c}}{\partial x} - j \frac{4 \pi \omega}{s \rho} \left\{ \frac{I_2}{2 n} - \frac{I_1}{2} \right\} - j \frac{4 \pi \omega}{s \rho} \int_0^x w \underset{\cdot}{c} \, \partial x = 0$$

The resistance ratio is now:

$$K = M_r$$

This ratio is the same as in the case of a *single* solid conductor of the *same* depth, whereas if there are an even number of layers the ratio is the same as for a single solid conductor of one-half the depth of the laminated one.

10. Type three: End connections twisted on both sides (See Fig. 7). The differential equation of the form (1) is:

$$2 n \rho \frac{\partial \underset{\cdot}{c}}{\partial x} + \frac{\partial}{\partial x} j \frac{4 \pi \omega}{s} I_2 (d - x) n + \frac{\partial}{\partial x} j \frac{4 \pi \omega}{s} I_1 \left\{ \begin{array}{l} (d - x) + 2 x + 3 (d - x) \\ \qquad + \ldots\ldots \\ + x + 2 (d - x) + 3 x \\ \qquad + \ldots\ldots \end{array} \right\} - j \frac{4 \pi \omega}{s} \left\{ n \int_0^x w \underset{\cdot}{c} \, \partial x + n \int_d^x w \underset{\cdot}{c} \, \partial x \right\} = 0$$

This reduces to:

$$\frac{\partial \underset{\cdot}{c}}{\partial x} - j \frac{4 \pi \omega}{s \rho} \left(\frac{I_2}{2} - \frac{I_1}{2} \right) - j \frac{4 \pi \omega}{s \rho} \int_0^x w \underset{\cdot}{c} \, \partial x = 0$$

The resistance ratio is:

$$K = M_r + \frac{n^2 - 1}{4} N_r$$

It is independent of the current in the lower coil side. Notice that this is the same ratio as was obtained for case 8.

Enough illustrations of the method and the simplicity of its application have been given. There follows a numerical calculation of the resistance ratios for a given arrangement of conductors of various types. The winding data are: Three-phase with four slots per pole per phase; coil pitch of 10 slots; two turns per coil; conductors 1.5 cm. deep; length of embedded portion and of end turns the same; frequency 60 cycles, the ratio of width of copper to width of slot, 0.6; resistivity, 2100 c. g. s. units.

For solid conductors:

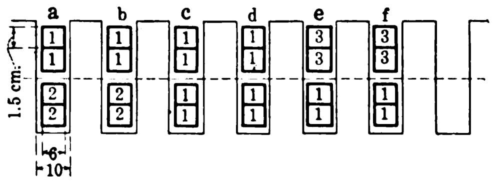

FIG. 8

$$\alpha d_s = 1.5 \sqrt{\frac{8 \pi^2 \times 60 \times 0.6}{2100}} \; \underline{/45^\circ}$$

$$= 1.74 \; \underline{/45^\circ}$$

From curve

$$M_r = 1.20$$
$$N_r = 0.73$$

For laminated conductor:

$$\alpha d = 1.5 \sqrt{\frac{8 \pi^2 \times 60 \times 0.6}{2 \times 2100}} \; \underline{/45^\circ}$$

$$= 1.23 \; \underline{/45^\circ}$$

From curve

$$M_r = 1.05$$
$$N_r = 0.20$$

The arrangement of the conductors of one phase before one pole is shown in Fig. 8. The resistance ratios for phase one are given in the following table for the various cases considered.

TABLE I

SOLID CONDUCTORS	RATIO
Lower coil sides (slots c, d, e & f)	1.93*
Upper " " (" a and b)	6.31*
" " " (" c and d)	7.77*
Entire winding including end turns	2.75†

INFINITELY LAMINATED CONDUCTORS, TYPE 1.

Lower coil sides (slots c, d, e & f)	1.25
Upper " " (" a and b)	2.45
" " " (" c and d)	2.85
Entire winding	1.95

INFINITELY LAMINATED CONDUCTORS, TYPE 2.

Untwisted (slots c and d)	1.85
" (" a, b, e and f)	1.65
" (entire winding)	1.75
Twisted (entire winding)	1.20

INFINITELY LAMINATED CONDUCTORS, TYPE 3.

Untwisted (slots c and d)	1.80
" (" a, b, e and f)	1.60
" (entire winding)	1.70
Twisted in one end connection (entire winding)	1.005
Twisted in both end connections (entire winding)	1.20

*Embedded portion.

†The ratio of the heat developed in the top conductor of slots, b or c to that developed in the bottom conductor is as $\frac{9.96}{1.20}$ or as 8.3 to 1.

This may be a very important consideration, even more than the resistance ratio for the entire winding.

Leakage Reactance Volts. As previously stated, the entire leakage impedance due to resistance and slot leakage flux lying wholly within the conductors themselves may be computed by the proper combination of equations (**7a**) and (**8a**). This method offers little or no advantage when calculating the resistance. It has been shown that in the case of solid bar winding I_0 equals I_b, (equation **8a**). Thus it is probable that the expressions for reactance are similar to those for resistance except that M_x and N_x would replace M_r and N_r. Such proves to be the case. In the case of laminated conductors, however, there is an added term in the expressions for reactance. Consider the general case of a three-phase fractional pitch winding, a typical arrangement of which is shown in Fig. 8. There will usually be slots in which both coil sides are in the same phase. There will also be slots in which the top coil side is in phase one, for example, and the lower coil side in phase two, together with an *equal* number of slots in which the lower coil side is in phase *one* and the upper coil side in phase three. In the general polyphase case of p phases there will be slots occurring in pairs in which the currents differ in phase by plus and minus π/p radians. Let us designate these symmetrical pairs as fractional pitch slots and those in which the upper and lower coil sides are in the same phase as full pitch slots. Accordingly there are two fractional pitch and two full pitch slots per pole per phase in the winding illustrated in Fig. 8. Let n be the number of layers per coil side and R the true resistance of the conductors considered

1. Solid conductors: Full pitch slots. Apply equations (**7a**) and (**8a**), but divide by the phase current, I_1, in order to obtain the impedance directly. With solid conductors the coefficient of $\alpha^2\, d^2$ in equation (**8a**) is zero. Let p be the number of any conductor measured from the bottom of the slot. There are $2\,n$ conductors in both layers in the slot.

The vector expression for the impedance is:

$$Z = \frac{R}{2\,n}\left\{ \sum_{1}^{2n} \left(M + \frac{p-1}{2}\, N \right) + \sum_{1}^{2n} (p-1)\,(1/2 + p - 1)\, N \right\}$$

The first term is the summation of the resistance drops (equation **7a**) divided by the current; the second term is the summation of the reactive drops per ampere produced in each of the $(p-1)$ conductors below the pth conductor (equation **8a**) by the flux within the latter.

This reduces to:

$$Z = R\left\{ M + \frac{4\,n^2 - 1}{3}\, N \right\}$$

The resistance is the real portion of this expression and the reactance the imaginary portion. Thus:

$$r = R\left\{ M_r + \frac{4\,n^2 - 1}{3}\, N_r \right\}$$

$$x = R\left\{ M_x + \frac{4\,n^2 - 1}{3}\, N_x \right\}$$

2. Solid conductors: Fractional pitch slots (taken in pairs as described). The expression for the impedance reduces to

$$\begin{aligned} Z = \frac{R}{2\,n} \Bigg\{ & \sum_{1}^{n} \left[M + \left(\frac{p-1}{2} + n\,\underline{/\theta} \right) N \right] \\ & + \sum_{1}^{n} \left[M + \frac{p-1}{2}\, N \right] \\ & + \sum_{1}^{n} (p-1) \left[\frac{1}{2} + (p-1) + n\,\underline{/\theta} \right] N \\ & + n \sum_{1}^{n} \left[\frac{\underline{/-\theta}}{2} + (p-1)\,\underline{/-\theta} + n \right] N \\ & + \sum_{1}^{n} (p-1) \left[\frac{1}{2} + (p-1) \right] N \Bigg\} \end{aligned}$$

The first two terms are respectively the summations of the resistance drops per ampere (equation **7a**) in the upper and lower coil sides; the third term is the summation of the reactive drops per ampere produced in each of the $(p-1)$ conductors below the pth conductor of the upper coil side (equation **8a**) by the flux within the latter due to its own current and all of that below it in the slot; the fourth term is the reactive drop (equation **8a**) in the lower coil side due to the flux within the coil side above it which carries

a current having a relative phase angle of $\angle{-\theta}$; the last term is the summation of the reactive drops per ampere produced in each of the $(p-1)$ conductors below the pth conductor of the lower coil side (equation **8a**) by the flux within the latter.

This reduces to:

$$Z = R\left\{ M + \left(\frac{5\,n^2-2}{6} + \frac{n^2}{2}\cos\theta \right) N \right\}$$

The resistance is:

$$r = R\left\{ M_r + \left(\frac{5\,n^2-2}{6} + \frac{n^2}{2}\cos\theta \right) N_r \right\}$$

The reactance is:

$$x = R\left\{ M_x + \left(\frac{5\,n^2-2}{6} + \frac{n^2}{2}\cos\theta \right) N_x \right\}$$

This expression is general for both fractional and full pitch slots. For the latter θ equals zero.

3. Finely and continuously laminated conductors (type three) with untwisted end connections. Consider the general case of symmetrical pairs of fractional pitch slots in which the currents in the coil sides lying in the same slot differ in phase by plus and minus θ. R is the true resistance of one coil. In this case

$$I_0 = \frac{n-1}{2} I_1 + \frac{I_2}{2} \ ;$$

where I_2 is the current in the lower coil side.

$$\begin{aligned} Z = \frac{R}{2\,n} & \Bigg\{ 2\sum_1^n \left[M + \left(\frac{n-1}{2\times 2} + \frac{n\angle\theta}{2\times 2} \right) N \right] \\ & + \sum_1^n (p-1) \Bigg[\left(\frac{1}{2} + \frac{n-1}{2} + \frac{n\angle\theta}{2} \right) N \\ & \qquad + \left(p - 1 + n\angle\theta - \frac{n-1}{2} - \frac{n\angle\theta}{2} \right) \alpha^2 d^2 \Bigg] \\ & + n\sum_1^n \Bigg[\left(\frac{\angle{-\theta}}{2} + \frac{n-1}{2}\angle{-\theta} + \frac{n}{2} \right) N \\ & \qquad + \left((p-1)\angle{-\theta} + n - \frac{n-1}{2}\angle{-\theta} - \frac{n}{2} \right) \alpha^2 d^2 \Bigg] \\ & + \sum_1^n (p-1) \Bigg[\left(\frac{1}{2} + \frac{n-1}{2} + \frac{n\angle\theta}{2} \right) N \\ & \qquad + \left(p - 1 - \frac{n-1}{2} - \frac{n\angle\theta}{2} \right) \alpha^2 d^2 \Bigg] \Bigg\} \end{aligned}$$

The first term is the summation of the resistance drops per ampere (equation **7a**) in the upper and lower coil sides. Due to the fact that laminations are continuous the current distribution is the same in each conductor of the coil. Thus the resistance drops are also the same for each conductor. The second, third and fourth terms respectively correspond to the third, fourth and fifth terms in the preceding case.

This reduces to:

$$Z = R\left\{ M + \left(\frac{2\,n^2-1}{4} + \frac{n^2}{2}\cos\theta \right) N + \frac{4\,n^2-1}{12}\,\alpha^2 d^2 \right\}$$

The resistance and reactance are respectively the real and imaginary portions of this expression. Thus:

$$r = R\left\{ M_r + \left(\frac{2\,n^2-1}{4} + \frac{n^2}{2}\cos\theta \right) N_r \right\}$$

$$x = R\left\{ M_x + \left(\frac{2\,n^2-1}{4} + \frac{n^2}{2}\cos\theta \right) N_x + \frac{4\,n^2-1}{12}\,|\alpha|^2 d^2 \right\}$$

$|\alpha|^2$ is the square of the numerical value of α, *viz.*, $\dfrac{8\,\pi^2\,w\,f}{\rho\,s}$.

4. Finely and continuously laminated conductors (type three) with end connections twisted on both sides. Consider the general case of symmetrical pairs of fractional pitch slots in which the currents in the coil sides lying in the same slot differ in phase by θ. Due to the twist in the end connections the current density is the same at points equally distant from the bottom of half of the conductors, and from the top of the other half. The expression for the flux within the conductor has already been given for the first condition. When current density is measured from the top of the conductor, the expression for the flux within it is:

$$\varphi = \frac{4\,\pi}{s} \int_d^0 \partial x \int_d^x w\, c\, \partial x$$

This readily reduces to:

$$\varphi = \frac{1}{j\,\omega}\,\frac{\rho}{w\,d} \left\{ (I_1 + I_0)\,\alpha^2 d^2 - \left(\frac{I_1}{2} + I_0 \right) N \right\}$$

The total flux within the conductor including that produced by the current, I_b, below it is:

$$\varphi_0 = \frac{1}{j\,\omega}\,\frac{\rho}{w\,d} \left\{ (I_1 + I_0 + I_b)\,\alpha^2 d^2 - \left(\frac{I_1}{2} + I_0 \right) N \right\}$$

The voltage produced in every conductor below the one in question by this flux is:

$$E = R\left\{ (I_1 + I_0 + I_b)\,\alpha^2 d^2 - \left(\frac{I_1}{2} + I_0 \right) N \right\}$$

where R is the true resistance of a half turn.

For conductors in which the current density is given for values of x measured from the top, rather than from the bottom, the resistance drop $\rho\, ç$ is that in the bottom element. The flux within this conductor then produces an *additional* voltage in it. In this case

$$I_0 = \frac{I_2}{2} - \frac{I_1}{2}$$

$$Z = \frac{R}{2\,n}$$

$$\Big\{ 2 \sum_1^n \Big[M + \Big(\frac{n \angle\theta}{2 \times 2} - \frac{1}{2 \times 2} \Big) N \Big]$$

$$+ \sum_1^n (p-1) \Big[\Big(\frac{1}{2} + \frac{n \angle\theta}{2} - \frac{1}{2} \Big) N$$

$$+ \Big((p-1) + n \angle\theta - \frac{n}{2} \angle\theta + \frac{1}{2} \Big) \alpha^2 d^2 \Big]$$

$$+ n \sum_1^n \Big[\Big(\frac{\angle -\theta}{2} + \frac{n}{2} - \frac{\angle -\theta}{2} \Big) N$$

$$+ \Big((p-1) \angle -\theta + n - \frac{n}{2} + \frac{\angle -\theta}{2} \Big) \alpha^2 d^2 \Big]$$

$$+ \sum_1^n p \Big[\Big(1 + \frac{n}{2} \angle\theta - \frac{1}{2} + (p-1) \Big) \alpha^2 d^2$$

$$- \Big(\frac{1}{2} + \frac{n}{2} \angle\theta - \frac{1}{2} \Big) N \Big] \Big\}$$

In this expression R is the true resistance of the coil. The terms are written in the same order as in the previous case.

This reduces to:

$$Z = R \; \Big\{ M + \frac{n^2 - 1}{4} \, N + \Big(\frac{7\,n^2 - 1}{12} + \frac{n^2}{2} \cos\theta \Big) \alpha^2 d^2 \Big\}$$

The method of calculating the impedance should now be sufficiently clear. The final equations for the impedance of finely and continuously laminated conductors whose end turns are twisted on one side only are given without showing their detailed construction.

There are two cases to consider,—one with an even number of layers per coil side, and the other with an odd number of layers.

For n, even

$$Z = R \; \Big\{ M - \frac{N}{4} + \Big(\frac{10\,n^2 - 1}{12} + \frac{n^2}{2} \cos\theta \Big) \alpha^2 d^2 \Big\}$$

For n, odd

$$Z = R \; \Big\{ M + \Big(\frac{10\,n^2 - 1}{12} + \frac{n^2}{2} \cos\theta \Big) \alpha^2 d^2 \Big\}$$

The formulas are given in such detail that it must be evident how the effects of unbalanced currents may be calculated. If there are marked harmonics in the currents the heating loss for each harmonic may be calculated as if the others were absent. The resulting loss is the sum of the component losses. The resistance ratios increase with the frequency so that higher harmonics of any considerable magnitude may prove troublesome. For example, if the currents should contain 20 per cent fifth and seventh harmonics, the resistance ratio for the entire winding—solid conductors—would increase from 2.75 as given in Table I to 2.95. This neglects any skin effect in the end turns which would probably be considerable for these harmonics. It also neglects the fact that with higher harmonics there would be a marked magnetic skin effect in the laminations surrounding the conductor which might raise the saturation to such a point that the fundamental assumptions would no longer hold.

The increase in the ratio for the embedded portion only is much more marked. The ratio for the embedded portion of the entire winding as calculated from Table I is

$$\frac{4 \times 1.93 + 2 \times 6.31 + 2 \times 7.77}{8} = 4.49$$

The ratio for the entire embedded portion with harmonics present becomes 6.73. The ratio of the heats developed in top and bottom conductors of slots c or d becomes $\frac{15.8}{1.39}$ or 11.4 when these harmonics are present instead of the value of 8.3 as given in the table.

By making the proper assumptions, this method of analysis allows us to account for the hysteresis and eddy current losses in the armature teeth and core due to the leakage flux, the effect of which we are discussing. Assume that, due to these iron losses, each tube of flux lags behind the net current that is producing it by the same angle, η. If this be the case the reactive drop will lead the resistance drop by $(\pi/2 - \eta)$ radians instead of by $\pi/2$ radians as we have assumed.

Thus $\quad \alpha^2 = \dfrac{8\,\pi^2 f\,w}{\rho\, s} \angle -\dfrac{\pi}{2} - \eta$

and $\quad \alpha = \sqrt{\dfrac{8\,\pi^2 f\,w}{\rho\, s}} \angle \dfrac{\pi}{4} - \dfrac{\eta}{2}$

New values of the complex quantities M and N may be calculated for this value of α and substituted in the expressions for effective resistance and reactance already obtained. Whether or not this method will produce accurate results can only be determined by much experimental research.

SUMMARY OF FORMULAS

SOLID CONDUCTORS

$$\text{Ratio} \quad \frac{\text{Alternating-current resistance}}{\text{Direct-current resistance}}$$

pth conductor from bottom one-coil-side-per-slot bar winding.

$$M_r + p\,(p - 1)\,N_r$$

One-coil-side-per-slot with n layers, or lower coil side with n layers.

$$M_r + \frac{n^2 - 1}{3}\,N_r$$

Upper coil side, n layers, two-coil-side-per slot, fractional pitch.

$$M_r + \left(\frac{4\,n^2 - 1}{3} + n^2 \cos\theta\right) N_r$$

FINELY LAMINATED CONDUCTORS (laminations soldered at beginning and end of each turn) fractional pitch[1]

$$\text{Ratio} \quad \frac{\text{A-C. resistance.}}{\text{D-C. resistance}}$$

End turn untwisted, pth conductor from bottom of upper coil side.

$$M_r + [p^2 - p + n\,(p - 1/2)\cos\theta + n^2/4]\,N_r$$

End turn untwisted, each coil side.

$$M_r + \left(\frac{7\,n^2 - 4}{12} + \frac{n^2}{2}\cos\theta\right) N_r$$

End turn twisted, each coil side.

$$M_r + \frac{n^2 - 1}{4}\,N_r$$

1. Two coil sides per slot, n layers per coil side.

FINELY LAMINATED CONDUCTORS, soldered at the beginning and end of each coil. Ratio of impedance to direct current resistance is given for a pair of coil sides below one of which is current lagging by θ and above the other current leading by θ. n layers per coil side.[2]

End turns untwisted.

$$M + \left(\frac{2\,n^2 - 1}{4} + \frac{n^2}{2}\cos\theta\right) N + \frac{4\,n^2 - 1}{12}\,\alpha^2 d^2$$

End turns twisted both sides.

$$M + \frac{n^2 - 1}{4}\,N + \left(\frac{7\,n^2 - 1}{12} + \frac{n^2}{2}\cos\theta\right)\alpha^2 d^2$$

End turns twisted one side, n even.

$$M - \frac{N}{4} + \left(\frac{10\,n^2 - 1}{12} + \frac{n^2}{2}\cos\theta\right)\alpha^2 d^2$$

End turns twisted one side, n odd.

$$M + \left(\frac{10\,n^2 - 1}{12} + \frac{n^2}{2}\cos\theta\right)\alpha^2 d^2$$

2. In calculating the impedance only leakage flux that lies within the conductors is considered. There are well known methods for calculating the reactance due to other leakage flux.

Carrier Current Telephony and Telegraphy

E. H. COLPITTS and O. B. BLACKWELL
Western Electric Co. American Telephone & Telegraph Co.

(*Continued from page 315 of JOURNAL for April, 1921.*)

Repeaters. From the discussion of the transmission characteristics of lines which will be given later in the paper, the very great practical importance of amplifying apparatus at intermediate points on a line employing carrier frequencies will be evident. For this purpose fortunately we have available, first, the vacuum tube, and, second, a large variety of methods of applying this tube which have been developed to a high state of efficiency in connection with the voice frequency telephone repeater. While, as just indicated, the same general considerations apply to repeaters for carrier current circuits as to repeaters on circuits operated at voice frequencies, the conditions peculiar to carrier current operation require that the repeaters for this service differ quite considerably from standard voice frequency repeaters.

In the first place, on a multiplex carrier current circuit a single repeater installation must handle the energy associated with a number of independent conversations. This could be accomplished by making the installation include a number of repeaters in parallel with suitably associated filter combinations, but it is at once obvious that it is much preferable to install but one repeater channel capable of amplifying all the carrier transmission. The requirements for the repeater set are made still more severe by the fact that modulation in the repeater tubes, which tends to increase with the load, introduces disturbing factors in carrier operation which are not serious in ordinary repeater operation. The reason for this is that the combination frequencies resulting from the interaction of the currents in two channels may lie in the frequency

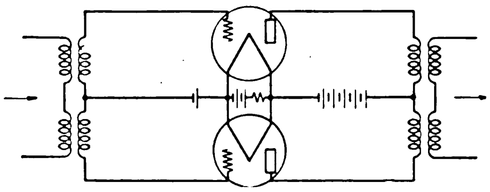

FIG. 21

range of a third, in which case they are transmitted through the selective circuits of that channel and appear as an interfering noise or tone at the subscriber's station. To obtain sufficient energy carrying capacity, and to overcome to some degree this difficulty of intermodulation, we use a number of tubes in parallel in the so-called "push-pull" arrangement. The principle of the push-pull amplifier is shown in Fig. 21.

In this arrangement the input voltage is applied in such a way as to increase the grid voltage of one tube

with respect to its filament at the same time that the grid voltage of the other is diminished. The plates are connected with the output circuit by a differential transformer, so that the useful amplified currents from the two tubes are added, while the more troublesome of the interfering components due to modulation are equal in amplitude and opposite in phase, and are balanced out. Instead of employing tubes in parallel to increase the energy capacity of the set, it would have been possible to have used a single tube of larger energy capacity. The scheme of using a number of tubes operating in parallel was adopted in order to avoid increasing the number of types of tubes in the plant.

In repeater operation at voice frequencies, the amount of amplification which can be secured on a given line and with given types of repeater apparatus is limited by the tendency to "sing." The same is true for repeater operation at carrier frequencies. To reduce the tendency of the repeater to sing, the same methods may be adopted as are employed at the terminals; that is to say, if the same frequencies are used for the transmission in both directions, the lines on either side of the repeater must be balanced and the same general type of repeater circuit used as for voice frequency telephone repeaters (see Fig. 22). If, however, different frequencies are employed for transmission in the two directions, filters may be used to prevent the currents sent out in one direction from passing into the input circuit of the repeater set which receives energy from that direction.

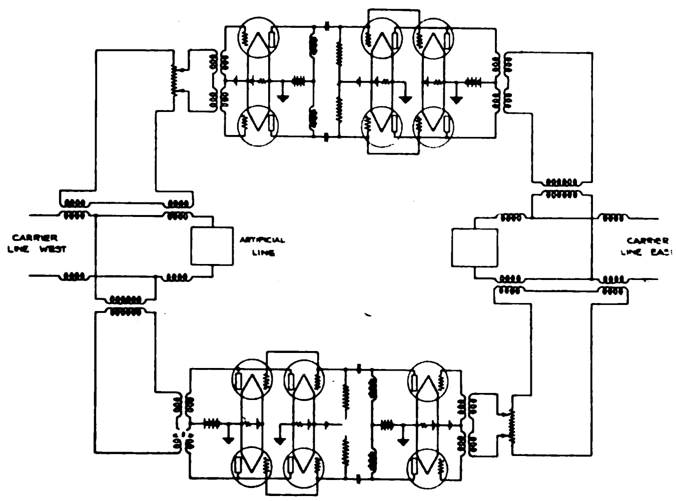

FIG. 22

While the telephone currents at voice frequencies may be amplified in the same repeater along with the carrier currents, it has been found convenient for reasons of plant flexibility to separate voice frequencies from carrier frequencies by line filters similar to those used at the terminals. Due to the fact that the attenuation of voice frequencies is much lower than that of carrier frequencies, it is frequently not necessary to install a voice frequency repeater at all of the points where carrier frequency repeaters are installed. A number of arrangements are illustrated in the sections dealing with commercial systems.

Signaling over Carrier Telephone Circuits. For a carrier telephone channel to form an integral part of an ordinary telephone connection, it is in general desirable to be able to operate the normal signaling mechanism over the channel without the intervention of an operator at the terminals of the carrier section. This is accomplished by two distinct methods in the two types of system employed. In the type where carrier current is transmitted over the line, an auxiliary rectifier tube is associated with the demodulator in such a manner that the incoming carrier current produces in the output circuit of this rectifier a direct current sufficient to maintain a relay in its operated position. When the operator signals, the ordinary 16-cycle ringing current is received at the carrier terminal. This is made to operate a relay, which disconnects the source of carrier current from the modulator, thereby stopping its transmission over the line. As a result, at the distant terminal the relay controlled by the rectified current falls back, causing an ordinary 16-cycle ringing current to be sent out over the connecting line associated with that particular channel.

In the system where the carrier current is suppressed, the 16-cycle ringing current from the low-frequency line operates a relay which applies to the modulator, through the speech circuit, a current of 133 cycles from a vacuum-tube oscillator or other source. This current interacts with the carrier current in the modulator to produce a side band current, differing from the carrier by 133 cycles, which is transmitted to the distant terminal. Here it is demodulated and appears in the voice frequency circuit as a current of 133-cycle frequency. This current operates a relay tuned to this frequency, which in turn serves to send out 16-cycle ringing current over the low-frequency line.

Actual circuit arrangements showing these two methods of signaling are shown in the sections of this paper describing commercial systems.

Telegraph. Carrier current telegraphy is based on the same fundamental principles as carrier current telephony, but in actual operation it employs somewhat different physical arrangements, owing to the differences in the nature of the signals to be transmitted and to the differences between the operating conditions met in the two cases.

In ordinary telegraphy the signaling current consists of a succession of so-called "marking pulses" separated by intervals of zero or oppositely directed current representing spaces. In transmitting telegraph signals over a line by the carrier method, the signaling current, as received from the local telegraph trunk or from a connecting long-distance telegraph line, operates a relay which controls the application of carrier current to the high-frequency line. The usual arrangement is such that high-frequency current of uniform amplitude is sent out during the marking

intervals only. At the receiving terminal this high-frequency current is rectified, generally after amplification, by a vacuum tube. The resulting rectified current operates a relay, which in turn sends signals over the connecting telegraph circuit or loop. Fig. 23 shows a simple, one-way carrier telegraph circuit with one-way direct-current telegraph loops at either end.

It has sometimes been assumed that the only frequency transmitted under these conditions is that of the carrier, and that therefore the only limitation on the frequency intervals between the carriers of adjacent channels is that imposed by the degree of selectivity possible of attainment with actual physical apparatus. That this is not the case is easily seen from a consideration of the building up and decay of current in a sharply resonant circuit. If the time required for the current to build up in such a circuit is comparable with the lengths of the marking and spacing intervals, the high-frequency current will not accurately reproduce the telegraph signals. This causes a rounding off of the signal, or, if it is sufficiently extreme, the signals disappear altogether.

To determine quantitatively the relation between the constants of the selective circuits and the speed and quality of the signals, it is most convenient to regard the problem as a case of modulation. As in telephony it was shown to be necessary to transmit a band of frequencies equal in width to the voice frequency range, similarly in carrier telegraphy it is necessary to transmit a band of high frequencies corresponding to the important frequencies present in the direct-current telegraph signals. An analysis of the ideal current wave representing a succession of telegraph signals reveals the presence of an infinite series of components whose frequencies extend to infinity and whose amplitudes decrease with increasing frequency. Ordinary telegraph circuits transmit only components of comparatively low frequency, with the result that the signals are rounded off. Reasonably good signals are secured, however, if those components are preserved whose frequencies are a few times the fundamental interruption frequency. The upper limit of this essential frequency band varies with different types of apparatus and with different grades of service required, but it is for any one set of conditions roughly proportional to the speed of signaling. For the cases so far met with in practise, it is of the order of 100 or 200 cycles. It follows, therefore, that while a modulated wave, whose envelope approximates ideal telegraph signals, would require the transmission over the line of a very wide band of frequencies, satisfactory operation requires the transmission of a band of frequencies equal only in width to the essential frequency range of ordinary telegraphy. In case of multiplex carrier telegraph operation, the non-essential frequency components are accordingly suppressed by the selective sending circuits, so as to prevent them from interfering with other channels.

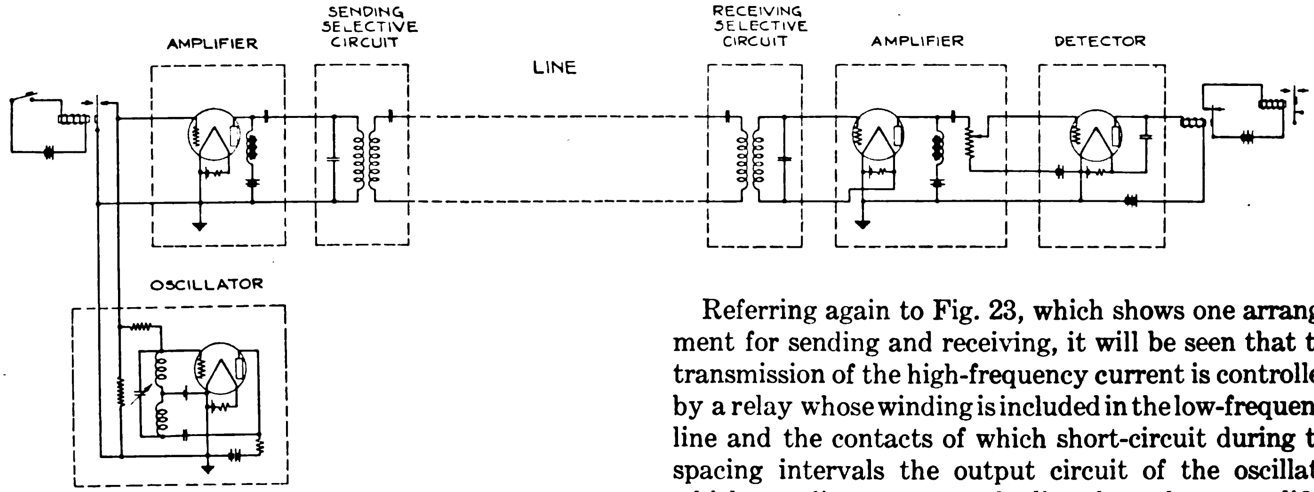

Fig. 23

Referring again to Fig. 23, which shows one arrangement for sending and receiving, it will be seen that the transmission of the high-frequency current is controlled, by a relay whose winding is included in the low-frequency line and the contacts of which short-circuit during the spacing intervals the output circuit of the oscillator which supplies energy to the line through an amplifier. At the receiving terminal the arrangement for demodulation or detection requires some further explanation. The carrier current, after suitable amplification, is applied to the input circuit of a vacuum-tube detector. The grid of this tube is made just sufficiently negative to prevent the flow of current in the plate circuit, which includes the winding of a relay, when no high-frequency current is being received from the line through the amplifier. During the marking intervals a high-frequency alternating potential is applied to the grid, causing a high-frequency pulsating current to flow in the plate circuit and operate the relay which is adjusted so as to be held in the operated position for the duration of the signal. The contacts of this relay control the sending of signals over the connecting telegraph circuit.

Referring to the question of multiplex operation, it may be mentioned that where the carrier frequency is of the order of several thousand cycles, the percentage difference in frequency between the extreme edges of the side band is so small, that it is not so readily possible to design circuits to suppress one of the side bands,

as can be done in the case of telephony. For this reason, the frequency range assigned to a carrier telegraph channel has been twice that of the essential frequency range of the direct-current telegraph channel. As is obvious from previous consideration, the advantages of band filters largely disappear for narrow transmission bands at high frequencies, and in telegraphy it has been found more convenient, for the signaling speed so far met with, to use loosely coupled resonant circuits, such as are shown in Fig. 23.

A frequent condition of two-way operation involves what in ordinary telegraph working is termed "full-

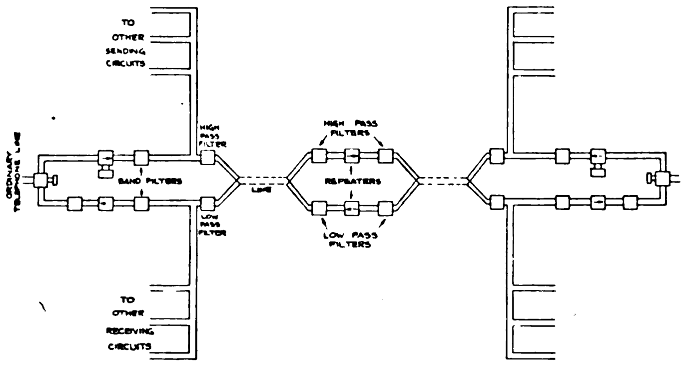

FIG. 24

duplex operation," where the oppositely directed channels are used simultaneously for independent messages. In ordinary telegraphy this full-duplex operation is secured by balanced bridge arrangements which involve at each terminal a close balancing of the actual line by an artificial line. This close balancing at low frequencies is secured by rather close attention of a repeater operator and rather frequent readjustments of the artificial line constants. While it is possible to adapt such an arrangement to the carrier telegraph line, it has not been found economical to do so because of the ease of securing full-duplex operation by the use of different carrier frequencies for the two directions. The extension of this method to multiplex operation is obvious. A very convenient frequency arrangement for carrier telegraphy has been found to be that in which transmissions in one direction occupy a range of frequency from 3300 to 6000 cycles, and those in the other direction from very slightly above 6000 to 10,000 cycles. By proper terminal arrangements this will provide on a single pair of wires the equivalent of ten full-duplex telegraph channels. From what has been said, it will appear that there is left still available a substantial frequency range which may, if desired, be used to provide either other telegraph channels, or, if the needs of the service require them, additional telephone channels.

Frequency Assignments. From the statements regarding filters and the methods of obtaining two-way operation, it will be evident that it is possible to select the frequencies for the various telephone and telegraph channels in a variety of ways. What assignment of frequencies to the various channels is best suited to a particular installation depends upon the engineering and economic considerations involved. For example, where there is only a single pair of wires available and it is desired to secure over this pair as many carrier telephone channels as possible, it may be economical to go to considerable expense in securing sufficient uniformity in the line so that its impedance can be readily balanced by the artificial line networks, thereby making it possible to use the same range of frequency for securing a two-way telephone channel. The harmonic frequency arrangement already described is particularly useful in such a case.

If, however, it is desired to operate carrier systems over a number of pairs of wires on the same lead, considerations of cross-talk, which will be explained more fully later in a section dealing with lines, make it highly desirable that different frequencies be used for operation in the two directions. Under this condition it is not necessary to secure the uniformity of line impedance which is required when the same frequency is employed in both directions. Of the possible frequency assignments for the oppositely directed channels, one which has proved very convenient is that in which all of the channels in one direction employ carrier frequencies below a certain value, and all the channels in the opposite direction carrier frequencies above this value. This grouped arrangement simplifies the selective circuits both at the repeater points and at the terminals; for the separation between oppositely directed currents which is accomplished by the balancing of the high-frequency line when the

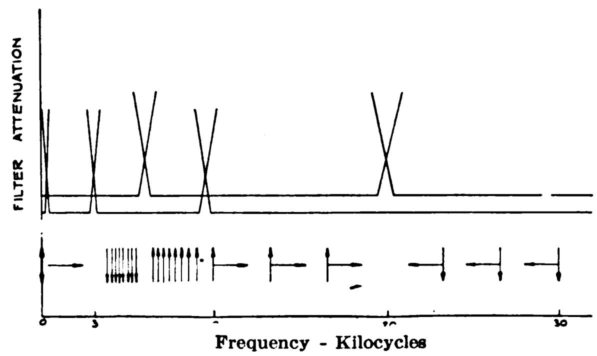

FIG. 25

same frequencies are used in both directions can, with this grouped arrangement, be accomplished by a combination of high- and low-pass filters of the type shown in Fig. 15. Fig. 24 shows schematically a carrier telephone system employing filters of this sort both at the terminals and at an intermediate repeater station.

A very workable assignment of frequencies to telephone and telegraph on the same pair is shown in Fig. 25. The arrows at the lower part of the figure indicate the positions assigned in the frequency scale to the different types of transmission. Beginning at zero frequency there is assigned to the direct-

current telegraph a narrow band. The range extending from 200 to 2000 cycles and represented by the horizontal arrow is the frequency band of ordinary telephony. In the interval between 3333 and 6000 cycles is a group of eight one-way carrier telegraph channels indicated by vertical arrows. In the interval between 6000 and 10,000 are the eight oppositely directed channels, which with those of lower frequency may

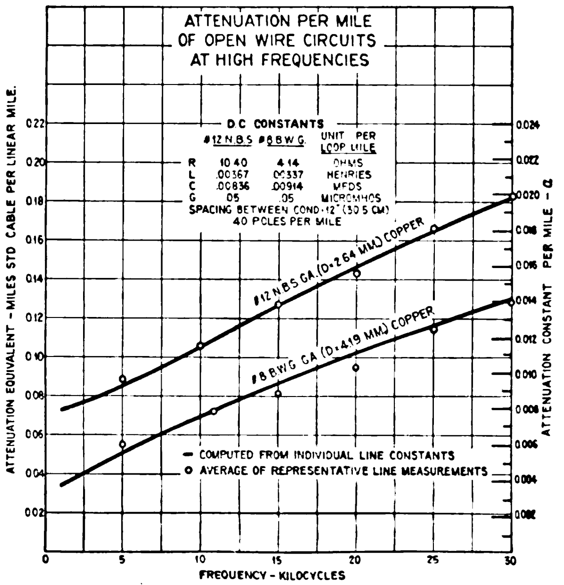

Fig. 26

constitute eight full duplex telegraph circuits. The frequency range above 10,000 is assigned to three two-way carrier telephone channels. These are each designated by a vertical arrow indicating the position of the carrier frequency and the direction of transmission, and a horizontal arrow indicating the position of the side band with respect to the carrier frequency.

Above there are given, one above the other, the idealized attenuation characteristics of a pair of separating filters for use with this assignment of frequencies. The lower of the two is so designed that each filter transmits only those frequencies which are assigned to one particular purpose. Such filters would be used for separating into individual circuits the currents used for carrier telephony, carrier telegraphy, ordinary telephony and ordinary telegraphy and thus facilitating their distribution in the central offices. The filters shown above are used, as is illustrated in Fig. 23, for separating in the carrier current circuits the currents transmitted in opposite directions.

Lines

General. The electrical design of carrier systems is determined in large part by the problems which arise in the transmission of the carrier currents over the line wires. The comparatively high frequencies used in carrier transmission attenuate much more rapidly in passing along the lines, and have a much greater tendency to cause interference in adjacent circuits than do the ordinary telephone frequencies. Both attenuation and interference increase rapidly with increase in frequency. Because of this it has been found most economical to make use of the frequency range commencing immediately above the voice range. The systems which have so far been put into commercial use employ frequencies up to about 30,000 cycles.

Because of the high attenuation and interference, carrier transmission is particularly dependent on the use in the circuit of repeaters placed at comparatively frequent intervals. To indicate the importance of repeaters, it is interesting to note that if the Harrisburg-Chicago carrier telephone system, which spans about 750 miles, as described below, were operated without repeaters, it would be necessary under the most favorable line conditions to apply at the sending end of the highest-frequency channel a power of 60 kilowatts. By the use of intermediate repeaters the high-frequency power at no point exceeds 0.1 watt.

Some of the experimenters in this art have had the misconception that the mode of transmission of the high frequencies employed in carrier operation was different from that of the ordinary telephone frequencies, and that the carrier frequencies had some unexplained property whereby, although guided by the line wires, large energy losses in the line wires were avoided. There is, however, no theoretical or experimental basis for this idea. As a matter of fact, the line attenuation of carrier currents is considerably

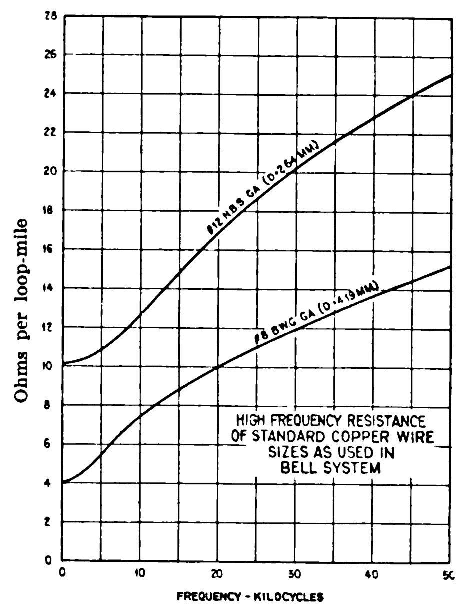

Fig. 27

greater than for telephone frequencies and increases rapidly with frequency, due to the increased resistance of the line wires, and increased effective leakage between the line wires at the carrier frequencies. While it is, of course, proper to picture the mechanism of carrier transmission as one in which the energy is contained in the electromagnetic waves, which are guided by the line wires, this is no less true for the transmission of low frequencies. The difference between

radio and wire transmission, whether of high or low frequency, is the difference between unguided and guided waves.

Open Wire Characteristics at Carrier Frequencies. The two sizes of wire in most common use for open-wire telephone lines in this country are No. 12 N. B. S. gage (0.104 in. diameter) and No. 8 B. W. G. (0.165 in. diameter). These wires are strung on pole lines with a normal separation of twelve inches between their centers.

The curves of Fig. 26 give the values of the attenuation constant[22] at different frequencies for circuits of these sizes of wire. The attenuation follows the usual line formulas. That is, the ratio of the currents

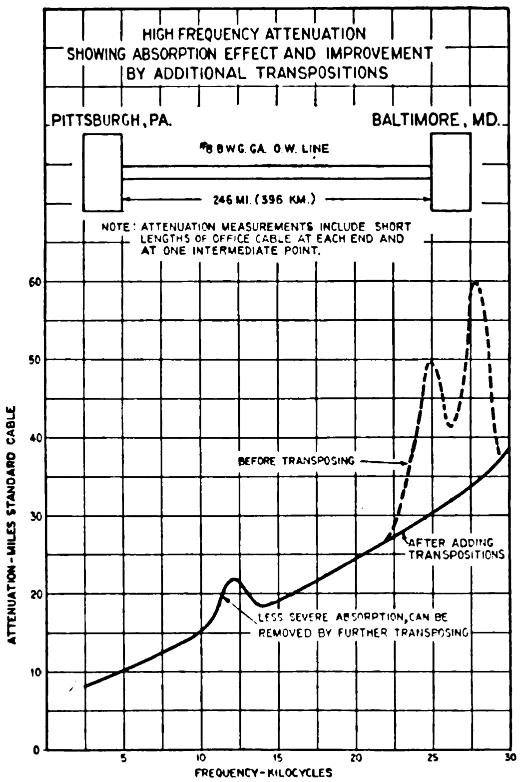

FIG. 28

i_1 and i_2 at two points on a transmission line separated by a distance l, assuming the line so terminated as to make reflection effects negligible, is

$$\frac{i_2}{i_1} = e^{-l\alpha}$$

in which α is the real part of the expression

$$\sqrt{(R + j\,p\,L)\,(G + j\,p\,C)}$$

In this expression R and L are the effective loop series resistance and inductance per unit length and G and C are the effective conductance and capacitance between the wires, per unit length.

22. NOTE: A convenient practical unit of attenuation which has gained large use in telephone engineering is that of the "mile of standard cable," in which α at 800 cycles equals 0.109. The attenuation at carrier frequencies is expressed in terms of the miles of standard cable which at 800 cycles has the same attenuation.

The formulas covering the action of transmission lines to alternating currents are so well understood[23] that the discussion here will be limited to certain

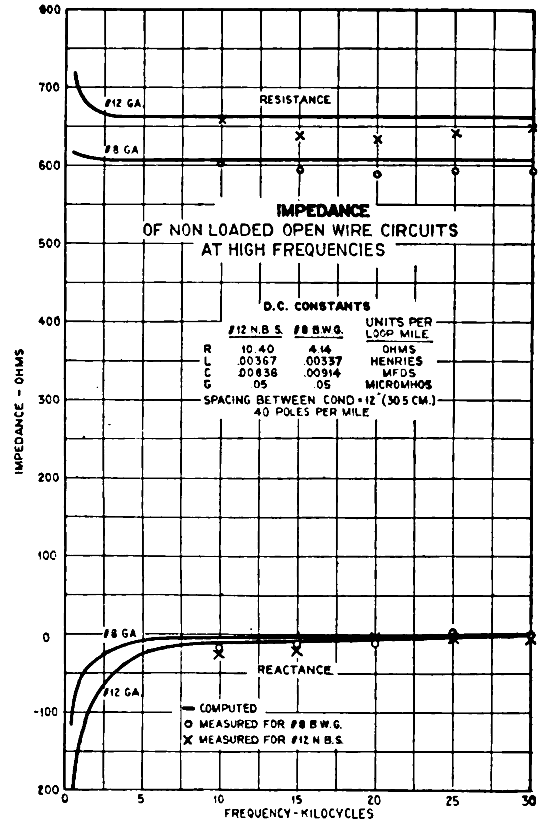

FIG. 29

features of particular interest in connection with carrier systems.

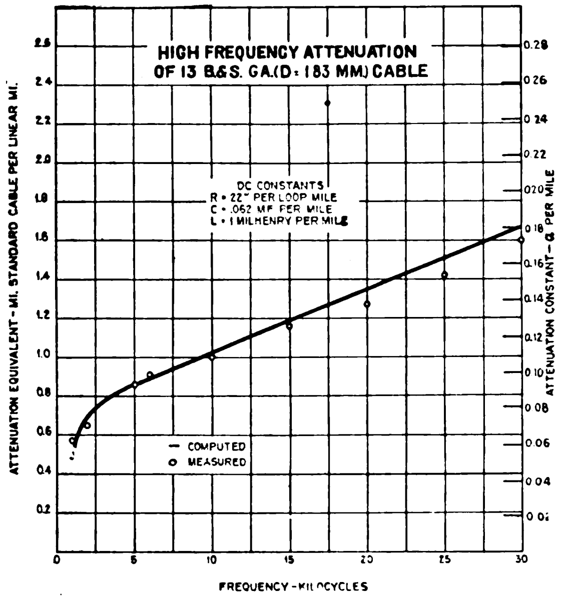

FIG. 30

23. J. A. Fleming: "The Propagation of Electric Currents in Telephone and Telegraph Conductors."

A. E. Kennelly: "The Application of Hyperbolic Functions to Electrical Engineering Problems."

John Mills: "Radio Communication, Theory and Methods, with an Appendix on Transmission over Wires."

It is found that the constants L and C are practically the same at high as at low frequencies. R may be computed by the usual "skin effect" formulas. Its rapid increase in value with increase in frequency is shown in Fig. 27.

The determination of G represents a more difficult task since no theoretical relation has been established

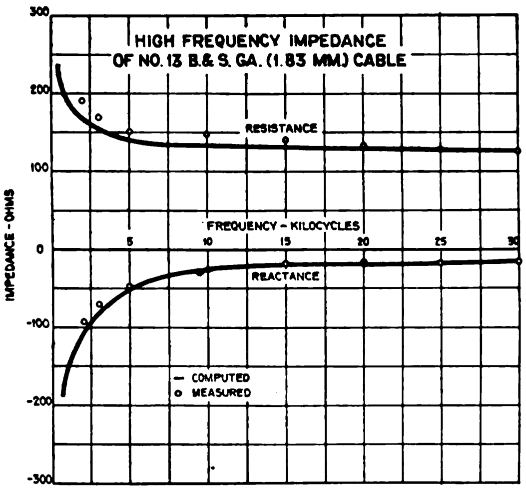

Fig. 31

between the effective conductance between the wires and frequency. In computing the curve shown, the value of G was taken from measurements of the effective insulation of a group of glass line insulators exposed to ordinary weather conditions, and assumes therefore that the effective leakage occurs only at the insulators. The conductance, for example, at 25 kilocyles, under

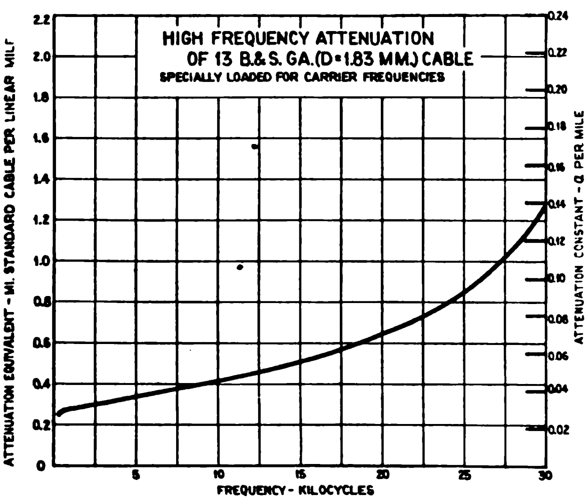

Fig. 32

normal dry weather conditions, is found to be roughly 200 times that measured with direct current. It will be noted that the curves computed with the values of the constants so obtained are checked very closely by the actual field measurements which are indicated on the curves by small circles. Since the leakage plays a large part in determining the attenuation, substantial changes in attenuation occur for varying weather conditions. Under wet weather conditions the attenuation will rise materially higher than that shown in the above curve.

The apparent attenuation of a circuit may be largely increased by the setting up of induced currents in adjacent wires carried on the same pole line. This is illustrated in the curve of Fig. 28, which is for one of the circuits employed in the operation of the first commercial carrier telephone system between Baltimore and Pittsburgh. The dotted curve represents excess attenuation originally found in the circuit due to such absorption. After additional transpositions had been cut into the circuit it finally gave the attenuation shown

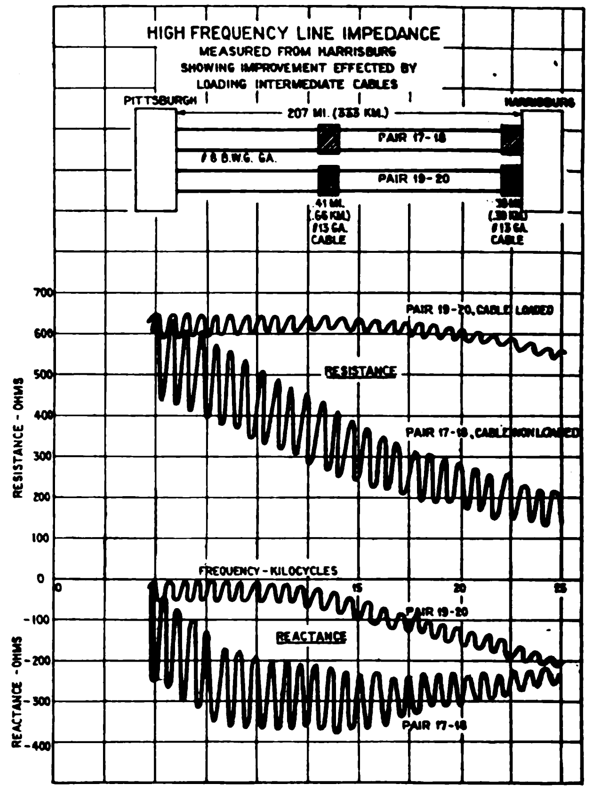

Fig. 33

in the full line curve. The smaller attenuation hump shown in the curve at about 12,000 cycles was not eliminated, as its effect was not considered sufficiently serious to justify the expense of further transpositions.

The impedance of a circuit as viewed at terminal and intermediate repeater points is important in determining the proportioning of the connecting apparatus and in determining the amount of amplification which can be given, in systems depending on balance. Fig. 29 shows the impedance characteristic of a long No. 8 B. W. G. circuit. The curves follow the usual line formulas for characteristic impedance. It will be noted that the impedance is practically a pure resistance with a value of approximately 600 ohms. The fact that the reactance component is negligible makes it possible to design the selecting circuits regardless of the particular line over which a system is to operate.

The effect on repeater amplification of irregularities in impedance is covered in the section under "Line Balancing" below.

Cable. Transmission over cables will be discussed here in connection with the unavoidable use of short lengths of cable in open wire lines, for toll entrance in bringing the circuits into the central offices, at river crossings, in passing through cities, etc. Such lengths of cable have two effects:

a. They introduce a considerable transmission loss due to the inefficiency of cable circuits at these higher frequencies, and

b. They introduce a large irregularity in impedance characteristics which, in systems depending on balance for duplex operation, affects radically the amount of amplification which may be obtained at repeater points.

Fig. 30 shows the attenuation, and Fig. 31 shows the

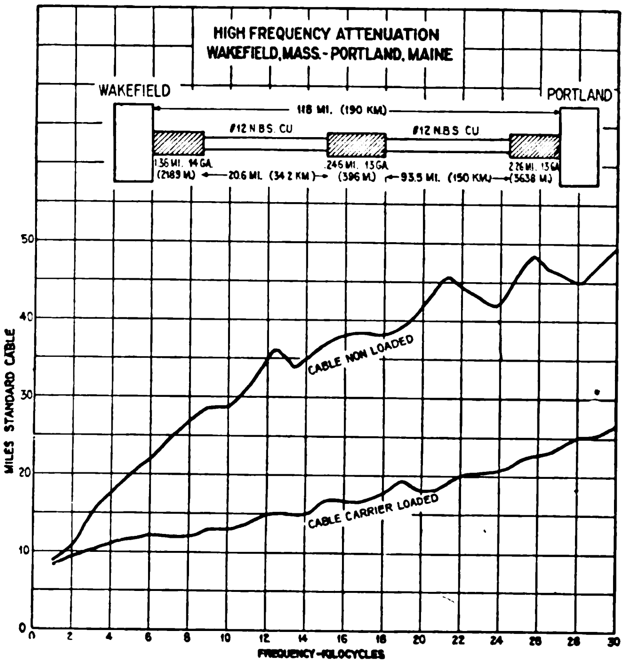

Fig. 34

impedance of a No. 13 B. & S. gage paper-insulated cable circuit of the ordinary telephone type.

To reduce both the attenuation of the circuits at these frequencies and the impedance irregularity which short lengths of cable introduce, there has been developed a system of coil inductance loading.

Loading for Carrier Frequencies. The loading systems which have been developed for cable are adapted to transmit frequencies up to about 30,000 cycles. The coils are spaced about 1000 feet apart, and the amount of inductance is chosen so as to give the cable circuits the same characteristic impedance as the lines to which they are connected. Fig. 32 shows the attenuation of a No. 13 gage cable so loaded.

Fig. 33 shows the impedance of a section of line between Harrisburg and Pittsburg as measured at Harrisburg, including two lengths of cable as indicated in the figure. It will be noted that the impedance when the cables are non-loaded is very irregular. The rapid variations in impedance are caused by reflections from the intermediate length of cable at Altoona, whereas the general drop of the complete impedance curve is due to the terminal cable at Harrisburg. It will be noted in this case that due to the terminal cable the reactance of the circuit as measured from the terminal is not negligible. The decrease in irregularity in impedance as the frequency increases is due to the fact that the attenuation increases with frequency, so that the cable at Altoona is electrically farther away at the higher frequencies. Since, however, the large attenuation has to be made up by larger repeater gains, the smaller apparent irregularity at the higher frequencies is of equal or greater practical importance than that at low frequencies. It will be noted furthermore that the loading largely overcomes the effect of the two lengths of cable. The slight remaining reactance component, which occurs at the higher frequencies, is largely due to the office wiring at the end where the measurements were made; and the slight remaining irregularity is due to some office wiring at Altoona.

Fig. 34 illustrates the effect on attenuation of the loading of intermediate lengths of cable. It shows the improvement introduced in the attenuation of a circuit between Wakefield, Mass., and Portland, Me., due to the loading of three lengths of intermediate cable. This section is a part of the circuit of a carrier telephone installation between Boston, Mass., and Bangor, Me. The importance of loading will be appreciated in this case by noting that at 25 kilocycles the received energy is increased about two hundred times by the loading of the cables.

Under some conditions it has been found convenient to leave lengths of cable in carrier systems unloaded, and to install auto-transformers between the cable and the open-wire circuits to reduce the reflection losses introduced by the cables.

Line Balancing for Two-Way Operation. As already pointed out, two-way operation may be carried out either by the use of different frequencies in the two directions, or by using the same frequency for the two directions but using duplex balancing arrangements at the terminals. When different frequencies are used in the two directions it is sometimes convenient to employ line balance to supplement the selective circuits.

The general problem of line balancing was discussed in some detail in the paper on telephone repeaters already referred to.[24] It will be noted by referring again to the impedance characteristic of a long uniform length of open wire circuit (Fig. 29) that a balance can be obtained by employing an artificial line consisting simply of a non-inductive resistance of about 600 ohms. Moreover, this resistance gives a good balance for all of the channels employed in a carrier system.

24. Gherardi-Jewett, loc. cit.

For systems requiring it, balance must be obtained not only at intermediate repeater points but also at each terminal, since the terminal set is itself inherently a repeater. Fig. 35 shows diagrammatically a typical balancing arrangement in which the open-wire and connected apparatus on one side of the hybrid coil is balanced by a resistance and connected apparatus on the opposite side. The office wiring is balanced by a condenser and the high-pass and low-pass filters in the line are balanced by similar arrangements in the balancing line.

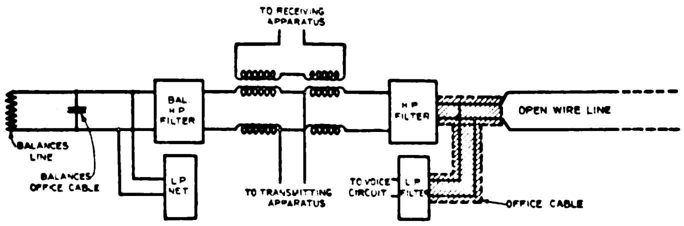

FIG. 35

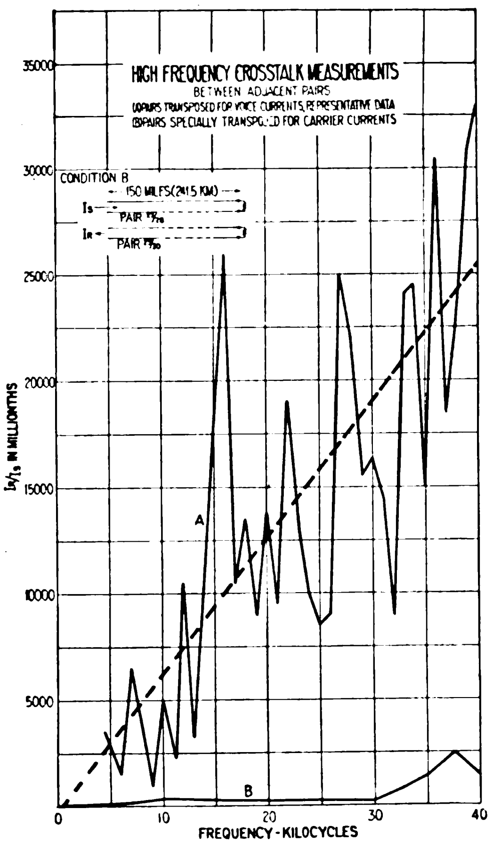

FIG. 36

There has already been pointed out in the section above the manner in which irregularities due to intermediate lengths of cable are cared for by loading. It is important that lines used for carrier operation shall be kept as free as possible from intermediate lengths of cable, lengths of twisted pair, etc. It will be noted that the irregularities in impedance so introduced are similar to those which occur at ordinary telephone frequencies, and were discussed in some detail in the paper on telephone repeaters.

Interference between Circuits—Transpositions. Any general use of carrier systems in the telephone plant requires that it be possible to operate a number of similar systems over the same pole line without mutual interference, that is, to transmit the same range of carrier frequencies over a number of circuits running closely together on the same line, with only negligible interference between channels of different carrier systems.

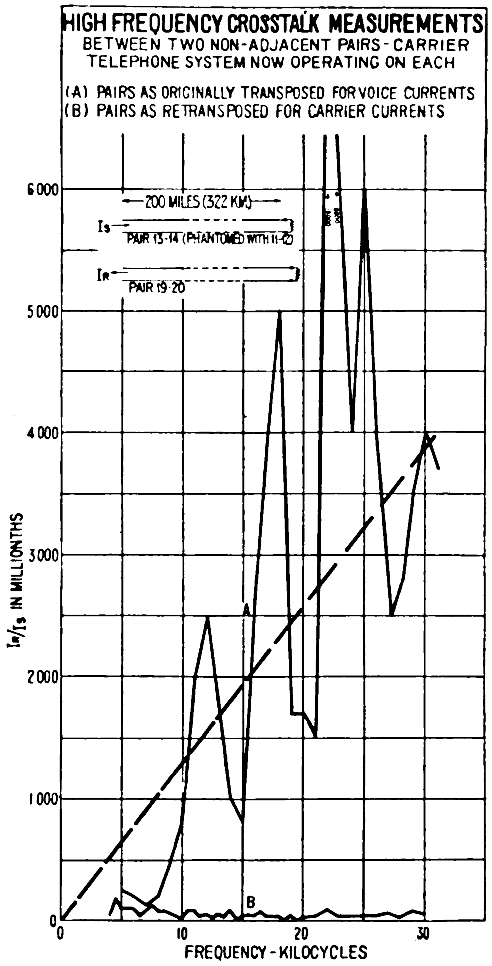

FIG. 37

Inasmuch as the only means available for preventing interference between circuits where the same carrier frequency is employed in both directions is that of balance between circuits, effected by transpositions, it is obvious that where a number of carrier systems are to be operated on the same pole line, the circuits must be operated on the metallic and not on the ground return basis. Metallic circuits are also desirable for reducing foreign high-frequency interference, such as "static" and that from high-power radio stations employing frequencies in the carrier range.

The transpositions existing in open-wire telephone circuits are generally inadequate to balance the cir-

cuits sufficiently accurately for the higher frequencies of carrier transmission.

Fig. 36 shows the values of interference at different frequencies between two pairs of wires which are adjacent on the crossarm. Curve *A* shows typical values for circuits as measured with the ordinary telephone transpositions in them. Curve *B* indicates the great reduction made in the cross-talk by inserting transpositions in both of two circuits extending between Toledo, Ohio and South Bend, Indiana, making the average number per circuit about six per mile. Inasmuch as these circuits are adjacent pairs on the line, the exposure between them is the maximum possible.

In Fig. 37, Curves *A* and *B* show, in the same manner, the cross-talk between two circuits with the ordinary transpositions and after special transpositions had been cut into them. Here the circuits are not immediately adjacent but are separated on the crossarm by two other pairs of wires. The two pairs covered by this figure extend between Harrisburg and Pittsburgh, and are in commercial use for carrier systems.

As a result of a considerable amount of line measurements of the above types with different transposition systems, and from theoretical investigation of cross-talk at these frequencies, it has been determined that the interference limitations are roughly as follows:

Where carrier systems employ the same frequencies for transmission in the two directions, it would not be practicable to operate systems on all the pairs of a line, since the number of transpositions required would be prohibitively large. In fact, in a lead carrying a considerable number of circuits, the transpositions would have to be more closely spaced than are the poles under present standard construction. It is possible, however, to reduce greatly the effect of interference between circuits, by employing systems using different frequencies in the two directions, and arranging so that all of the systems employ the same range of frequencies in each direction. This reduces, of course, the number of two-way channels which may be obtained per pair. It is not certain, however, that even with this arrangement of carrier systems it would be economical to apply carrier to all pairs of a pole line.

Much has already been accomplished, however, in transposing a limited number of pairs on a pole line for carrier operation, and this constitutes the practical problem in most of the present cases; for example, two carrier telephone systems and one carrier telegraph system are operating over the same pole line in the section of the New York-Chicago line between Harrisburg and Pittsburgh, a distance of about 200 miles. While the circuits involved in this case are not adjacent on the crossarm, the systems employ the same frequencies for transmission in opposite directions and therefore represent a severe condition as regards interference.

Noise Interference. As the frequencies used in carrier systems are considerably higher than the harmonics which are generally present in power systems, these circuits are less subject to noise from power interference than are the ordinary telephone

Fig. 38

circuits. They are not free from such interference, however, since high frequencies may be set up in power systems by the charging of lightning protectors, switching, etc. Since the circuits cannot in general be as well balanced to ground at carrier frequencies as at ordinary telephone frequencies, the carrier channels have shown a certain amount of interference from atmospheric electrical effects—that is, so-called

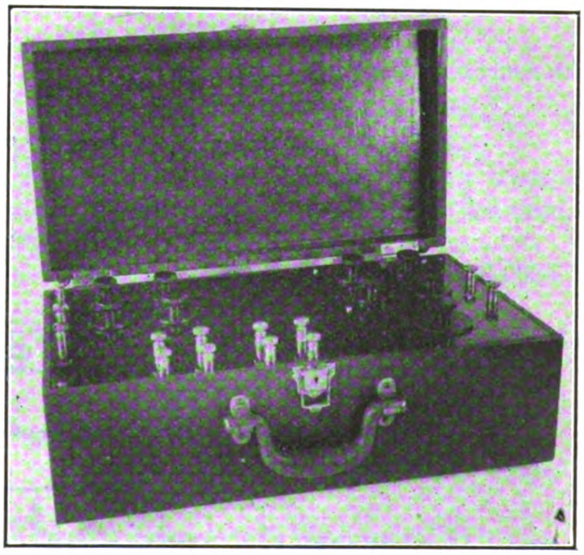

Fig. 39

static. Some interference has also been experienced from high-power long-distance radio systems which are now employing frequencies within the same range.

Line-Measuring Apparatus. To put the lines in proper shape for carrier operation and to maintain

them properly has necessitated the development of a suitable measuring technique and of portable measuring units, including a high-frequency oscillator, high-frequency impedance bridge, detector circuits, thermocouples, etc.

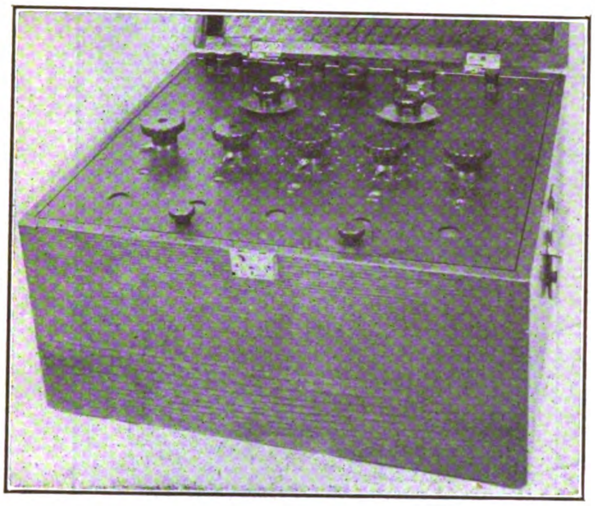

Fig. 40

A photograph of a portable high-frequency oscillator designed for testing work is shown in Fig. 38. This involves the use of four vacuum tubes and affords stable outputs as high as 50 milliamperes into an average line impedance. Its frequency range extends from 100 cycles to 50 kilocycles, and it is designed to operate on telephone-office power-supply sources.

Fig. 39 shows a high-frequency bridge of the differential-transformer type with a normal operating range covering that of the oscillator above mentioned, and capable of an accuracy throughout this range of one-quarter of one per cent.

Fig. 40 shows a high-frequency detector unit for

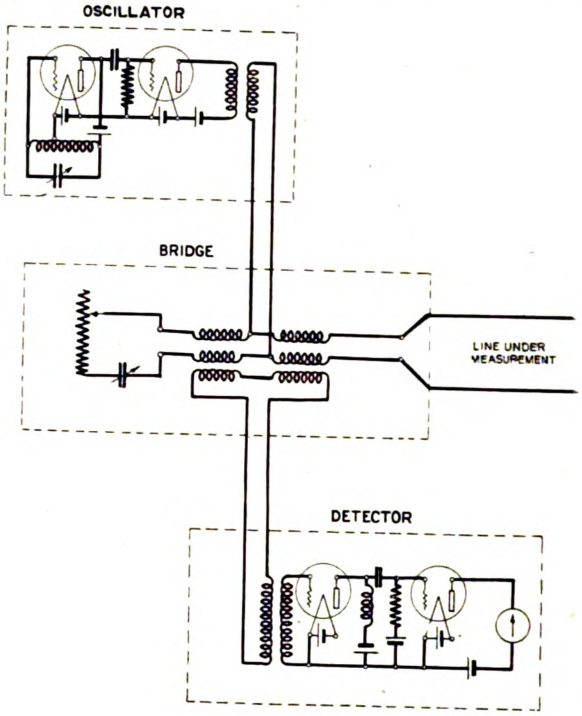

Fig. 41

use in bridge measurements. This involves the use of several vacuum tubes in an amplifier-detector circuit with an optional detecting arrangement allowing either:

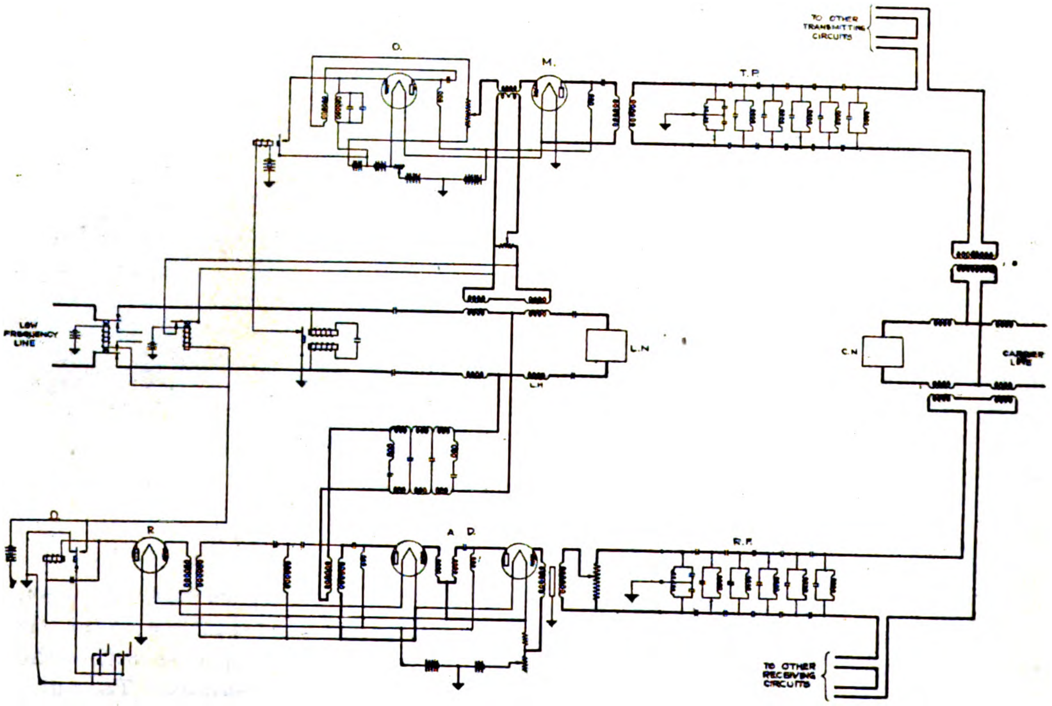

Fig. 42

a. Recording on a direct-current galvanometer, or
b. The use of a telephone receiver.

Attenuation measurements have been carried out largely by the use of thermocouple meter circuits in conjunction with an oscillator of the general type above mentioned. This permits measuring directly the attenuations of lines up to about 250 miles in length. The current sent into the line is compared with the corresponding received current, with the circuit properly terminated. An over-all accuracy of about 1 per cent is usually obtained. Currents as low as 0.25 milliampere may be read with this method thus making it possible to measure attenuations involving current ratios up to 1:200, or a line length equivalent to approximately 50 miles of standard cable. For greater lengths of line, circuits involving the use of the sensitive detector circuit above mentioned have been employed using comparison methods.

Impedance measurements are made with the oscillator, bridge and detector circuits above noted. A schematic circuit arrangement is shown on Fig. 41.

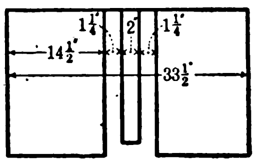
Longitudinal and Transverse Heat Flow in Slot-Wound Armature Coils

BY CARL J. FECHHEIMER
Research Engineer, Westinghouse Elec. & Mfg. Co.

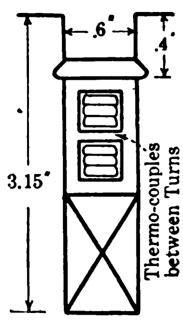
(Concluded from page 340 of JOURNAL for April 1921.)

Calculations by Equations and Test Results

In order to check the equations derived, thermocouples were placed in the armature (stator) coils of a 2400-volts, three-phase, 60-cycle, 3600-rev. per min., turbo generator. The following are the proportions of the generator:



Length of core $33\frac{1}{2}$ inches.
Number of slots 48.
Size of slot 0.6 in $\times$ 3.15 in.
Number of conductors per slot $= 4$ ($N = 2$).
Size of conductor = three 0.144 in. by 0.325 in.
Connection one circuit star.
Throw of coils, slot 1 to slot 13.
Approx. length of ¼ mean turn = 32.5 in.



Currents in upper coils in which thermocouples were embedded were out of phase by 120 electrical degrees with currents in coils in bottom of slot.

The ends of the coils were separated from one another between layers as well as circumferentially. The cooling surface was therefore taken as the perimeter of the coil (per inch longitudinally).

Thermocouples were also placed in the iron, about half-way down the tooth. The temperatures rises in the iron are shown in Fig. 7 for distribution of temperatures axially.

It will be seen that the temperature distribution in the iron is nearly that of a parabola, if the origin for x be taken as the end of the radial duct near the vertical center line, thus making L_e 14 ½ inches.

Embedded Portion

D_a = Insulation thickness $= \dfrac{0.6 \text{ in.} - 0.325 \text{ in.}}{2} =$ 0.138 in.

Gaged size of outside of coil = 0.549 in. by 1.197 in.

Outside surface of two sides plus width = 1.197 in. $\times$ 2 + 0.549 in. = 2.943 in.

Bare Copper surface = 0.144 in. $\times$ 12 + 0.325 in = 2.05 in.

Q_e = Average of above = 2.5 sq. in. (one inch axially)

ϵ_e = Eddy factor for upper coil = 1.092.[10]

ϵ_e = Eddy factor for lower coil = 1.065.

To avoid figuring twice, with so small difference in loss the eddy factor has been taken as 1.08 = ϵ_a.

k_e = thermal conductivity taken as 0.0025 watts per sq. in. per in. per deg. cent.[11]

L_e = length of embedded portion considered = 14.5 in.

End Windings

Gage size of ends = 0.57 in. by 1.28 in.

Q' = external surface = 2 (0.57 in. + 1.28 in.) = 37. sq. in.

---

10. Figured by formula in paper by R. E. Gilman, "Eddy Current Losses in Armature Conductors." A. I. E. E. June, 1920.

11. Data on transverse thermal conductivity of coil wrappers consisting of cement paper and mica are given in article by T. S. Taylor in *Electrical World* for Feb. 14, 1920 as about 0.00245 for 6600 volts. Any figure must be regarded as approximate. The low values are largely due to contact resistance between layers of insulation.

Internal surfaces = 0.144 in. × 12 + 0.325 in. × 2 = 2.48 sq. in.

Q_b = average of 3.7 and 2.48 = 3.1 sq. in.

D_b = insulation thickness = $\dfrac{0.57 \text{ in.} - 0.325 \text{ in.}}{2}$ = 0.122 in.

ϵ_b = eddy current factor for ends = 1.03

k_b = thermal conductivity of ends taken as 0.0035 watts, per inch per sq. in. per deg. cent.[12]

k' = emissivity from coil-end surfaces taken as 0.045 watts, per sq. in. per deg. cent.[13]

L_b = length from end of core to end of winding = 15.75 in.

General Data

k_c = thermal conductivity of copper taken as 9 watts per sq. in. per in. per deg. cent.

q = cross-section of conductor = 0.138 sq. in.

θ_0 = air temperature around coil ends in test = 30.7 deg. cent.

Average ingoing air temperature = 23.7 deg. cent.

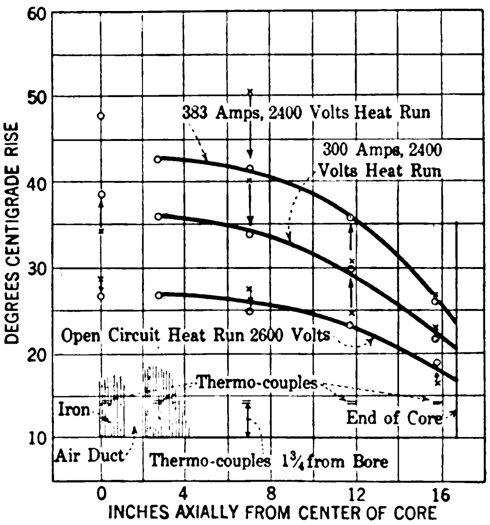


FIG. 7—CURVES SHOWING VARIATION OF TEMPERATURE RISES OF IRON (AXIALLY)

Heat Run at 300 *Ampere,* 2400 *Volts*

$$I^2 r = \frac{\rho N I^2}{q} = \frac{0.625 \times 2 \times 300^2}{10^6 \times 0.138} = 0.818 \text{ watt.}$$

$$K_a = \frac{k_a Q_a}{D_a} = \frac{0.0025 \times 2.5}{0.138} = 0.0453.$$

$$K_b = \frac{k_b Q_b}{D_b} = \frac{0.0035 \times 3.1}{0.122} = 0.089.$$

12. From unpublished data on transverse thermal conductivity of varnished cambric and linen tape used on ends.

13. From unpublished data. See some data and description of tests, by T. S. Taylor in A. S. M. E. *Journal*, April 1920.

$$\gamma = \frac{1}{1 + \dfrac{0.089}{0.045 \times 3.7}} = 0.652 \text{ (equation (\textbf{16})}.$$

From Fig. 7, $\theta_m = 36.3 + 23.7 = 60°$ $(x = 0)$

From Fig. 7, $\theta_i = 20.5 + 23.7 = 44.2$ for $x = L_a = 14.5$ in.

Assuming parabolic distribution of tooth temperatures, from equation (**53**),

$$f = \frac{x^2}{1 - \dfrac{\theta_i}{\theta_m}} = \frac{\overline{14.5}^2}{1 - \dfrac{44.2}{60}} = 800$$

This value for f gives very close agreement between the iron temperature curve figured from equation (**53**) and test.

$$\theta_i = 60\left(1 - \frac{x^2}{800}\right)$$

Calculations for Constant Iron Temperature

Figuring on basis of constant iron temperature, the average iron temperature is:

$$\frac{1}{14.5}\int_{x=0}^{x=14.5} \theta_i \, d x = \frac{1}{14.5}\int_0^{14.5} 60\left(1 - \frac{x^2}{800}\right) d x = 54.75 \text{ deg.}$$

$$\theta_{a0} = \frac{B_a}{A_a} = \frac{0.0453 \times 54.75 - 1.08 \times .818}{0.0453 - 1.08 \times 0.818 \times 0.00427}$$

$$= \frac{3.364}{0.04152} = 81 \text{ deg. (Eq. \textbf{13})}.$$

$$A_a = \frac{0.04152}{9 \times 2 \times 0.138} = 0.06172; \sqrt{A_a} = 0.1292$$

(Eq. **7**)

$\sqrt{A_a}\, L_a = 0.1292 \times 14.5 = 1.876$

Tanh 1.876 = 0.953

Cosh 1.876 = 3.33

Values of the hyperbolic functions may be read from Fig. 8.

$$\theta_{b0} = \frac{B_b}{A_b}$$

$$= \frac{0.652 \times 0.089 \times 30.7 + 1.03 \times 0.818}{0.0652 \times 0.089 - 1.03 \times 0.818 \times 0.00427}$$

$$= \frac{2.63}{0.0545} = 48.3 \text{ deg.} \quad \text{(Eq. \textbf{27}.)}$$

$$A_b = \frac{0.0545}{9 \times 2 \times 0.138} = 0.02192; \sqrt{A_b} = 0.148$$

(Eq. **22**).

$\sqrt{A_b}\, L_b = 2.335$

Tanh 2.335 = 0.98

Cosh 2.335 = 5.2

$$\beta = \frac{0.148 \times 0.98}{0.1292 \times 0.953} = 1.178 \text{ (Eq. } \mathbf{28a}\text{)}.$$

$$\theta_L = \frac{81 + 48.3 \times 1.178}{1 + 1.178} = 63.4 \text{ degrees (Eq. } \mathbf{29}\text{)}$$

$$\theta_a = 81 - \left(\frac{81 - 63.4}{3.33}\right) \cosh (0.1292\, x)$$

$$= 81 - 5.29 \cosh \ (0.1292\, x) \text{ (Eq. } \mathbf{11}\text{)}.$$

$$\theta_{max} = 81 - 5.29 = 75.71 \text{ degrees, or 52 degrees rise.}$$

$$\theta_b = 48.3 + \left(\frac{63.4 - 48.3}{5.2}\right) \cosh (0.148\, y)$$

$$= 48.3 + 2.9 \cosh (0.148\, y) \text{ (Eq. } \mathbf{25}\text{)}.$$

$$\theta_{min} = 48.3 + 2.9 = 51.2 \text{ degrees or 27.5 degrees rise.}$$

The solid curves in Fig. 9, were figured from the above equations for θ_a and θ_b, allowing for the in-

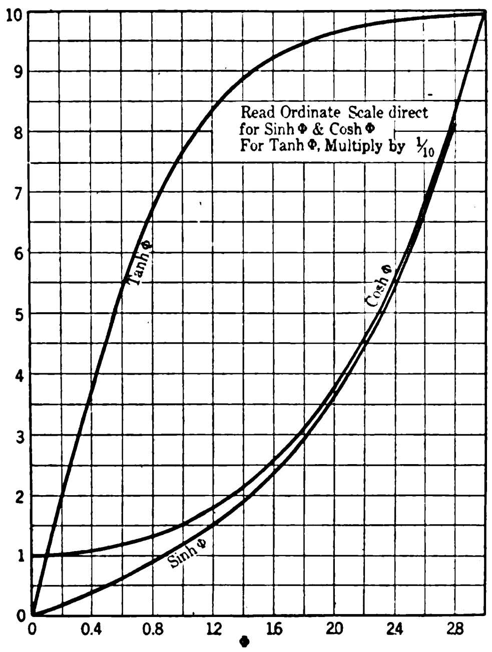

FIG. 8

going air temperature of 23.7 degrees. Using equation (33),

$$\theta_{av} = \frac{1}{30.25}\left[81 \times 14.5 + 48.3 \times 15.75 + \frac{81 - 48.3}{1 + 1.178}\left(\frac{0.98}{0.148} - \frac{1.178 \times 0.953}{0.1292}\right)\right]$$

$$= 62.9 \text{ deg., or 39.2 deg. rise.}$$

The 39.2 deg. average rise applied to 30.25 in. of coil length, which is 2.25 in. less than the quarter length of the mean turn, since the zero point of reference was taken at the end of iron adjacent to the radial vent duct near the vertical center line. If the temperature for those 2.25 in. be taken to be the same as the maximum (θ_{max} calculated = 52 deg. rise), the average temperature should be,

$$\frac{39.2 \text{ deg.} \times 30.25 \text{ in.} + 52 \text{ deg.} \times 2.25 \text{ in.}}{32.5 \text{ in.}}$$

$$= 40.1 \text{ deg. rise.}$$

The temperature rise measured by resistance as soon as possible after shut down was 35.3 deg., the difference being due at least in part, to the cooling of the winding before the resistance could be measured.

The average temperature in the embedded portion by equation (**33a**) is 48.3 deg. rise. Allowing for the 2.25 in. at 52 deg. rise, this average rise becomes 48.8 deg. rise.

Calculations for Parabolic Variation in Iron Temperature

The constants are the same as for constant core temperature.

$k_c = 9$, $q = 0.138$, $N = 2$, $I^2 R = 0.818$, $D_a = 0.138$, $Q_a = 2.5$, $\epsilon_a = 1.08$, $k_a = 0.0025$, $L_a = 14.5$, $K_a = 0.0453$, $D_b = 0.122$, $Q_b = 3.1$, $\epsilon_b = 1.03$, $k_b = 0.0035$, $L_b = 15.75$, $K_b = 0.089$, $Q' = 3.7$, $k' = 0.045$, $\gamma = 0.652$, $f = 800$, $\theta_m = 60$, $\theta_0 = 30.7$. $A_a = 0.01672$, $\sqrt{A_a} = 0.1292$, $\sqrt{A_a}\, L_a = 1{,}876$, $\tanh 1.876 = 0.953$, $\cosh 1.876 = 3.33$, $A_b = 0.02192$, $\sqrt{A_b} = 0.148$, $\sqrt{A_b}\, L_b = 2.335$, $\tanh 2.335 = 0.98$, $\cosh 2.335 = 5.2$.

$$\text{Then } H = \frac{60 \times 0.0453}{800 \times 9 \times 2 \times 0.138} = 0.00136 \text{ (Eq. } \mathbf{57}\text{)}$$

$$\theta_{a0} = \frac{B_a}{A_a} = \frac{0.0453 \times 60 + 1.08 \times 0.818}{0.0453 - 1.08 \times 0.818 \times 0.00427}$$

$$= \frac{3.604}{.04152} = 86.7 \text{ deg. (or 63 deg. rise).}$$

For end windings, $\theta_{b0} = 48.3$, and $\beta = 1.178$ as previously.

$$\theta_L = \frac{1}{1 + 1.178}\left[86.7 + 1.178 \times 48.3 - \frac{0.00136}{0.1672}\left(\overline{14.5}^2 + \frac{2}{0.01672} - \frac{2 \times 14.5}{0.1292 \times 0.953}\right)\right]$$

$$= 62.6 \text{ deg. (Eq. } \mathbf{62}\text{) or 38.9 deg. rise.}$$

$$\theta_a = 86.7 - \frac{0.00136}{0.01672}\, x^2 - \frac{2 \times 0.00136}{(0.01672)^2} - \frac{1}{3.33}\left[86.7 - 62.6 + \frac{0.00136}{0.1672} \times \overline{14.5}^2 + \frac{2 \times 0.00136}{(0.01672)^2}\right] \cosh (0.1292\, x)$$

$$= 77 - 0.0813\, x^2 + 0.81 \cosh (0.1292\, x) \text{ (Eq. } \mathbf{60}\text{)}.$$

For $x = 0$, $\theta_{max} = 77.8$ or 54.1 deg. rise

$$\theta_b = 48.3 + \left(\frac{62.6 - 48.3}{5.2} \right) \cosh (0.148\, y)$$

$$= 48.3 + 2.76 \cosh (0.148\, y) \quad \text{(Eq. 52)}$$

For $y = 0$, $\theta_{min} = 51.1$ or 27.4 deg. rise.

The points calculated from the above for θ_a and θ_b will be found plotted in Fig. 9. As will be seen there is comparatively little difference between the curves for constant core temperature and for parabolic core temperature. In fact there is so little difference that

$$\theta_{max} = \frac{\dfrac{1}{0.00427} + 63.4}{\cos \left(2175 \times 14.5 \sqrt{\dfrac{1.08 \times 0.625 \times 0.00427}{10^6 \times 9}} \right)} - \frac{1}{0.00427} = 119 \text{ deg. or } 95.3 \text{ deg. rise.}$$

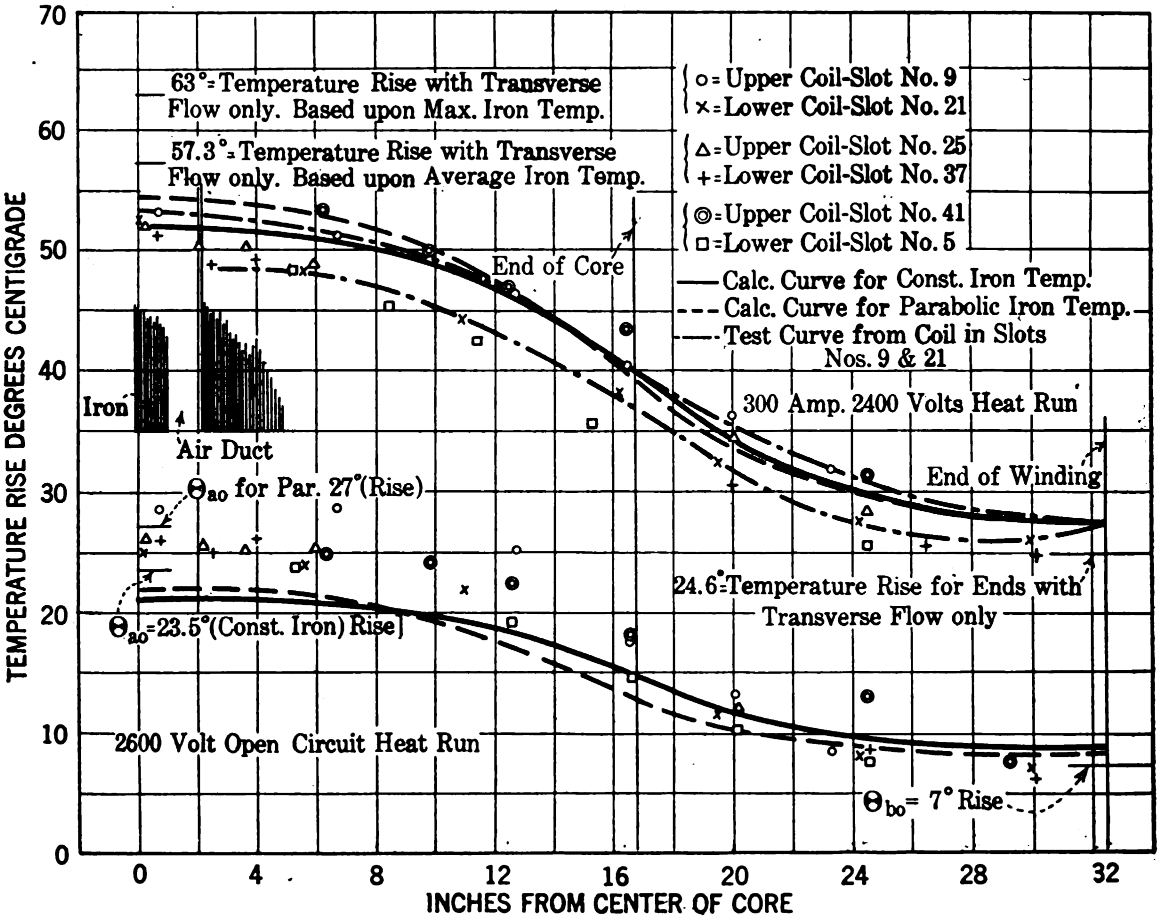

FIG. 9

it is questionable which is in closer agreement with the test points. In the calculations which follow, the constant core temperature figures are, n general, used.

Numerical Calculations Using Supplementary Equations

If equation (36) is employed, which assumes only longitudinal flow without allowing for the temperature coefficient, and if $\theta_L = 63.4$ deg., (as computed for constant core temperature, and if $\rho = \dfrac{0.825}{10^6}$ corresponding to 75 deg.,

$$\theta_{max} = 63.4 + \frac{1.08 \times 0.825 \times 2175^2 \times 14.5^2}{9 \times 2}$$

$$= 112.4 \text{ deg. total, or } 88.7 \text{ deg. rise.}$$

If equation (37) is used, which also assumes only longitudinal flow, but allows for the temperature coefficient,

Had k_c been taken as $(2.54 \times 3 =)$ 7.6 as in paper by Symonds and Walker, the temperature rise by same formula would have been 121 degrees; by Symonds and Walker's formula, the rise is 98.3 degrees. Or, using $k_c = 9$ in Symonds and Walker's formula, the rise is 87.3 degrees.

A comparison of these results is given in the following table:

TABLE I.

Maximum temperature rises by various means:

Longitudinal flow only				Transverse flow only		Combined flow		Test
Equa. No. 36	Equa. No. 37	Symond & Walker formula $k_c = 7.6$	Symond & Walker formula $k_c = 9$	Const. Core Temp.	Parabolic Core Temp.	Const. Core Temp.	Par. Core Temp.	
88.7	95.3	98.3	87.3	57.3	63	52	54.1	50.5 to 53.2

It should be noted that neglect of the transverse heat flow may lead to very considerable errors; even in a machine of medium core length the error introduced by considering only the longitudinal flow is very great, and in longer machines the error is even greater. Also, if the iron temperature be taken at its maximum value and the longitudinal flow be neglected, the calculated rise is 63 degrees; or there was an error, even in this machine of moderate length of core of about 11 degrees, or 21 per cent. If the longitudinal flow be neglected, and the average iron temperature be considered, the error in this particular machine or perhaps in longer machines is not very great. But it would be dangerous to draw any general conclusions, for as is pointed out in another part of this paper, under the subject of Eddy Currents, even in certain rather long machines, and certainly in short machines, the longitudinal flow has very material influence upon the maximum temperature. On the other hand, the close agreement of the maximum temperatures calculated either by means of the equation for constant core temperature or by the equation for parabolic core temperature with the test results shows the possibilities of estimating the maximum temperature by means of the equations derived in this paper.

The calculated temperature of the external surface of the end windings is given by equation (**38**), while the machine is in operation. Substituting in that equation,

$$\theta_e = \frac{0.089\ \theta_b + 0.045 \times 3.7 \times 30.7}{0.089 + 0.045 \times 3.7} = 0.349\ \theta_b + 20.2 \text{ deg.}$$

(The ingoing air temperature (23.7) deg.) must be deducted to secure rise).

Taking θ_b as the average of the two calculated curves in Fig. 9, (there are very slight differences), a comparison of calculated and test is given in Table II.

TABLE II

Distance along Copper from Center of Core	θ_b (Rise)	Calc. θ_e (Rise)	Test θ_e (Rise)
22.25	31.2	15.7	11.25
23.25	30.5	15.2	10.25
24	30	15.0	8.25

The test figure of 11.25 deg. is the average of three readings: 7.25, 9.75, and 16.75 deg. The lower temperatures by thermometer are probably largely due to the influence of the air striking the pad over the bulb of the thermometer, thereby lowering its reading. All engineers agree upon the inaccuracy of this method of judging temperatures.

The losses and the quantities of heat dissipated will now be accounted for. From equations **39a**, **40a** and **41a** calling $X = L_a$, and using figures for constant iron temperature.

$$(W_2)_a = \frac{9 \times 2 \times 0.138 \times 0.1292 \times 1.178\ (81-48.3) \times 0.953}{1 + 1.178} = 5.4 \text{ watts.}$$

$$(W_1)_a = 0.0453 \left[(81 - 54.75)\ 14.5 - \frac{(81 - 48.3)\ 1.178}{0.1292\ (1 + 1.178)} \times 0.953 \right] = 11.32 \text{ watts.}$$

$$(W)_a = 1.08 \times 0.818 \left[(1 + 0.00427 \times 81)\ 14.5 - \frac{0.00427\ (81 - 48.3)}{0.1292} \times \frac{1.178}{1 + 1.178} \times 0.953 \right] = 16.72 \text{ watts.}$$

Thus, in the embedded portion, the total watts generated (16.72) equal the watts dissipated by transverse flow (11.32) plus the watts flowing to the ends at $X = L_a$ (5.4). See eq. (**1**)).

Similarly, by substituting in equations **38b**, **40b** and **41b**.

$$(W_2)_b = 5.4 \text{ watts.}$$
$$(W_1)_b = 21.8 \text{ watts.}$$
$$(W)_b = 16.4 \text{ watts.}$$

Thus, the total watts dissipated from the end (21.8 watts) = the watts generated in the ends (16.4 watts) plus the watts received from the embedded portion (5.4 watts). (See eq. (**19**)). Note also the agreement between $(W_2)_a$ and $(W_2)_b$.

Another interesting check is that based on the total wattage. It was previously found that the average temperature for the 30.25 in. considered was 62.9 deg., so that the average watts per inch

= (1 + 0.00427 × 62.9) 0.818 = 1.039 exclusive of eddy loss. The average eddy factor is,

$$\frac{1.08 \times 14.5 \text{ in.} + 1.03 \times 15.75 \text{ in.}}{30.25 \text{ in.}} = 1.054.$$

Thus, the total loss for the 30.25 in.

$$= 1.039 \times 1.054 \times 30.25 = 33.15 \text{ watts.}$$

From the previous calculations, the loss

$$= 16.72 + 16.4 = 33.12 \text{ watts.}$$

The rate of generation of heat in the embedded portion is,

$$\frac{d\,w}{d\,x} = 1.08 \times 0.818\ (1 + 0.00427\ \theta_a)$$

For θ_a = 75.7 degrees (that is for $X = 0$),

$$\frac{d\,w}{d\,x} = 1.17 \text{ watts per inch.}$$

For $\theta_a = 63.4$ degrees ($X = L_a$),

$$\frac{d\,w}{d\,x} = 1.12 \text{ watts per inch.}$$

In the ends, $\dfrac{d\,w}{d\,y} = 1.07$ watts per inch for $y = L_b$.

In the ends, $\dfrac{d\,w}{d\,y} = 1.03$ watts per inch for $y = 0$.

The average rate of generation of heat in the embedded portion is

$$\frac{16.72 \text{ watts}}{14.5 \text{ in.}} = 1.15 \text{ watts per inch.}$$

$$\frac{d\,w_1}{d\,x} = K_a\ (\theta_a - \theta_i)$$

$= 0.95$ watts per inch for $X = 0$

$= 0.392$ watts per inch for $X = L_a$ (end of core).

The average $= \dfrac{11.32 \text{ watts}}{14.5 \text{ in.}} = 0.78$ watts per inch.

For the ends,

$$\left(\frac{d\,w_1}{d\,y}\right) = \gamma\, K_b\, (\theta_b - \theta_0)$$

$= 1.89$ watts per in. for $y = L_b$ (end of core).

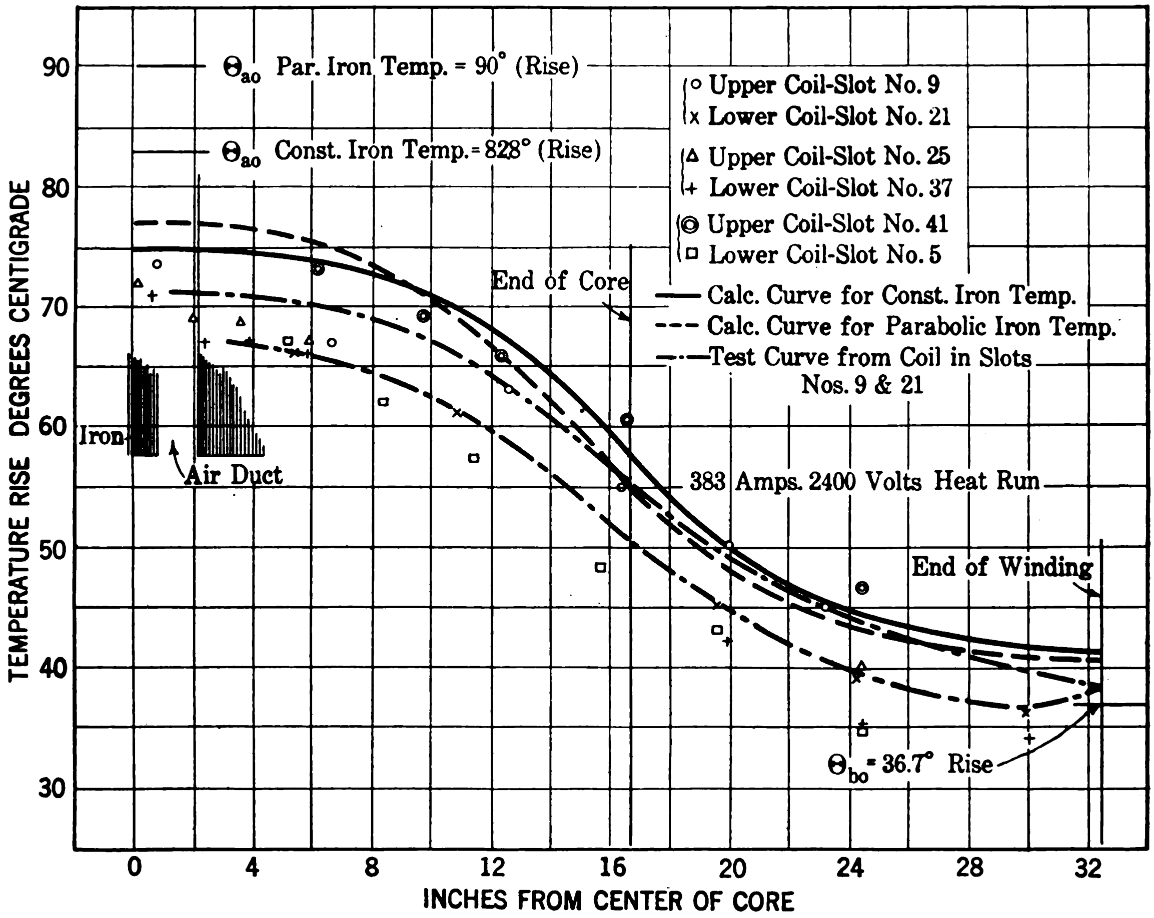

Fig. 10

The average for the ends is

$$\frac{16.4}{15.75} = 1.04 \text{ watts per inch.}$$

In accordance with the method of calculating eddy current loss, there is an abrupt change at the end of the core, and therefore the rate of generation of loss changes abruptly there also; that is, from 1.12 to 1.07 watts per inch. This abrupt change is more noticeable in machines with high-eddy current loss in the copper. The figures for watts per inch given above are the maxima and minima for the embedded and end portions.

The transverse rate of flow of heat in the embedded portion is,

$= 1.19$ watts per in. for $y = 0$ (end of winding).

The average $= \dfrac{21.8}{15.75} = 1.384$ watts per inch.

Thus, the maximum rate of transverse flow (and therefore of heat dissipation) is, in this particular case, about twice as great from the ends as from the embedded portion, and there is a very great change when passing from the embedded to the end winding portion.

The longitudinal flow is maximum at the end of the core (5.4 watts) and is zero for $X = 0$, and for $Y = 0$. Its relative values at any points can be determined from

the slope of the curve for temperature in Fig. 9, or may be obtained by substituting in equations (**39a**) and (**39b**).

Comments on Tests and Calculations

In addition to the tests made with 300-ampere load, and plotted in Fig. 9, tests were also made at no-load, open circuit at 2600 volts (Fig. 9), and with 383 amperes, 2400 volts, nearly zero power-factor, plotted in Fig. 10. The same constants, such as thermal conductivity, emissivity from the end windings, areas for transverse flow, etc., were used in the no-

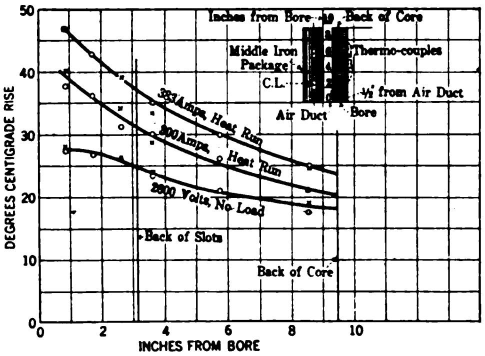

Fig. 11—Curves Showing Variation of Temperature Rises, Radially in the Iron

load and 383-amp. calculations as for the 300 ampere load calculations, with the exception that the eddy loss constant for the 383 amp. curves was taken slightly lower than for 300 amperes because the temperature was higher.

In Fig. 11 will be found some curves showing iron temperatures radially. They were measured 0.5 in. from one of the radial vent ducts. There is an unmistakable drop in temperature from the bore outward. The axial temperatures were measured 1¾ in. from the bore (Fig. 7), or a little more than half way down the tooth. The calculated curves in Figs. 9 and 10 were based upon the measured axial iron temperatures plotted in Fig. 7. The difference in tooth temperatures for the different depths undoubtedly explains much of the difference between the copper temperatures in the upper and lower coils. The constants used in the calculations were of such values as to give quite close agreement with the test curves for the upper coils. A comparison of Figs. 9 and 10 with Fig. 11 will show nearly the same difference in maximum temperature between the upper and lower coils as there was between the tooth temperatures for the corresponding regions.

One of the principal differences between test and calculation appears in the no-load curve (Fig 9). Evidently, with no I^2R and eddy current loss in the copper, some heat from the iron flows transversely from the iron to the copper, and is transmitted longitudinally to the coil-ends where it again flows transversely to the coil surfaces, and is taken up there by the air. In order for heat to flow from the iron to the copper, the copper must be at the lower temperature; this appears in the calculated curves. (See Figs. 7 and 9). On the other hand the test data plotted in Fig. 9 for the no load heat run, show maximum temperature rise of 28.5 deg. for the copper, whereas the maximum iron temperature (by curve) from Fig. 7 was 27.5 deg. rise. Since the large number of couples embedded in the iron necessitated the placing of them in various teeth, in all probability the iron temperatures used for calculating the curves in the no-load curve in Fig. 9 were lower than some of the iron temperatures adjacent to the coils. This statement is further proved by the fact that in Fig. 7 some of the test points were not on the curves as drawn.

The 383-amperes calculated curves (Fig. 10) show slightly higher temperatures than most of the test points. The slight increase in thermal conductivity of the insulation with the higher temperatures then obtaining but which were not allowed for in the calculations, may explain some of these differences.

For convenience, in Table III the principal points of interest are recorded. Attention is called to the close agreement between calculations and test for maximum temperature, minimum temperature and temperature at the end of the core; the exception being the maximum temperature at no-load. It will further be noted that there is but slight difference between the calculated minimum temperature, considering transverse flow only, and the minimum temperature by test. On the other hand there may be quite a large difference between the calculated maximum temperature,

TABLE III.

considering transverse flow only, and the maximum test temperature; especially is this the case at the 383-ampere load test when the temperature is figured on the basis of the maximum iron temperature (90 deg.) instead of 73.5 deg. rise). And this applies even though the machine is of medium length, and the copper,

at this load was worked at the fairly high nominal density of 2780 amperes per sq. in., with nearly negligible eddy current loss. (See the second paragraph under subject "Eddy Currents"). Thus, it may be misleading even in medium length machines, to ignore the longitudinal flow.

Further comparisons will be found under "The Average Coil Temperatures."

THE AVERAGE COIL TEMPERATURE

The temperature of the winding measured by resistance after shut-down is the average temperature at the particular time of measurement. Owing to the fact that there is necessarily a lapse of time between the removal of the load and the measurement of resistance, and since there is usually a difference in temperature between the copper and surrounding iron or air (the copper being usually at higher temperature), there is necessarily heat flow after shut-down and before the resistance is measured. Consequently, the average temeperature at the end of the heat run is usually higher than measured. At no-load the average temperature of the winding at the end of the run may be lower than the measured temperature, owing to the winding being at lower temperature than the iron.

Equation (**33**) enables the calculation of the average temperature (based upon constant iron temperature); with the use of equation (**33a**) the average temperature of the embedded part may be calculated. The results for the three heat runs are given in Table IV.

TABLE IV.

Heat Run	2600 Volt, N. L.	2400 V., 300 Amp.	2400 V., 383 Amp.
Calc. Av. Temp. Rise Embedded Part.	19.3	48.9	70.4
Calc. Av. Temp. Rise Entire Winding.	14.9	40.1	58.3
Av. Temp. Rise Test. (Res. Meas.)	15.5	35.3	44
Max. Temp. Rise Test. (Slot No. 9.)	28.5	53.3	73.5

An especial effort was made in these tests to allow as little time as possible to elapse between shut-down and measurement of resistance. (A Kelvin bridge was used). It will be noted, from an inspection of Table IV that the calculated average temperatures for both load runs were higher than test, whereas at no-load the reverse is the case, although the difference is slight.

Referring to Fig. 9, the average of the 300-ampere test curves for slots 9 and 21 (average of upper and lower curves) is 39 deg. rise, which is only 1.1 deg. lower than the calculated rise (40.1 deg.) The temperature rise by resistance was 35.3 degrees or 3.7 degrees lower than the test average rise. This difference is undoubtedly largely due to error in measurement due to loss of time.

The average rise from test curves on Fig. 10, (383-amperes load), as found by averaging the test curves for the coil in slots 9 and 21, is 54.1 degrees. The calculated average from the calculated curve is 58.3 deg., a difference of 4.2 deg. The temperature rise measured by resistance was 44 deg., or 10.1 deg. lower than actual. Thus there was an error, probably due to loss of time, of 23 per cent. It will therefore appear that the average temperatures as determined by resistance are not reliable.

The figures in Table IV show that the average temperature rise determined by resistance is certainly no means of judging the average temperature of the embedded part of the winding. Thus, in the 300-ampere run, if 1.1 deg. are deducted from the calculated rise $(48.9 - 1.1)$ to allow for the difference between the calculations and test, then the difference between the average embedded copper temperature rise and the measured average temperature rise of the entire winding is $(47.8 - 35.3 =) 12.5$ deg. At the higher load the difference is approximately $[(70.4 - 4.2) - 44 =]$ 22.2 deg. or about 50 per cent of the measured temperature rise. Certainly the resistance measurement affords no means of judging the maximum temperature, and an inspection of Table IV is sufficient proof of that statement without further comment.

THE INFLUENCE OF THE CORE LENGTH

It is felt that a paper on longitudinal and transverse heat flow would not be complete without illustrating the influence of core length upon temperatures, thereby helping to clarify the physical picture. It is believed that further assistance is obtained by showing the influence of the core length upon the watts generated, the watts transmitted transversely, and the watts transmitted longitudinally. It must be borne in mind that one set of curves of this character are not of general application, but to obviate this, sets of curves for various proportions of slots, copper section, insulation thickness, current density, etc., could be worked out, if believed to be sufficiently useful.

The particular proportions adopted were those of the turbo generator, for which the tests and calculations are given in this paper. The particular load selected was the one for 300 amperes 2400 volts. The conditions for constant average iron temperature of same value as in other calculations were assumed. Inasmuch as, in laying out a line of machines, it is usual to have some relation between pole pitch and core length, and since the length of the coil end is proportional to the pole pitch, the ratio of length of coil end to embedded portion was taken to be constant. Such assumption is not generally justifiable; as for instance, with changing length, (and proportionate diameter) the cooling of the end windings must also change (their cooling rate was taken to be constant); with increasing diameters the peripheral speed in such ma-

chine would eventually become prohibitive; and in commercial practise the length of core is frequently changed without changing the diameter.

In Fig. 12 will be found "Curves Illustrating the Influence of Core Length upon Temperature Rise." The particular machine described in this paper has a

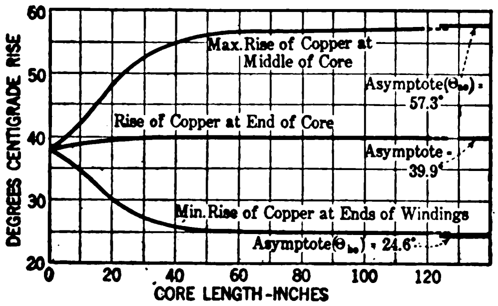

Fig. 12—Curves Illustrating Influence of Core Length Upon Temperature Rise

Based on constant ratio of length of ends to embedded parts.

nominal core length of (2× 14½ =) 29 in. as plotted in these curves. For these proportions, there is practically no change in temperature if the core length is increased beyond 50 in.

In Fig. 13 are plotted curves illustrating the losses

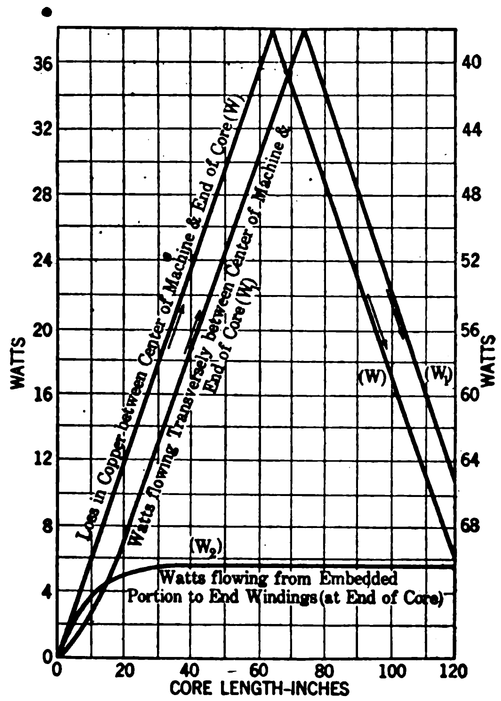

Fig. 13—Curves Illustrating the Losses in One-Half of the Embedded Portion of One Coil, and the Heat Paths for Same

Based on constant ratio of length of ends to embedded part.

in one half of the embedded portion of one coil, and the heat paths for same. Thus, for very short core lengths, most of the heat flows longitudinally, to be dissipated from the ends; for about 7-in. length of core about twice as much heat flows longitudinally as flows transversely; for 16-in. length the same quantities flow along the two paths; and beyond that, the longitudinal heat flow increases but little, whereas the transverse flow increases indefinitely. The total watts must always be the sum of the transverse and longitudinal flows, at any given length of core, and

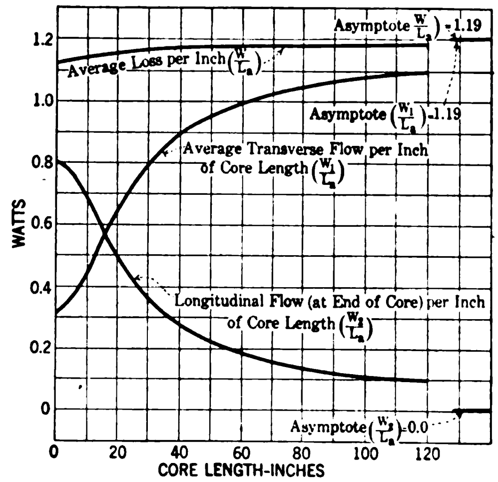

Fig. 14—Curves Illustrating the Losses in One Armature Coil and the Heat Paths per Inch of Core Length

Based on constant ratio of length of ends to embedded part.

would be directly proportional to the core length, but for the influence of temperature increasing the rate of loss generation.

In Fig. 14 the average rates of heat generation and the heat flows per inch of core length are plotted as functions of the core length. These curves of longitudinal and transverse flows illustrate the "usefulness" of the two for dissipating the generated heat; thus, as is well-known, the influence of the longitudinal

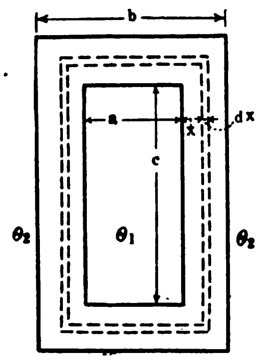

Fig. 15

flow is of maximum benefit for zero core length, and rapidly diminishes until for infinite length it becomes zero. The transverse flow is of minimum benefit for zero core length and approaches the same asymptote as the total generated watts approach; that is for infinite length all of the watts flow transversely.

APPENDIX

Area for Transverse Flow

Let Fig. 15 represent the section of a coil, the

single insulating wall being $\frac{b-a}{2}$. If W is the wattage flowing transversely, k the thermal conductivity $d\,\theta$ the temperature drop through small thickness $d\,x$, and the area of flow is $2\,[(a+2\,x)+(c+2\,x)]$, then:

$$W = -\,k\,2\,(a+c+4\,x)\frac{d\,\theta}{d\,x}$$

The negative sign appears because θ decreases with increasing x. Then:

$$\int_{\theta=\theta_1}^{\theta=\theta_2} d\,\theta = -\frac{W}{2\,k}\int_{x=0}^{x=\frac{b-a}{2}}\frac{d\,x}{a+c+4\,x}$$

$$(\theta_1-\theta_2) = \frac{W}{8\,k}\log_e(a+c+4x)\Big]_0^{\frac{1}{2}(b-a)}$$

$$= 0.288\;\frac{W}{k}\log_{10}\left(\frac{2\,b+c-a}{a+c}\right)$$

Now, figuring on *average* area basis,

$$W = k\left[2\left(a+\frac{b-a}{2}\right)+2\left(c+\frac{b-a}{2}\right)\right]\frac{\theta_1-\theta_2}{\frac{(b-a)}{2}}$$

Or,

$$(\theta_1-\theta_2) = \frac{W}{4\,k}\;\frac{(b-a)}{(b+c)}$$

Suppose the coil be intended for high voltage, and $a = 0.5$ in., $b = 1$ in., $c = 2$ in. By the more exact logarithmic expression, $(\theta_1-\theta_2) = 0.0419\frac{W}{k}$.

By the second, average area formula, $(\theta_1-\theta_2) = 0.0416\;\frac{W}{k}$. The difference is less than one per cent, thus justifying the use of the approximate equation. With thinner insulation, the error is less than with thick insulation.

AN OPPORTUNITY FOR COMMUNITY SERVICE BY PROFESSIONAL SOCIETIES

BY D. B. RUSHMORE AND R. F. EMERSON

The fundamental desire of individuals and organizations today is to render real service to the community of which they are a part. This is finding expression in many different forms and all over the country are being erected buildings of various kinds which have community service for their object. A large number of special organizations for this particular purpose are also coming into being.

There are however, many simple and easy ways in which existing means can be adapted to this end without special expensive buildings or special organizations and expense. Practically all of the large engineering professional societies in this country have local sections and have in the community many men who possess knowledge regarding science and engineering which is of great value and interest to the public if properly presented to them. Also most modern public schools have auditoriums or lecture rooms.

In connection with a plan which was proposed for Schenectady and which would involve a large building and the raising of a very considerable sum of money, it was felt by the authors that something could be done immediately to begin this work without waiting for any further developments.

A plan was devised whereby a series of lectures on science and engineering should be given to the public in simple, non-technical language under the auspices of the Schenectady Board of Education and the speakers furnished from the local sections of the American Chemical Society, Illuminating Engineering Society, American Society of Mechanical Engineers and the American Institute of Electrical Engineers.

As a result the following lectures were given:

November 29th, 1920, Chemistry and Some Common Things, by Prof. Edward Ellery.

December 13th, 1920, Light—Its Use and Abuse, in the Home, in the Street, and in the Place of Business, by S. L. E. Rose.

January 10th, 1921, Forty Years of Railroading, by S. T. Dodd.

January 24th, 1921, The X-Ray, by C. N. Moore.

January 24th, 1921, Submarine Detector Devices, by C. E. Eveleth.

March 14th, 1921, The Wonders of Electricity, by C. M. Ripley.

The first year's program has just been brought to a very successful end and it seems that such a valuable opportunity ought to be considered by all of the sections of the Institute and of other professional societies, and a great extension of this work should take place in the coming year. The attendance of the public showed that it greatly appreciated the opportunity to inform itself in connection with the various subjects presented and the experiment was, for a first try of this kind, unusually successful.

HIGH-VOLTAGE LIGHTNING ARRESTER TROUBLES

The Protective Devices Committee is making an attempt to learn of all unfavorable experiences which have occurred with all types of lightning arresters intended for normal operating voltage in excess of 7500 volts. It would like to get as full a statement as possible from all engineers regarding the defects of lightning arresters which they have in service and of their objections to the use of lightning arresters where such objections exist.

It would be of great assistance to the Committee if engineers having any information along this line would communicate with Mr. F. L. Hunt, Chairman, Subcommittee on Lightning Arresters, Turners Falls Power & Electric Co., Greenfield, Mass.

JOURNAL

of Electrical
Engineers

PUBLISHED MONTHLY BY THE A. I. E. E.
33 West 39th Street, New York
Under the Direction of the Publication Committee

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.
Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

A. I. E. E. ANNUAL MEETING

The 370th meeting of the A. I. E. E. will be held in the Engineering Societies Building, New York, May 20th, 1921. This is the Annual Meeting of the Institute, at which the result of the annual elections is announced and the report of the Board of Directors is presented.

Following the business meeting there will be a lecture by Dr. Albert W. Hull of the Research Laboratory of the General Electric Company, the subject of which will be, "The Magnetron: A New Electric Valve." The lecture will be accompanied by experimental demonstrations.

FUTURE SECTION MEETINGS

Cleveland.—May 17, 1921. Hotel Statler. Annual Dinner Meeting. Subject: "Some Recent Developments in Scientific Research." Speaker: Mr. C. F. Kettering, of The Dayton Engineering Laboratories.

Erie.—May 10, 1921. Subject: "Energy." Speaker: Dr. Charles P. Steinmetz.

Philadelphia.—May 9, 1921. "Celluloid Night," featuring the Spirograph.

San Francisco.—May 27, 1921. Subject: "220,000 Volt Transmission." This meeting will be in the nature of a symposium of results of studies and investigations by different speakers, and will also be descriptive of some of the equipment to be used for this transmission voltage now contemplated by two of the largest companies on the Pacific Coast. Professor Ryan will give the main paper.

Vancouver.—May 6, 1921. Subject: "Electric Power in Pulp and Paper Mills." Speaker: Mr. T. H. Crosby.

June 3, 1921. Annual Meeting. Election of officers.

Baltimore.—May 20, 1921. Subject: "Transformers". Speaker: Mr. J. T. Corrin, of the Pittsburgh Transformer Company. The meeting will be held in the new quarters of the Engineers Club in the Merchants & Manufacturers Building.

PITTSBURGH MEETING, APRIL 16, 1921

The joint meeting of the A. I. E. E. and the Association of Iron and Steel Electrical Engineers, which constituted the 369th meeting of the Institute, was held in Pittsburgh, in accordance with the announced program, on Saturday, April 16, 1921.

A special train conveyed about 800 members from the Union Station, Pittsburgh, to the Colfax Power Station of the Duquesne Light Company, arriving there about 11:00 a. m. Many other members reached the plant by motor.

Every facility for the inspection of every part of the plant, with or without guides, was afforded to the visiting members, after which a buffet luncheon was served to the entire party at the plant.

Afternoon Session

From the Power Station, all returned to Carnegie Hall, North Side, Pittsburgh, where the first technical session of the day was held at 3:00 p. m. Professor B. C. Dennison, Chairman of the Pittsburgh Section of the Institute, called the meeting to order and presented President Berresford as presiding officer; President E. S. Jefferies, of the A. I. & S. E. E., was also upon the platform.

After brief remarks, President Berresford called upon Messrs. C. W. E. Clarke and D. L. Galusha, of the Dwight P. Robinson Company, who presented their paper on "The Colfax Power Station of the Duquesne Light Company, Pittsburgh."

An interesting discussion followed, participated in by Messrs. C. S. Cook, G. F. Brown, F. C. Hanker, George Bell, C. F. Hirshfeld, F. Hodgkinson, W. T. Snyder, R. H. Keil, F. E. Leahy, E. C. Stone and the authors. Lack of time prevented further discussion but many others who had signified their intention to participate were requested to submit their discussion later for publication.

Dinner

An informal dinner, attended by over 700 members and guests of the two Societies, was held at the William Penn Hotel, at 6:00 o'clock p. m., at the close of which brief addresses were made by President Berresford of the Institute, President E. S. Jefferies of the A. I. & S. E. E., and President A. W. Thompson of the Philadelphia Company.

Evening Session

A second technical session followed immediately after the dinner, the presiding officer being President Jefferies of the A. I. & S. E. E. The papers presented were: "The Frequency Problem in the Steel Industry" by B. G. Lamme, Chief Engineer, Westinghouse Electric & Manufacturing Company; "The Interconnection of Steel Mill and Central Power Houses, and Its Relation to Frequency" by D. M. Petty of the Bethlehem Steel Company.

The discussion which followed was participated in by Messrs. R. B. Shover, James Farrington, L. F. Galbreith, Frank Leahy, A. C. Cummins, George E. Stoltz and the authors.

The entire meeting was enthusiastic and successful in every way, and reflects credit upon the joint committee of arrangements, consisting of representatives of both Societies.

SUNSET ON GREAT SALT LAKE

Annual and Pacific Coast Convention

SALT LAKE CITY, UTAH, JUNE 21-24, 1921

An unusual opportunity is offered Institute members this year to combine attendance at the Thirty-Seventh Annual Convention, Salt Lake City, Utah, June 21-24, 1921 with a pleasure sight-seeing trip among the natural wonders of the Yellowstone, the Grand Canyon, the Rockies and the Pacific Coast.

The Convention, itself, promises to exceed in interest previous annual meetings both from a technical viewpoint and as an opportunity to increase acquaintanceship among the members of the electrical engineering profession, and to renew acquaintance with old friends. The local arrangements at Salt Lake City provide a happy combination of business and recreation so adjusted that the inclinations of all may be satisfied. Twenty-four subcommittees, with their work directed and coordinated by the Convention Committee, H. T. Plumb, Chairman, insure careful attention to all necessary details. Arrangements to attend may be made with the full assurance that nothing has been overlooked to make this year's Convention a signal success. Ladies are particularly invited and will find the afternoon and evening events of particular interest.

Institute headquarters will be located at the Hotel Utah and all technical sessions will be held there.

An outline of the program follows:

Tuesday, June 21

The convention will open on Tuesday morning, June 21, with the Annual Presidential Address by Arthur W. Berresford. A technical session, with the presentation of several papers, under the auspices of the Electrical Machinery Committee will follow. Directly succeeding the technical session a luncheon for the Section Delegates is scheduled. This will serve as an opportunity for the delegates to become acquainted and to discuss points of general interest. Tuesday afternoon there will be a trip on foot past the most interesting historical Latter Day Saints buildings, followed by a short lecture and organ recital in the Tabernacle. At 7:00 p. m. an auto trip has been arranged to reach the famous Wasatch Boulevard at sunset and later to Capitol Hill. A return will be made to the Hotel Utah in time for an informal reception at 9:30 p. m.

Wednesday, June 22

Wednesday morning the second technical session will be held under the auspices of the Industrial and Domestic Power Committee. For the forenoon a special entertainment for the ladies has also been scheduled with perhaps a luncheon at the Literary Club. On Wednesday afternoon a special train will leave from the Oregon Short Line depot at 12:30 p. m. over the Bingham and Garfield Railroad. Lunch will be served on the train. This trip in addition to magnificent views of Great Salt Lake and Salt Lake Valley will provide an opportunity for Institute members to inspect a typical mining canyon, surface workings of a big mine with mills and smelters. On Wednesday evening there will be a meeting of the Section Delegates and Officers of the Institute and which will be open to all interested. It is hoped Prof. Karapetoff will render a piano recital, a feature which will particularly appeal to those members who have heard his recitals at previous conventions.

Thursday, June 23

Thursday morning, the technical session will be under the auspices of the Transmission and Distribution Committee. The Board of Directors will meet at luncheon, Thursday noon, and follow the luncheon with a short business meeting. Thursday afternoon is assigned to an automobile trip to the Utah Power and Light Company's Terminal Station, the terminus of three 130,000-volt transmission lines, and said to be the largest outdoor substation in the world. Arrangements will also be made for those who wish to devote the time to golf or tennis. For the after-dinner entertainment Dr. Broaddus will deliver an illustrated lecture on the wonderful canyons of Utah.

Friday, June 24

Friday morning, June 24, is assigned for the presentation of various miscellaneous technical papers. On Friday afternoon the finals of the Golf and Tennis Tournaments will be held. Bathing at Saltair Beach is scheduled from 5:00 p. m. to 7:00 p. m., followed either by a dinner in the Ship Cafe or an old fashioned basket picnic with dancing for those who wish it.

Saturday, June 25

On Saturday various *After Convention Trips* have been planned to local points of engineering interest, such as electric railways, power stations, pumping plants, smelters, mills, etc. Trips can also be made to Mountain Parks, Canyons, Brighton, Park City, and Bird Island or to the Shoshone Falls, Bryce Canyon, Zion Canyon, the Grand Canyon and Yellowstone Park.

TENTATIVE PROGRAM OF TECHNICAL SESSIONS

Tuesday, June 21

10:00 A. M.

President's Address—by Arthur W. Berresford.

Technical Committee Reports.

Hydroelectric Developments at Niagara Falls—by J. L. Harper.

Modern Developments in Waterwheels—by W. M. White.

Wednesday, June 22

9:30 A. M.

Economic and Engineering Problems of 220-Kv. Transmission—by L. E. Imlay.

Voltage and Power Factor Control of 66,000-Volt Transmission Lines Connecting Two Generating Stations.—by R. Bailey.

Symposium on Long-Distance Transmission Systems—by F. G. Baum, W. W. Lewis, and L. L. Elden.

Modern Production of Suspension Insulators—by E. H. Fritz and G. I. Gilchrest.

Thursday, June 23

9:30 A. M.

Voltage and Current Harmonics Caused by Corona—by F. W. Peek, Jr.

A Solution of the Porcelain Insulator Problem—by E. E. F. Creighton and F. L. Hunt.

Transformers for Interconnecting High-Voltage Systems or for Feeding Synchronous Condensers from a Tertiary Winding—by J. F. Peters and M. E. Skinner.

Electric Strength of Air under Continuous Potentials and as Influenced by Temperature—by J. B. Whitehead and F. W. Lee.

Friday, June 24

9:30 A. M.

Synchronous Motors for Ship Propulsion—by E. S. Henningsen.

Magnetic Properties of Compressed Powdered Iron, by Buckner Speed and G. W. Elmer.

Heat Losses in Conductors in A-C. Machines—by W. V. Lyon.

Three of the papers listed are published in this issue of the Journal, the balance will appear in the June and later issues.

Sports

In addition to the regular time allotted to sports during the convention, it will be possible for members desiring to devote more attention to this feature to arrange for additional tennis or golf. The gymnasium of the Latter Day Saints immediately adjacent to the hotel will probably be available for the free use of members and will afford special bathing and exercise at any time of day.

Hotel Reservations

All members expecting to attend the convention should if possible, make their hotel reservations immediately.

Convention Headquarters—Hotel Utah, with State Capital in Background

Transportation

It is extremely important that members consult their local railroad agents and decide on the exact and most advantageous route to and from Salt Lake City for their purpose, and make their reservations as early as possible. Summer Excursion Rates take effect June 1st offering round trip fares, considerably below those now prevailing. These tickets permit stop-overs en route and are good until about October 31st.

Arrangements to visit Yellowstone Park, the greatest scenic drawing card in the western United States, can be made either en route to or en route from the convention. The actual round trip fare via Yellowstone will not exceed that to Salt Lake City and return, direct, the only additional expense being for transportation and accommodations in the park. All expenses for the 4½ day trip amounting to \$45.00 via auto and camp route and \$54.00 via auto and hotel route.

As a very large number of eastern members will of necessity pass through Chicago, it is pointed out that the last train leaving Chicago in time to reach Salt Lake City for the first Convention

session, Tuesday morning, June 21st, is train No. 19 over the Chicago and North Western R. R. and Union Pacific R. R. This train leaves Chicago 10:30 A. M., Sunday, June 19th, arriving in Salt Lake 8:20 A. M. Tuesday June 21st. The round trip fare, (summer excursion rates, all roads) from Chicago to Salt Lake City will be $77.76 Persons wishing to go over this route on the train mentioned above should communicate with E. E. Bogardus, City Agents, Chicago & Northwestern R. R., 148 S. Clark St., Chicago, Ill., and obtain their Pullman reservation; additional cars will be added to the train to meet the demand.

Those wishing to return via Kansas City or St. Louis can make the trip via the Denver & Rio Grande R. R. and the Missouri Pacific passing through the magnificent Royal Gorge.

It is assumed that some members will wish to extend their trip to the Pacific Coast and in that event should purchase Pacific Coast Summer Excursion tickets at their initial point with stop over at Salt Lake City; similarly members from the Pacific Coast may obtain summer excursion rates to points in the East with stop over at Salt Lake City.

Temple Block, Salt Lake City

A. I. E. E. DIRECTORS MEETING

APRIL 16, 1921

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at the Colfax Power Station of the Duquesne Light Company, Colfax, Pa., on Saturday, April 16, 1921, at 11:00 a. m.

There were present: President A. W. Berresford, Milwaukee; Vice-Presidents L. T. Robinson, Schenectady, E. H. Martindale, Cleveland; Managers Wm. A. Del Mar, New York, Wilfred Sykes, Chicago, F. D. Newbury, Pittsburgh, H. B. Smith, Worcester, James F. Lincoln, Cleveland; Secretary F. L. Hutchinson, New York.

Reports were presented of meetings of the Board of Examiners held April 1 and 14, 1921; and the actions taken on applications at those meetings were approved.

The Directors ratified the action of the Executive Committee, under date of April 8, in approving applications for admission and transfer, as follows: 200 Students were ordered enrolled; 425 applicants were elected to the grade of Associate; 12 applicants were elected to the grade of Member; 1 applicant was elected to the grade of Fellow; 21 applicants were transferred to the grade of Member; 5 applicants were transferred to the grade of Fellow.

The Meetings and Papers Committee reported, outlining plans for the Institute meeting of May 20 and the Annual and Pacific Coast Convention, June 21-24; also recommending that approval be given to a request of the Marine Committee for a joint meeting to be held with the Society of Naval Architects and Marine Engineers, on Thursday afternoon, November 17, 1921, in New York, during the annual meeting of that society. The report was accepted and the recommendations embodied therein approved.

A petition for the formation of a Connecticut Section, which had been approved by the Chairman of the Sections Committee, was presented and the desired authority granted.

Authority was granted for the organization of a Student Branch at the University of Southern California, Los Angeles.

A communication from the American Engineering Standards Committee was presented, inviting the Institute to become Joint Sponsor with a number of other societies for the unification of specifications for insulated wires and cables for other than telephone and telegraph use. The invitation was accepted and the President was authorized to appoint two delegates to the proposed sectional committee.

An invitation from the American Engineering Standards Committee to send one representative, and any other members of the Institute who may be interested, to conferences regarding the formulation of national symbols for electrical equipment of buildings, was accepted; this request being the outcome of a number of previous conferences between representatives of the National Association of Electrical Contractors and Dealers and the American Institute of Architects, which bodies had formulated a code of symbols in 1911.

In acceptance of an invitation from the University of Minnesota to the Institute to be represented at the inauguration of Lotus Delta Coffman as President of the University, on May 13, 1921, Professor F. W. Springer, of the University of Minnesota, was designated to represent the Institute on that occasion.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the Journal under suitable headings.

AMERICAN ENGINEERING COUNCIL

MEETING IN PHILADELPHIA, APRIL 16

Herbert Hoover Resigns as President

Herbert Hoover has resigned as president of American Engineering Council of the Federated American Engineering Societies. Mr. Hoover's resignation was submitted and accepted as the closing action of the sessions of the council held April 16 at the Engineers Club of Philadelphia. Mr. Hoover gave as his reasons the fact that American Engineering Council by its constitution was necessarily engaged in furthering national activities which involve legislation; and that he as a member of the executive branch of the government could not consistently direct such activity as an officer of American Engineering Council.

The council, in a resolution of regret at Mr. Hoover's retirement, voted its appreciation of Mr. Hoover's leadership during the organization period of the council and his initiation of policies and effort.

The meeting of the council was one of the most important yet held and progress was noted in every direction. The sessions were opened by Calvert Townley as presiding officer. Later Mr. Hoover took the chair and presided over the greater part of the deliberations. Members attending were:

Herbert Hoover, president; Calvert Townley, vice president, representing A. I. E. E.; J. Parke Channing, vice president, representingA. I. M. M. E.; E. Ludlow, president A. I. M. M. E.; F. J. Miller, past president A. S. M. E.; M. L. Cooke, Taylor Society; Wm. McClellan, A. I. E. E.; A. S. Dwight, A. I. M. M. E.; A. M. Greene, A. S. M. E.; Dean of the School of Engineering, Troy Polytechnic Institute; S. H. McCrory, A. S. Agricultural Engineers; W. W. Varney, Baltimore Engineers Club; J. F. Oberlin, Cleveland Engineering Society; O. H. Koch, Technical Club of Dallas; D. S. Kimball, vice president, Dean of School of Engineering of Cornell, A. S. M. E.; Gardner S. Williams, Engineering Society of Grand Rapids; C. F. Scott, A. I. E. E., School of Engineering, Yale University; W. B. Powell, Buffalo Engineering Society; W. E. Rolfe, vice president, Associated Engineering Societies, St. Louis; L. B. Stillwell, A. I. E. E.; L. P. Alford, A. S. M. E.; H. W. Buck, past president A. I. E. E.; E. S. Carman, A. S. M. E., Cleveland; Philip N. Moore, A. I. M. M. E., Washington.

Elimination of Waste in Industry

One of the most important matters before the council was the report of the Committee on Elimination of Waste in Industry, of which J. Parke Channing is chairman and L. W. Wallace, executive secretary of the council, vice chairman. The committee has been conducting an assay of waste in principal industries for more than three months under the direction of Mr. Wallace. The work has been conducted from temporary headquarters in New York. The first reports of the assay will be ready in June. These reports are being put into final form at the permanent offices of the council in Washington, 719 Fifteenth Street.

E. E. Hunt, who has been on Mr. Hoover's staff, and who has been indentified with the Elimination of Waste in Industry Committee since its formation, has been retained to direct the work of that committee until its completion. He will be largely responsible for collating and editing the report. This work will require two or three months.

Employment Service

The report of the Executive Secretary Wallace gave the results of a special study of the Employment Service made by Mark M. Jones. Plans for broadening the scope of the service were recommended and adopted.

Patent Legislation

In submitting the report of the Patents Committee, headed by Edwin J. Prindle, Mr. Wallace noted the favorable attitude of members of Congress toward patent legislation sponsored by the council. Every effort will be made to bring about necessary Patent Office reforms at the present session of Congress.

Licensing of Engineers

Dealing with the licensing and registration of engineers, Mr. Wallace's report said that this had been a very active feature of the council's legislative program. "A number of states have bills before their legislatures on licensing of engineers," Mr. Wallace stated. "We have had representatives attend hearings on such bills from several states. We have emphasized that the position of the council is that we do not believe that such legislation is necessary, but where such is to become a fact we are interested in seeing that the legislation passed is of such character as to be beneficial both to the public and the engineering profession."

Other Activities

Other matters discussed by the secretary were publicity, in which splendid progress was recorded, and which is now in charge of James T. Grady, Director of the Department of Public Information, Columbia University; petitions of the council for the appointment of an engineer as Assistant Secretary of War, in which favorable action was not obtained, and for the appointment of an engineer to the Interstate Commerce Commission, which is still under consideration; a request from the engineers in the public health service for cooperation in legislation that will give them professional standing, favorable action being recommended by the secretary; and closer relations with the government departments both in giving appropriate counsel and in obtaining information which in the form of a bulletin service is being sent out in increasing volume to engineers in member societies.

Public Affairs

The report of the Public Affairs Committee headed by J. Parke Channing was adopted. This report recommended continuance of the public works campaign, to promote which the organization of the National Public Works organization will be continued. The Committee on New York State Government Reorganization reported striking progress. An elaborate report has been submitted to Governor Miller and the Judiciary Committees of both houses of the legislature presenting the engineering point of view as to the making over of the state government. This report has been widely noticed in the press and is having substantial influence on the question of remoulding the state administrative systems.

The executive secretary of the council has been appointed on the Advisory Board to the Board of Surveys and Maps to succeed A. D. Flinn, who represented old Engineering Council. Mr. Wallace also recorded requests for support from the American Engineering Standards Committee in securing legislation to obtain: Official cooperation by the government departments; payment by the government of its own quota of expenses; official recognition of approved specifications in government purchases; government publications of translations of approved specifications for the promotion of foreign trade.

New Member Societies

Three new member societies have joined the Federation since the last meeting. They are the Boston Society of Civil Engineers and the Engineering Societies of Milwaukee and Duluth.

Other important additions to the Federation's swelling membership and influence are expected to be announced before July 1.

Next Meeting in St. Louis

The next meeting of the Council will be held in St. Louis, June 3. This meeting will probably be the most important yet held by the society. It will synchronize with the report on the waste assay and will mark another progressive stage in the work of organization. For the intervening period Mr. Wallace and his associates mapped out a vigorous campaign of constructive effort.

DELEGATION OF AMERICAN ENGINEERS TO PRESENT JOHN FRITZ MEDAL TO SIR ROBERT HADFIELD

To express the obligation which the world owes to the engineers of Great Britain for the part they played in winning the war, the engineers of America will send a mission to London this summer. The mission, consisting of nationally known engineers and representing the National societies of Civil. Mining, Mechanical and Electrical engineers, will present the John Fritz Medal to Sir Robert Hadfield at the opening meeting of the British Institution of Civil Engineers on June 29.

The inability of Sir Robert to come to the United States to receive the medal moved the trustees of the Board of Award to make the ceremony of presentation in England the occasion for an international expression of appreciation.

The deputation to England will consist of a representative of each of the four Societies represented on the John Fritz Medal Board of award as follows:

Charles T. Main of Boston, the American Society of Civil Engineers; Colonel Arthur S. Dwight of New York, the American Institute of Mining and Metallurgical Engineers; Ambrose Swasey of Cleveland, the John Fritz Medal Board of Award and the American Society of Mechanical Engineers: Dr. F. B. Jewett of New York, the American Institute of Electrical Engineers. Dr. Ira N. Hollis, President of the Worcester Polytechnic Institute and past president of the American Society of Mechanical Engineers, will accompany the deputation and bear the message from the American engineers.

The John Fritz Medal is presented for achievement in applied science as a memorial to the engineer whose name it bears. The medal was awarded to Sir Robert this year because of his invention of manganese steel. It was originated by the professional associates and friends of John Fritz of Bethlehem, Pa., on Aug. 21, 1920, his eightieth birthday, to perpetuate the memory of his achievements in industrial progress.

INSTITUTE PRIZES

As announced in the April issue of the JOURNAL, the Board of Directors of the Institute has established two Institute prizes to be awarded to authors of worthy papers, and the Committee on Coordination of Institute Activities was charged with the duty of formulating the procedure to be followed in making the award. This Committee held a meeting on March 11th and prepared its recommendations, which were submitted to, and approved by, the Board of Directors at a meeting held in Pittsburgh, April 16th. The following extracts from the report of the Committee embody the essential features of the procedure to be followed:

THE FIRST PAPER PRIZE

(1) This prize, established by the Board of Directors of the Institute, January 14, 1921, shall consist of $100 cash, and a suitable certificate, to be awarded each year to the author of the paper which is designated by a duly authorized committee of award as the most worthy original paper, presented during the year at a meeting of any Section of the Institute, by a member of the Institute who has never before presented a paper before the Institute or any of its Sections.

(2) To be considered for competition, the author, or an officer of the Section at which the author's paper was presented, shall submit the paper to the committee of award, by means of a written communication to the Secretary of the Institute, prior to January 15 of the year following the calendar year in which the paper was presented.

(3) Papers by joint authors are eligible for this competition, provided both authors meet the qualifications, in which case the prize shall be divided equally between the authors.

(4) The award shall be made by a committee consisting of the Chairman of the Meetings and Papers Committee as chairman, and the chairmen of the technical committees of the Institute, prior to June 1.

(5) The prize shall be presented at the Annual Convention of the Institute.

(6) The paper shall be published in the monthly JOURNAL or annual TRANSACTIONS of the Institute, or both.

(7) Manuscripts shall be submitted in duplicate and shall be typewritten on one side of paper of approximately 8½ by 11 inches. The letter entering the paper in the competition need not be accompanied by duplicate copies of the paper, provided suitable manuscript copies in duplicate have been submitted previously.

THE TRANSMISSION PRIZE

(1) This prize, established by the Board of Directors January 14, 1921, shall consist of $100, and a suitable certificate, to be awarded each year to the author of the paper which is designated by a duly authorized committee of award as the most worthy paper dealing with the art of transmitting electrical energy over considerable distances, presented during the year by a member of the Institute, at a meeting of the Institute or of any of its Sections.

(2) To be considered for competition, the author shall submit the paper to the committee of award, by means of a written communication to the Secretary of the Institute, prior to January 15 of the year following the calendar year in which the paper was presented.

Paragraphs three to seven, as printed above under the heading "The First Paper Prize", also apply to this award.

As stated in the April issue of the JOURNAL, papers presented before the Institute during the calendar year 1921 will be eligible for these competitions.

AMERICAN ENGINEERING STANDARDS COMMITTEE

ANNUAL REPORT ISSUED

Although the American Engineering Standards Committee has been actively at work for only slightly more than one year and much of the time and effort of the Committee has necessarily been spent in laying a basis for work the fruition of which will require at least two or three years, yet considerable progress has already been made in the unification of the more important standards and in overcoming the confusion that was being produced by numerous organizations (more than 100) that hitherto published engineering standards without systematic cooperation among themselves.

Prior to December 31, 1920, there had been approved by the Committee "Tentative American Standard Specifications and Tests for Portland Cement", "Tentative American Standard Specifications for Fire Tests of Materials and Construction," and "American Standard Pipe Threads." Moreover there had been submitted for approval by the Committee the "National Electrical Code" as an American Standard, and "Standard Test for Toughness of Rock," "Standard Method of Distillation of Bituminous Materials for Road Treatment," and "Standard Method of Sampling Coal," as Tentative American Standards, with the "Safety Code for Head and Eye Protection" submitted for approval as "Recommended American Practise."

The Committee itself is composed of 47 members representing 17 bodies or groups of bodies, including six national engineering societies, five Governmental departments and 13 national industrial associations. Its function is merely to see that each body or group concerned in a standard shall have opportunity to participate in its formulation which is in the hands of a working committee, technically called a "sectional committee." Each sectional committee is organized by, and under the leadership of, one or more of the principal bodies interested, such bodies being known as "sponsors." Sponsorships have been arranged for the following projects which were under way by the beginning of this year:

Electrical Projects. "Rating of Electrical Machinery" and "Terminal Markings for Electrical Apparatus".

Mechanical Projects. "Ball Bearings," "Plain Limit Gages," "Gears", "Machine Tools," "Nut and Bolt Heads," "Pipe Flanges and Fittings", "Screw Threads," "Shafting".

General Projects. "Passenger and Freight Elevators," "Color Scheme for Pipe Line," "Steel Shapes," "Zinc Ores and Zinc."

Safety Codes. "Aviation Safety Code," "Construction Work," "Electrical Fire Code," "Electrical Safety Code," "Floor Openings, Railings Toe Boards," "Foundries", "Gas Safety Code," "Grinding Wheels," "Head & Eye Protection," "Ladder Code" "Lighting Code," "Lightning Protection," "Logging Operations and Sawmill Machinery," "Machine Tools," "Mechanical Transmission of Power," "Paper and Pulp Mills," "Electrical Power Control," "Power Presses," "Mechanical Refrigeration," "Industrial Sanitation," "Stairways, Fire Escapes and Other Exits," "Textiles," "Ventilation," and "Woodworking Machinery."

As will be seen from the above lists, an important part of the Committee's work relates to safety codes. On December 8, 1920 at a conference at which more than 100 organizations were represented it was unanimously voted that a comprehensive program of safety codes should be undertaken, to be carried out under the auspices of the American Engineering Standards Committee to insure proper coordination and elimination of overlap, etc. Active work is now in progress on 24 such codes with hearty cooperation among the state commissions, associations of insurance companies, national engineering societies, manufacturers' and industrial associations, labor and civic organizations, and technical bureaus of the Federal Government. As is true of all work under the auspices of the American Engineering Standards Committee, such of the bodies as are interested in the particular code in question are represented in the committees responsible for the formulation of each code.

Copies of the Report may be obtained by addressing a request to the American Engineering Standards Committee, 29 West 39th Street, New York.

AUTOMOBILE HEADLIGHTING SPECIFICATIONS

The Illuminating Engineering Society has submitted its "Automobile Headlighting Specifications" to the American Engineering Standards Committee for approval. The specifications are submitted in accordance with the special provision in the procedure of the Committee, under which important standards in existence prior to 1920 may be approved without going through the regular process followed in new work.

The specifications have been adopted in their essential details by the States of Wisconsin, Connecticut and Maryland, and by the Province of Ontario, and have been endorsed by the Standards Committee of the Society of Automotive Engineers by the International Traffic Officers' Association, and by the conference committee on Uniform Vehicle Laws representing some 30 different organizations under the auspices of the National Safety Council.

The Headlighting Specifications of the Illuminating Engineering Society may be found in the *Transactions* of the Society, Vol. XV, No. 4, June 10, 1920. Copies may also be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York. Price 10 cents.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute Records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Leo Arany, Room 201 Parkway Bldg., Broad & Cherry Street, Philadelphia, Pa.

2.—De Los De Tar, 411 East 15th Street, Kansas City, Mo.

3.—George W. Huey, R. F. D. No. 5, Wilkinsburg, Pa.

4.—Major, J. E. H. Stevenot, c/o Bureau of Insular Affairs, War Dept., Washington, D. C.

5.—Murel A. D. Summer, c/o Pittsburgh Transformer Co., Pittsburgh, Pa.

PERSONAL MENTION

E. F. W. Alexanderson, chief engineer, Radio Corporation of America, is in Europe on a business trip.

Clarence J. Berry of Paris, France, has gone into business for himself, specializing in illuminating engineering work in France.

Lloyd E. Oneal has left Dwight P. Robertson & Co., Inc., New York, and is now located with Chas. Cory & Son, Inc., New York.

F. J. Robbins, formerly of Tacoma, Washington, has been since April 1st with Grays Harbor Railway, Light and Power Company, Aberdeen, Washington.

Walter D. Royer has left his position as branch manager in Pittsburgh of the Black & Decker Mfg. Co. of Baltimore, to become sales engineer for McGraw Company, Sioux City, Iowa.

P. G. Agnew, secretary of the American Engineering Standards Committee, sailed for England in April to attend a conference of secretaries of national standardizing bodies held in London.

Albert Kingsbury, who was formerly located in the Oliver Building, Pittsburgh, is now conducting his engineering business under the name of Kingsbury Machine Works, located at Frankford, Philadelphia, Pa.

George S. Davis, in charge of the radio service of the United Fruit Co., has been elected a director of the Radio Corporation of America. Mr. Davis is also president of the Wireless Specialty Apparatus Co., of Boston, Mass.

J. J. Gaffey, assistant engineering manager of the Harry M. Hope Engineering Company, Boston, announces that the company has established offices in the Dominion Express Building, Montreal, to handle its Canadian business.

Harry B. Joyce, formerly a major in the Construction Division of the army, has resigned as a member of the firm of Johnson and Benham, Inc., consulting engineers, to assume charge of the engineering work of the Centrifugal Fan Company Newark, N. J.

Robert J. Mailhouse and Joseph N. Golding have severed their connections with the Interborough Rapid Transit Company of New York City and have opened an office in the Chamber of Commerce Building in New Haven, Conn., where they will practise engineering under the name of Mailhouse & Golding, Incorporated.

Howard M. Raymond has been appointed as acting president of the Armour Institute of Technology to fill temporarily the vancancy caused by the death of Dr. F. W. Gunsaulus. Acting president Raymond has been connected with the Armour Institute for the past twenty-six years, and has served as dean of engineering since 1903.

Frederick G. Simpson announces the establishment of his offices in the L. C. Smith Building, Seattle, Washington. Mr. Simpson is an experienced electrical engineer, formerly connected with Kilbourne & Clark Mfg. Co., Seattle, as chief engineer and general manager. During the war he was officer in charge of radio material activities, United States Navy, on the North Atlantic Coast.

F. B. JEWETT, chief engineer of the Western Electric Company, has been elected a vice-president and director of his company. He will continue his present duties in charge of the technical forces. Dr. Jewett is well-known for his contributions in the telephone field; the perfection of wireless telephony is one of the undertakings completed under his direction. During the war he was a Lieutenant-Colonel in the Signal Corps, and was decorated with the Distinguished Service Medal. As an advisory member of the Special Submarine Board of the Navy he contributed much toward the perfection of devices for detecting hostile submarines. Dr. Jewett is a Fellow and a former vice-president of the INSTITUTE.

JAMES R. BIBBINS has resigned as supervising engineer of the Arnold Company, Chicago, to accept an appointment as manager of the Department of Transportation and Communication of the United States Chamber of Commerce, Washington, D. C. This new Department will have a wide range of activities, covering shipping, ocean and inland; steam and electric railroad transportation, air transportation, cables and telegraphs, postal facilities, and highways. Mr. Bibbins brings to it a wide experience in the transportation field, including over ten years' association with Bion J. Arnold, consulting engineer, and president of the Arnold Company, in consulting work dealing with the transportation problems of a number of the large cities of the United States and Canada. He is a Fellow of the INSTITUTE, and has been serving as chairman of the Chicago Section.

OBITUARY

LESTER GRAY FRENCH, for thirteen years editor and manager of "Mechanical Engineering," the journal of the American Society of Mechanical Engineers, and assistant secretary of the society, died on April 18th, 1921, at the French Hospital, New York City, from septic poisoning following an operation. Mr. French was born in Keene, N. H., in April 1869, and was graduated from the Massachusetts Institute of Technology in 1891. After serving for a year as draftsman with the Cranston Printing Press Company he took up the teaching of mechanical engineering until 1895, when he entered the employment of the Builders Iron Foundry as assistant to the superintendent. In 1897 he became editor-in-chief of "Machinery," and continued in this position for about ten years, resigning to take up the publication of technical books, among them being one of the earliest treatises on the steam turbine, of which he was the author. He was made editor of the publications of the American Society of Mechanical Engineers in 1908. Mr. French was a member of the American Society of Mechanical Engineers, and also of the Engineers Club of New York. His home was in White Plains, N. Y.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (MARCH 1-31, 1921)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or text of the book.

All books listed may be consulted in the Engineering Societies Library.

ARCHIMEDES.

By Sir Thomas Heath. Lond., Society for Promoting Christian Knowledge; N. Y., The Macmillan Co., 1920. (Pioneers of Progress), 58 pp., front., 7 x 5 in., cloth $.80.

Sir Thomas Heath has written an interesting brief account, ample for the general reader, of the contributions of Archimedes to mathematics and mechanics, and the significance of his work.

BELTS FOR POWER TRANSMISSION.

By W. G. Dunkley. Lond., and N. Y., Sir Isaac Pitman & Sons, Ltd. (Pitman's technical primer series.) 104 pp., diagrams, 7 x 4 in., boards, $1.00.

Contents: Belt materials and types of belts.—Power transmitted by belts.—The "Lenix" system of belt driving.—Length of belts.—Steel belts.

This is a small volume, for students and designers, presenting and discussing the factors and considerations involved in belt driving. Tables of use to designers are included.

THE COMPLETE AIRMAN.

By G. C. Bailey. N. Y., E. P. Dutton and Co. 269 pp., plates, diagrams, 9 x 6 in., cloth. $6.00.

This book discusses aviation in a more or less elementary fashion, for those generally interested in its technical aspects, pilots, mechanics, and managers of commercial enterprises connected with aviation. The theory of flight, the care and construction of machines, practical flying, and auxiliary equipment are considered in a non-technical manner.

COMPRESSED AIR.

By Theodore Simons. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 173 pp., illus., tables, 9 x 6 in., cloth. $2.00.

This treatise is intended to give the student such an insight into the natural laws and physical principles underlying the production, transmission and use of compressed air, as will enable him to comprehend the operation of the various appliances used for this purpose and to judge of their merit. The present edition has been carefully revised and partly rewritten.

COPPER REFINING.

By Lawrence Addicks. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 211 pp., illus., tables, 9 x 6 in., cloth. $3.00.

Contents: Metal losses.—Metals in process.—Tank resistance.—Current Density.—Current efficiency.—Impurities.—By-products.—Furnace refining.—The requirements of re-

fined copper.—Copper from secondary material.—The power problem.—Elements of design.—Application to other fields.
Electrolytic copper refining was for so many years conducted under conditions of strict commercial secrecy that but little has been published regarding the principles of operation, as distinct from descriptions of individual plants.
This little book, comprising a series of articles, each dealing with one of the problems of refining, which originally appeared in *Chemical and Metallurgical Engineering*, is almost entirely a record of the author's personal experience.

Davison's Silk Trade.
Twenty-sixth annual edition, 1921. Pocket edition. N. Y., Davison Publishing Co. 776 pp., 8 x 5 in., cloth. $4.00.

The directory of silk mills is arranged both geographically and by products, dyers and finishers geographically, the dealers by commodities. An index of mills is included. Full information as to the size of mills, their products, officers, etc., is included.

Davison's Textile "Blue Book," United States and Canada.
Thirty-third annual edition, July, 1920 to July, 1921. Office edition. N. Y., Davison Publishing Co. 1748 pp., maps, 9 x 7 in., cloth, $7.50.

This directory covers the entire textile industry. The mills of the country are listed geographically under their products, and their sizes, officers and products noted. Commission merchants, dealers in raw and semi-finished materials, rags, waste, etc., are also included, and also a directory of dealers in textile mill supplies.

The Dynamics of the Airplane.
By Kenneth P. Williams. N. Y., John Wiley & Sons Inc.; Lond., Chapman & Hall, Ltd., 1921. (Mathematical monographs, 21.) 138 pp., diagrams, 9 x 6 in., cloth, $2.50.

Contents: The plane and cambered surface.—Straight horizontal flight.—Descent and ascent.—Circular flight.—The propeller. Performance.—Stability and controllability.
This book, intended for students of mathematics and physics who are attracted by the dynamical aspect of aviation, grew out of a course of lectures on aerodynamics given by Professor Marchis, at the University of Paris in 1919. The treatment is elementary for the most part.

E. I. Du Pont de Nemours and Company; a history 1802-1902
By B. G. du Pont. Bost. and N. Y., Houghton Miflllin Co. 1920. 196 pp., port., plates, facsims., 8 x 6 in., cloth, $3.00.

A brief general account of the growth and achievements of this company from its foundation by E. T. du Pont de Nemours, to its purchase and reorganization by T. Coleman du Pont and his associates.

Electric Welding.
By Ethan Viall. First edition. N. Y., and Lond., McGraw-Hill Book Co., Inc., 1921. 417 pp., illus., 9 x 6 in., cloth, $4.00.

Contents: Electric welding—historical.—Arc welding equipment.—Different makes of arc welding sets.—Training arc welders.—Carbon-electrode arc welding and cutting.—Arc welding procedure.—Arc welding terms and symbols.—Examples of arc-welding jobs.—Physical properties of arc-fused steel. Metallography of arc-fused steel.—Automatic arc welding.—Butt-welding machines and work.—Spot-welding machines and work.—Welding boiler tubes by the electric resistance process.—Electric welding of high-speed steel and stellite in tool manufacture.—Electric seam welding.—Making proper rates for electric welding, and the strength of welds.
This volume is a compilation of the available literature on electric welding, selected and arranged by an experienced editor. It forms a convenient source of information on present methods, apparatus and applications.

Electrical Machinery
By Ottomar H. Henschel. Chicago, Power Plant Engineering, (cop. 1920). 312 pp., illus., 8 x 5 in., cloth, $2.00.

This volume is an elementary statement of the generally accepted theories of the principles of electric machinery, presented with the aid of only elementary mathematics. Direct and alternating-current generators and motors, transformers, voltage regulators and synchronous converters are considered. The book is based upon a series of articles, entitled "A study of dynamo electric machinery," which appeared in *Power Plant Engineering*.

Elementary Machine Shop Practise.
By James A. Pratt. N. Y., D. Van Nostrand Co., 1921. 320 pp., illus., 8 x 5 in., cloth, $2.50.

This manual describes the fundamentals of the trade, the processes relating to the bench, lathe, drill press, shaper, slotter, grinder, miller and planer. The treatment is clear, detailed and non-mathematical. Suited for use by apprentices, trade school students and young workmen.

Elements of Fuel Oil and Steam Engineering.
By Robert Sibley and C. H. Delany. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 466 pp., illus., tables, 9 x 6 in., cloth, $5.00.

The theme of this book is a study of fuel-oil power-plant operation and the use of evaporative tests to increase their efficiency. It includes an exposition of the elementary laws of steam engineering, the use of oil for fuel in the modern power plant, and the testing of oil-fired boilers. This edition has been rewritten, and much new material added.

Employee Training.
By John Van Liew Morris. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 311 pp., 8 x 6 in., cloth. $3.00.

This work presents the results of an inquiry into the programs and organization machinery being utilized by various manufacturing concerns to train their own workers, both by apprenticeship courses and by vocational training. It shows industry's own solution of its training problems and should be suggestive to manufacturers as a collection of tried methods.

Hendrick's Commercial Register of the United States.
29th annual edition (1921).

N. Y., S. E. Hendricks Co., Inc., 2572 pp., 10 x 8 in., cloth, $12.50.

This well-known classified directory of manufacturers and dealers in supplies used by engineering firms has been carefully revised, new firms have been added, and those no longer extant have been eliminated. As in previous issues, the directory includes a classified list of dealers, an alphabetical list, an index of trade names, and an index of commodities.

Installing Management in Woodworking Plants.
By Carle M. Bigelow. N. Y., The Engineering Magazine Co., 1920. 323 pp., illus., 9 x 6 in., cloth, $5.00. (Gift of Industrial Management.)

Contents: Traditional peculiarities of woodworking making scientific management essential.—Organization and its installation.—Product.—Lumber.—Purchasing and storing.—Planning department.—Layout and routing of the plant.—Shop practise and standardization.—The cutting of lumber—Labor control.—Tool and fixture control.—Repair control.—Waste Control.—Power plant.—Cost accounting.—Results to be expected by application of methods outlined.
The author's purpose has been two-fold; first, to express in a general way his ideas as to the application of the principles of scientific management to an industry, and second, to outline in detail their application to the specific problems of the woodworking industry.

Kinematics and Kinetics of Machinery; a Text-Book for Colleges and Technical Schools.
By John A. Dent and Arthur C. Harper. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 383 pp., illus., tables, 9 x 6 in., cloth, $3.50.

Contents: Machine Motions, Pairs, Links, Chains, Mechanisms.—Motion of Rigid Bodies.—Velocities of Mechanisms.—Accelerations in Mechanisms.—Inertia Forces of Machine Parts.—Balancing of Engines.—Governors.—The Mechanics of the Gyroscope.—Critical Speeds and Vibrations.—Toothed Wheels.—Cams.—Wrapping Connectors.—Irregular Gears.—Propositions on Velocity Polyglons.—Locus of the Center of Acceleration.—Solution of Linear Differential Equations.—Investigation of Forces in Gasoline Engine.
This treatise gives systematic methods, mainly graphical, of determining velocities, accelerations and inertia forces which can be applied to practically all mechanisms. The text is based upon notes prepared by professors G. A. Goodenough and F. B. Seeley, and used for instruction at the University of Illinois, which have been revised and extended by the authors.

THE MANUFACTURE OF PULP AND PAPER. Vol. 1. Arithmetic, Elementary applied mathematics. How to read drawings. Elements of Physics.

By J. J. Clark. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 132 pp., illus., 9 x 6 in., cloth, $5.00.

This book is the first of a series of five volumes prepared under the auspices of the Canadian Pulp and Paper Association and the Technical Association of the Pulp and Paper Industry, which is intended to form a suitable course of study in the fundamentals of mathematics and science and the manufacturing operations involved in modern pulp and paper practise. The treatment is simple, as the books are intended for self-instruction, as well as for class room use.

MARINE ENGINEERING.

By A. E. Tompkins. Fifth edition, revised. Lond., Macmillan and Co., Ltd., 1921. 888 pp., illus., 9 x 6 in., cloth. $11.25. (Gift of the Macmillan Co., N. Y.)

An extensive one-volume text-book covering a sound course in marine engineering, treating all the subjects usually included in that term. This edition has been extensively revised and many chapters have been rewritten. Much obsolete matter has been omitted and mercantile practise has been considered more fully than before.

MODERN MARINE ENGINEERING. Part 1. The Fire Room.

By Harry G. Cisin. N. Y., D. Van Nostrand Co., 1921. 205 pp., illus., tables, 8 x 5 in., cloth. $3.00.

The purpose of the text-book of which this is a first volume, is to set forth present practise in marine engineering in a form suitable as a college text or for use by practical men preparing for engineers' licenses. This volume discusses marine boiler construction, auxiliaries, corrosion, fuels and combustion. It is based on the course given by the U. S. Navy Steam Engineering School at the Stevens Institute, during the war.

THE NEW PHYSICS.

By Albert C. Crehore. San Francisco, *Journal of Electricity*, 1920. 111 pp., 6 x 5 in., cloth.

This little book presents some results of the author's study of the fundamental conceptions and laws of physics. It gives new expressions for Rydberg's and Planck's constants, which connect them in various ways with the electrical charge and the mass of the hydrogen atom, a reduction of the electrostatic and electromagnetic systems of the units to one common system in terms of length and time, and the author's theory of the atom.

PLANE ALGEBRAIC CURVES.

By Harold Hilton. Oxford, Clarendon Press, 1920. 388 pp., diagrams, 9 x 6 in., cloth, $12.60. (Gift of the American Branch of the Oxford University Press.)

Though the theory of plane algebraic curves still attracts mathematical students, the English reader has not many suitable books at his disposal. Salmon's classic treatise was last published some forty years ago and has long been out of print. Mr. Hilton has therefore thought a new book desirable, if only to bring more recent developments within reach of the student. His book, while based on previous texts, has been largely extracted from mathematical periodicals, supplemented by his own studies, and attempts to be reasonably complete.

PRINCIPLES OF ELECTRICAL DESIGN, D-C. AND A-C. GENERATORS.

By Alfred Still. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 365 pp., diagrams, 9 x 6 in., cloth. $3.50.

This book is intended for students of electrical engineering and for this reason emphasis is laid on fundamentals and principles of general application, while little attention is given to the need of the practical designer for empirical formulas and short cuts. The author's object has been to supply a reference text to accompany a course in practical designing, which would base all arguments on scientific facts and build up designs in a logical manner from known fundamental principles, and thus assist in a thorough understanding of the essentials.

The revision covers many minor alterations and corrections and a few new methods of calculation.

THE PRINCIPLES OF THE PHASE THEORY.

By Douglas A. Clibbens. Lond., Macmillan and Co., Ltd., 1920. 383 pp., diagrams, 9 x 6 in., cloth. $10.00. (Gift of The Macmillan Co., N. Y.)

As the author believes that a thorough study of the condensed system offers the easiest path to a true understanding of the methods of the phase theory, he has given a general title to his book, which in reality is limited to the consideration of condensed systems which include only one liquid phase, and that the only phase of variable composition. The book is written primarily for readers unfamiliar with the subject.

SCREW THREAD PRODUCTION TO CLOSE LIMITS.

By Howard E. Adt. First edition. N. Y., The Stirling Press, 1920. 192 pp., illus., tables, 9 x 6 in., cloth. (Gift of the Geometric Tool Co., New Haven.)

The volume is intended primarily to direct attention to the screw cutting tools and machines manufactured by the Geometric Tool Co. It contains much general information of a practical character on screw thread standards, gaging, methods of threading, cutting speeds, lubricants, and similar subjects of general application, and includes the necessary tables, so that it will be useful to machinists as a reference book.

STUDIES IN FRENCH FORESTRY.

By Theodore S. Woolsey, Jr. With two chapters by W. B. Greeley. N. Y., John Wiley & Sons, Inc., Lond., Chapman & Hall, Ltd., 1920. 550 pp., illus., tables, 9 x 6 in., cloth, $6.00.

Contents: Impressions of French forestry.—The role of forest.—Forest regions and important species.—Forest statistical data.—Natural regeneration.—Artificial reforestration.—Control of erosion in the mountains.—Forestry in the Landes.—Government regulation and working plans.—Features of French national forest administration.—Private forestry in France.—The American forest engineers in France.

This book is a study of the theory and practise of French forest administration and management, based upon extended trips through French forests, and an examination of the standard authorities. It supplements the author's previous volume "French Forests and Forestry," which describes the forests and forestry of Algeria, Tunisia and Corsica.

TECHNICAL METHODS OF ANALYSIS, AS EMPLOYED IN THE LABORATORIES OF ARTHUR D. LITTLE, INC., CAMBRIDGE, MASS.

Edited by Roger Castle Griffin. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. (International chemical series.) 666 pp., illus., tables, 8 x 6 in., cloth, $5.00.

This is an extensive handbook for the analytical chemist, based on the experience of a large commercial laboratory, in which most of the methods given have been used many times. Standard procedures adopted by bodies of chemists have also been included.

The book is intended to include the methods commonly needed in general commercial work, but material on drugs, alkaloids, medicines, rare earths, rocks, glasses and other substances has been excluded. The chief materials discussed are the important organic compounds, metals, fuels, paints, oils, fats, soaps, wood, paper, textiles and foodstuffs. Brief descriptions of the normal properties are frequently given. Bibliography, pp. 627-633.

A TEXT-BOOK OF ELECTRICAL ENGINEERING.

By Adolf Thomalen, translated by G. W. O. Howe. Fifth edition, Lond., Edward Arnold, 1920. 482 pp., diagrams, 9 x 6 in., cloth, $9.00. (Gift of Longmans, Green and Co.)

This book is designed to bridge the gap between elementary text-books and the specialized works on various branches of electrical engineering. It is concerned almost exclusively with principles and does not enter into details of the practical construction of apparatus and machines. It is intended to lay a thorough foundation for the profitable study of books on the design of dynamo machinery.

The present edition has been revised, extended and partly rewritten.

A TEXT-BOOK OF ORGANIC CHEMISTRY.

By A. F. Holleman. Edited by A. J. Walker, assisted by O. E. Mott. Fifth English edition, completely revised. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall Ltd., 1920. 642 pp., illus., 9 x 6 in., cloth, $3.50.

Most of the short text-books of organic chemistry, according to this author, contain a great number of isolated facts and describe so considerable a number of compounds that the beginner is confused. Moreover, the theoretical grounds are often kept in the background. In this book he has endeavored to keep the number of unconnected facts within narrow limits and to give prominence to the underlying theory.

The present edition has been carefully revised and partly rewritten.

A TEXT-BOOK OF PHYSICS.

By W. Watson. Seventh edition, revised by Herbert Moss, Lond., and N. Y., Longmans, Green & Co., 1921. 976 pp., illus., diagrams, 8 x 5 in., cloth, $6.00.

Since the publication of the sixth edition, this text-book has undergone considerable revision, during which those sections dealing with subjects in which important recent work has been done, have been revised and extended.

The book is intended for students of college grade, already familiar with the elements of the subject, who desire a more extended discussion.

TRADE TESTS: THE SCIENTIFIC MEASUREMENT OF TRADE PROFICIENCY.

By J. Crosby Chapman, with the assistance of D. R. Chapman, N. Y., Henry Holt and Co., 1921. 435 pp., illus., 9 x 6 in., cloth, $4.00.

During the war, the War Department undertook extensive researches in the effort to solve the problem of placing its skilled workers. One important result of the experimentation was the trade test, devised to enable a trained examiner, unskilled in any trade, to measure the trade standing of a person claiming skill in any of the trades necessary to the army.

The present volume sets forth some of the results obtained. Samples of oral picture, performance and written trade tests for various trades are shown, with comment on their use. The place of such tests in industry is discussed.

A TREATISE ON AIRSCREWS.

By Whyrill E. Park. N. Y., E. P. Dutton & Co., 1921. (The Directly-Useful Technical Series.) 308 pp., illus., diagrams, charts, tables, 9 x 6 in., cloth, $8.00.

This book considers the problems of airscrew propeller design and construction from the viewpoint of designers, draftsmen and others engaged in the practical design of aircraft. In general, it follows the methods developed by Lang Propeller, Ltd. It is intended to supply directly useful information, accompanied by a proper amount of scientific explanation. The theory presented is one that has proved convenient for drafting-room use.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—March 23, 1921. Subject: "The Panama Canal and its Electrification." Speaker: Mr. D. C. Hooper. Mr. Henton, a visitor, also gave a talk on gold metallurgy, making particular reference to the Black Hill Section in South Dakota. Attendance 16.

Boston.—March 15, 1921, Engineers Club. Paper: "High Lights of Air Travel." Author: Mr. M. Luckiesh, Director of Applied Science, Nela Research Laboratory, Clevel nd, O. The paper dealt with the beauties, wonders and possibilities of airplane flights. Attendance 94.

Cleveland.—March 14, 1921. Cleveland Social Club Rooms. Joint meeting with the Association of Iron and Steel Electrical Engineers. Paper: "Electric Propulsion of Ships." (by Mr. W. E. Thow.) Speaker: Mr. Ralph Kelley, who has worked with the author in this field. Attendance 120.

Denver.—March 19, 1921, Kenmark Hotel. Subject: "Valuation and Rate Making Concerning Utilities." Speakers: Messrs. G. H. Throop and H. A. Belden, Valuation Engineers for the J. G. White Engineering Corporation of New York. Attendance 50.

Fort Wayne.—March 24, 1921, General Electric Club Rooms. Subject: "Modern Transformer Practise." Speaker: Mr. E. A. Wagner. Mr. Wagner discussed the development and construction of several different types of transformers which are built at Fort Wayne, and slides were shown illustrating the details of construction. Attendance 27.

Kansas City.—March 25, 1921, Northeast Power House of Kansas City Light and Power Company. Subject: "Construction of the Northeast Power House." Speaker: Mr. H. C. Blackwell, General Manager, Kansas City Light & Power Company. Mr. R. Frisbie also discussed the Generator and Station Protection as installed at the Northeast Power House. Attendance 56.

Los Angeles.—March 22, 1921, Edison Hall. Subject: "Our Debt to the Pioneers of Science." Speaker: Mr. Samuel G. McMeen. Entertainment, movies and music followed. Attendance 130.

Lynn.—March 19, 1921, City Club, Boston. Tenth Annual Banquet of the Section. After the banquet two films were shown, one of the operation of X-Ray Apparatus and the other on the application of electricity to logging operations and lumber mills. General T. C. Dickson, Commandant of the Watertown Arsenal, gave a very interesting lecture on the labor situation during the war and how it was handled by the Government; followed by Professor Arthur Gordon Webster, of Clark University, who in a humorous way told how to get rich. Other speakers were Professor Elihu Thomson, Richard H. Rice and F. P. Cox. Attendance 390.

April 6, 1921, Classical High School, Lynn. Ladies' Night. Mr. John B. Taylor, of the General Electric Company, Schenectady, gave a very interesting lecture on "Instruments of the Orchestra," explaining why and how sounds are produced on various orchestral instruments and the value to the orchestra as a whole. The lecture was preceded by a concert given by two soloists and a large orchestra, all of whom were employees of the General Electric Company. Attendance 750.

Minnesota.—February 28, 1921, Auditorium, University of Minnesota. Subject: "Radio Telephone." Speaker: Professor C. M. Jansky, Jr. of the University of Minnesota. Prof. Jansky gave a very interesting history of the development of the Radio Telephone and a description of the apparatus used in the early experimental stages and the development of this apparatus to that used today. He demonstrated these various pieces of apparatus and diagrams of circuits on the blackboard. Attendance 120.

Omaha.—March 21, 1921, University Club. Organization meeting. Temporary officers: Chairman, Mr. H. C. Evarts; Secreatry, Mr. L. E. Rudolph. Attendance 10.

Philadelphia.—March 22, 1921, Witherspoon Hall. Subject: "How the Engineer Can Best Capitalize Himself." Speaker: Mr. Richard Spillane. Joint meeting with affiliated societies of the Engineers' Club of Philadelphia and the Engineers' club. Attendance 925.

April 11, 1921, Engineers' Club of Philadelphia. Subject: "Niagara Falls Power and the Reason for its Development." Speaker: Mr. John L. Harper, Vice-President and Chief Engineer of Niagara Falls Power Company. Attendance 83.

Pittsfield.—March 17, 1921, Boys' Club. Subject: "Wireless Telephony." Speaker: Dr. B. F. Jewett, Chief Engineer, Western Electric Company. Attendance 250.

March 31, 1921, Park Club. Subject: "Airplane Flight." Speaker: Dr. Frederick Bedell, Cornell University. Attendance 135.

Providence.—March 15, 1921, Providence Engineering Society Rooms. Joint meeting with Providence Engineering Society. Subject: "Electrification of Steam Railroads." Speaker: Mr. C. C. Whittaker, of the Westinghouse Elec. & Mfg. Co., E. Pittsburgh. The talk was illustrated with lantern slides. Attendance 60.

April 1, 1921, Engineering Society Rooms. Joint meeting with the Telephone Society of Rhode Island. Subject: "The Practical Application of Telephone Repeaters." Speaker: Mr. H. S. Osborne, Transmission Engineer of the A. T. & T. Co. The talk was illustrated with lantern slides. Attendance 50.

Rochester.—March 25, 1921, Subject: "Einstein Theory of Relativity." Speaker: Dr. Arthur S. Gale, Professor of Mathematics of the University of Rochester. The speaker summarized the historical development of the theory of relativity, describing the classic experiment of Michelson undertaken to determine the absolute velocity of the earth through the ether by means of the interferometer. A simple form of Einstein Theory was stated with numerous illustrations, the speaker concluding by passing to a general discussion of relativity. Attendance 51.

St. Louis.—March 23, 1921, Engineers' Club. Subject: "Power Situation in St. Louis District." Speaker: Mr. L. H. Egan, President, Union Electric Light & Power Company. Attendance 135.

San Francisco.—February 25, 1921, Engineers' Club. Subject: "Practical Talk on Modern Methods of Radio Communication." Speaker: Captain C. I. Hoppough, Signal Corps, U. S. A. Attendance 104.

Schenectady.—March 18, 1921, Edison Club Hall. Subject: "Hot Cathode Devices: Their Principles and Applications." Speaker: Dr. Saul Dushman, of the Research Laboratory of the General Electric Company, Schenectady. Attendance 200.

April 1, 1921, Edison Club Hall. Subject: "The Elements of Einstein's Theory." Speaker: Professor C. L. E. Moore, of Massachusetts Institute of Technology. Attendance 260.

Seattle.—March 15, 1921. Mr. C. F. Uhden, Engineer in Charge of the Skagit River Power Project, showed a large number of very interesting lantern slides showing the nature of the upper Skagit River Valley and some of the construction work already completed. He also gave in a concise way the general features of the ultimate project and explained what the first installation would include. Attendance 85.

Spokane.—February 21, 1921, Davenport Hotel. Joint meeting with the Associated Engineers. Subject: "The Engineer and His Opportunity." Speaker: Mr. E. S. Carman, President, A. S. M. E. Attendance 37.

March 18, 1921, Davenport Hotel. Joint meeting with Associated Engineers. A four reel motion picture entitled "The Story of Petroleum." was shown. Attendance 74.

Toronto.—March 18, 1921, Toronto University. Subject: "Switching Equipment." Speaker: Mr. L. B. Chubbuck, of the Canadian Westinghouse Company. Mr. Chubbuck had collected a large number of slides illustrating switching connections and apparatus in the power houses of the Niagara Falls Power Company, the Shawinigan developments, the Hydro-Electric Power Commission of Ontario, the Ontario Power Company, and other plants. After the slides, the films which were recently presented at the Midwinter Convention of the Institute were shown, illustrating the operation of circuit breakers and fuses under abnormal overload conditions. Attendance 135.

April 1, 1921, Toronto University. Joint meeting with Ontario Section A. S. M. E. and Toronto Chapter A. S. S. T. Subject: "The Manufacture of Armco Ingot Iron and Special Steel Sheets," illustrated with motion pictures. Speaker: Mr. T. W. Jenkins, American Rolling Mills Company. Attendance 150.

April 8, 1921, Toronto University. Subject: "The Application of Acoustic Engineering to Fog Alarm Problems," illustrated. Speaker: Professor Louis V. King, McGill University. Attendance 57.

Urbana.—March 18, 1921. Subject: "The Fatigue or Progressive Failure of Metals." Speaker: Professor H. F. Moore. Attendance 82.

Vancouver.—March 21, 1921. Joint meeting with the British Columbia Technical Association. Subject: "Electric Energy Rates." Speaker: Mr. E. E. Walker, Sales Manager of the B. C. Electric Railway Co. Ltd. Attendance 36.

March 31, 1921. Subject: "1200-Volt B. C. Electric Railway Equipment." Speaker: Mr. R. L. Hall, E. E., B. C. Electric Railway Company. The paper was well illustrated with lantern slides, curves, calculations data, diagrams, etc. Attendance 26.

Worcester.—March 29, 1921. Subject: "Operation of the New England Power Company System." Speaker: Mr. A. S. Walker, Chief Load Dispatcher for new England Power Company. Mr. Walker described the development and equipment of the New England Power Company and the methods used in determining stream flow and in dispatching power load in accordance therewith. Attendance 80.

PAST BRANCH MEETINGS

Alabama Polytechnic Institute.—March 3, 1921. Subject: "The Engineer Salesman." Speaker: Mr. E. F. Pearce, of the Atlanta Office of the General Electric Company. Attendance 33.

March 31, 1921. Subject: "Electric Railways." Speaker: Mr. E. F. Sanborn. Attendance 45.

University of Arkansas.—March 15, 1921. Election of officers for spring quarter as follows: Chairman, S. E. Hollabaugh, Jr.; Vice-Chairman, Maximilliam X. Ware; Secretary, L. Gale Huggins; Treasurer, Archie Blackburn. Subjects: "A National Survey of Waste" by R. J. Horn; "Some Electrical Causes of Dust Explosions" by Jack Thompson; "Future Power Development" by R. P. Hart. Attendance 10.

Armour Institute of Technology.—April 7, 1921. Subject: "Substation Design." Speaker: Professor John A. Snow. Attendance 32.

Bucknell University.—March 16, 1921. Moving picture of the Westinghouse Company, entitled "That Little Snowflake" was shown. Attendance 125.

University of California.—March 9, 1921. Paper: "Theory and Workings of the Magnavox or Electro-Dynamic Receiver." Author: Mr. Herbert Metcalf, Magnavox Company of San Francisco. Attendance 61.

April 6, 1921. Subject: "Commercial Phases of Electric Drive." Speaker: Mr. M. Rhine, General Electric Company. Attendance 32.

University of Cincinnati.—February 8, 1921. Subject: "Flying." Speaker: Mr. H. H. Bush. Attendance 126.

February 15, 1921. Subject: "A-C. Motor Control." Speaker: Mr. E. B. Smith, General Electric Company. Attendance 40.

March 8, 1921. Subject: "A New Method for Accurate Alignment of Bearings." Speaker: Mr. T. R. Watts. Attendance 40.

March 15, 1921. Subject: "The Results of an Electrolysis Survey in West Virginia during the Summer of 1920." Attendance 65.

March 22, 1921. Subject: "Graphic Meters and What They Tell." Speaker: Mr. J. Esterline, President of the Esterline Company. Attendance 107.

March 29, 1921. Subject: "Electric Metering and Meter Departments of Central Stations." Speaker: Mr. G. C. Brown. Attendance 49.

April 5, 1921. Subject: "Electricity and Civilization." Speaker: Professor A. M. Wilson. Attendance 69.

April 12, 1921. Subject: "The Power Plant of a Paper Mill." Speaker: Mr. H. E. Hennegerin. Attendance 77.

Clarkson College of Technology.—March 15, 1921. Election of officers as follows: Chairman, M. Johnston; Secretary, L. H. Cline; Treasurer, R. W. Tozer. Attendance 23.

Clemson Agricultural College.—March 24, 1921. Subject: "George Westinghouse." Speaker: Mr. W. E. Freeman. Attendance 57.

University of Colorado.—March 24, 1921. Subject: "Electric Arc Welding," illustrated. Speaker: Mr. G. N. Robinson, of the Denver Branch of the General Electric Company. Attendance 82.

Iowa State College.—March 16, 1921. Election of officers as follows: Chairman, A. S. Egulf; Vice-Chairman, A. H. Eschbach; Secretary, A. F. Kenyon; Treasurer, C. A. Molsberry. Subject: "Electric Distribution System of the Denver Gas & Electric Company." Speaker: Professor Frank D. Paine. Attendance 51.

April 6, 1921. Joint meeting of Branches of A. I. E. E. and A. S. M. E. Subject: "The Foundry, Its Design, Construction, and Equipment for Efficient Operation." Speaker: Mr. Ferguson, of the Frank Chase Co., Inc., Engineers. Attendance 32.

University of Iowa.—March 8, 1921. Subjects: "Super Chargers for Aeroplanes" by T. Roche; "The New Brunswick Radio Station" by Allen Rockwood; "The Steinmetz Electrical Vehicle" by Charles Krause. Attendance 29.

March 21, 1921. Subject: "Railroad Electrification." Speaker: Mr. R. Owen. Attendance 22.

Kansas State Agricultural College.—March 10, 1921. Subjects: "A. I. E. E. Membership and its Advantages" by Professor Reed; "Advertisements" by Mr. E. Doming; "Radio Telephony" by Mr. G. W. Glendening. Attendance 83.

University of Kansas.—March 17, 1921. Subject: "Historical and Modern Phases of Architecture." Speaker: Professor Goldsmith. Attendance 25.

Lehigh University.—March 10, 1921. Subject: "The Superpower System, Its Answer to a National Power Policy." Speaker: Mr. William S. Murray. Attendance 289.

University of Maine.—March 10, 1921. Mr. R. M. Jocylen gave an illustrated lecture on the Panama Canal. Professor A. S. Hill talked on the Foundations which determine the future of the young engineer. Attendance 28.

Massachusetts Institute of Technology.—March 24, 1921. Subject: "Magnets and Coils," illustrated. Speaker: Mr. C. R. Underhill, of the Acme Wire Co., New Haven, Conn. Smokes and refreshments were served. Attendance 85.

Michigan Agricultural College.—March 16, 1921. Election of officers as follows: Chairman, H. L. Fleming; Secretary-Treasurer, C. M. Brown. Subject: "Report on the New York A. I. E. E. Convention Held February 16-18, 1921." Speaker: Professor M. Cory. Attendance 35.

April 12, 1921. Moving picture entitled "The Electric Giant" was shown. Professor Cory gave an interesting talk on "The Design of Turbo-Generators." Attendance 33.

University of Michigan.—March 23, 1921. Subject: "Some Applications of Electricity to Industrial Heating." Speaker: Mr. J. S. Gault. A reel of motion pictures on the construction of a 150,000 h. p. turbo-alternator was shown. Attendance 23.

April 5, 1921. Subject: "Interesting Experiences in the Application of Heavy Duty Motors." Speaker: Mr. Harry J. Fisher, of the Reliance Motor Company of Cleveland. Attendance 34.

University of North Carolina.—February 11, 1921. Subjects: "Individual Motor Drive in Print Shops," by Mr. T. Larsen; "Central Station Operation," by Mr. C. G. Mauney; "Polarity in Transformers," by Mr. M. E. Lake; "Time Limit Cutouts," by Mr. P. C. Smith. Attendance 38.

February 25, 1921. Subjects: "Construction of Transmission Lines" by Mr. G. Brown; "Controllers" by Mr. B. E. Humphrey; "Electric Ship Propulsion" by Mr. R. A. Tillman; "By-Product Coke" by Mr. C. J. Bryan. Attendance 47.

Ohio Northern University.—March 17, 1921. Subjects: "The Vacuum Tube" by Mr. L. A. Kille; "Tidal Power" by Mr. Elmer Stoker; "Remarks" by Mr. Morris Elder. Attendance 26.

April 7, 1921. Subject: "Applications of Electricity in Coal Mines." Speaker: Mr. B. L. Decker. Attendance 11.

Ohio State University.—March 11, 1921. Business meeting, followed by a talk by Professor W. A. Knight on his early electrical experiences in Columbus. Attendance 40.

April 1, 1921. Election of officers as follows: Chairman, J. O. Sherrard; Vice-Chairman, E. K. Clark; Financial Secretary, L. D. Barley; Junior Representative, R. L. Brown; Sophmore Representative, J. Fies. Subject: "Describing the Structural and Electrical Features of the new Telegraph Office of the Western Union Company at Chicago." Speaker: Mr. P. J. Howe, of the Western Union Company. Attendance 37.

Oregon State Agricultural College.—March 9, 1921. Two reels of moving pictures entitled "Big Deeds and Revelations" were shown. Attendance 35.

Pennsylvania State College.—March 10, 1921. Subject: "Shunt and Series Relays." Speaker: Mr. Woodruff. The paper of the A. E. S. C. on "National and International Standardization" was read before the Branch. Attendance 43.

University of Pennsylvania.—March 4, 1921. Subject: "Pyrometers and Their Application." Speaker: Mr. C. H. White. Attendance 41.

March 11, 1921. Subject: "Three-Electrode Vacuum Tube." Speaker: Mr. J. Mauran. Attendance 41.

University of Pittsburgh.—March 15, 1921. Subjects: "Fire Control of 12-inch Mortars" by Mr. P. O. Langgath; "Watt-Hour Meters" by Mr. J. W. Hirsch; "The Manufacture of Bakelite" by Mr. K. Appasamy. Attendance 27.

April 5, 1921. Subject: "The West Penn Power Plant at Springdale." Speaker: Mr. L. L. Pendleton. Attendance 30.

Rose Polytechnic Institute.—March 10, 1921. Subject: "Electric Furnaces." Speaker: Mr. H. A. Schwartz, of the National Malleable Castings Company. Attendance 113.

April 1, 1921. Subject: "Development of Electrical Power in Indiana Coal Fields." Speaker: Mr. J. W. Dunbar. Attendance 23.

Syracuse University.—March 4, 1921. Subject: "Automatic Telephones." Speaker: Mr. Barnes. Attendance 13.

April 1, 1921. Moving picture entitled "Romance of the Rails" was shown. Attendance 23.

April 8, 1921. Subject: "H. L. Grid Controllers." Speaker: Mr. L. M. Moore. Attendance 13.

Texas A. & M. College.—March 22, 1921. Subjects: "Recent Developments in Electrification of Battleships" by Mr. R. B. Steele; "The Whys of Railroad Electrification" by Mr. E. L. Robinson. Attendance 36.

University of Texas.—March 28, 1921. Subjects: "Fundamentals of Wireless" by Mr. J. P. Buchanan; "Spark and Continuous Wave Sets" by Mr. George Endress; "Vacuum Tubes" by Mr. George Reeves; "Wireless Communication" by Mr. C. Read Granberry; "The Talking Arc" by Mr. J. P. Buchanan. Demonstrations of apparatus. Attendance 150.

Virginia Military Institute.—March 19, 1921. Subjects: "What is Power Factor" by Mr. Blackwell; "The Induction Motor" by Mr. Harwood. Interesting comment by Col. Stewart W. Anderson on the use of the Synchronous Motor. Attendance 90.

Virginia Polytechnic Institute.—February 28, 1921. Subjects: "The Evolution of the Transformer" by Mr. W. O. Wirt; "The Early Development and Construction of the Telephone" by Professor Lee, illustrated by a set of his personal slides on the subject. Attendance 34.

March 28, 1921. Mr. W. E. Freeman, Supervisor of Commercial Training of the Educational Department, Westinghouse Elec. & Mfg. Co., gave a very interesting talk on the life and works of Mr. George Westinghouse and the advantages offered by the Westinghouse Company to the technical graduate. Attendance 59.

Washington University.—March 24, 1921. Subject: "Transmission Problems in Long Distance Telephony." Speaker: Mr. C. F. Craig, District Plant Superintendent of the St. Louis Branch of the A. T. & T. Co. Attendance 12.

State College of Washington.—March 18, 1921. Moving pictures were shown on the Hawaiian Sugar Industry and Making of Rubber Tires. Attendance 18.

University of Washington.—March 8, 1921. Subject: "Sales Engineering." Speaker: Mr. J. Clint McDougal. Attendance 24.

West Virginia University.—March 28, 1921. Subjects: "The Pointolite Lamp" by Mr. R. B. Walker; "The Electron Theory" by Mr. J. L. Hark; "Oxide Film Lightning Arresters" by Mr. A. E. LaPoe; "The New Bridge at Fairmont" by Mr. R. D. Brown. Attendance 15.

April 11, 1921.—Subjects: "Automobile Ignition Systems" by Mr. W. D. Stump; "Sterilizing by Ultra Violet Rays" by Mr. R. M. Hanks; "Limitations of High-Voltage Transmission" by Mr. R. L. Sheffer. Attendance 15.

Yale University.—April 14, 1921. Subject: "Steel Towers for Power Transmission Circuits." Speaker: Mr. W. K. Archbold, President of the Archbold-Brady Co., Syracuse. Attendance 44.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y., the employment clearing house of the Societies constituting the Federated American Engineering Societies.

Notices for the JOURNAL are not acknowledged by personal letter, but they will usually appear in the next issue that goes to press.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to EMPLOYMENT SERVICE, as above.

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

OPPORTUNITIES

RECENT TECHNICAL GRADUATE with some practical experience, preferably industrial, wanted for general instruction work in a correspondence school. Teaching experience desirable but not essential. Some engineering experience, either before or after graduation, is essential, also the ability to handle correspondence. Location New York City. X-304.

ELECTRICAL ENGINEER. An electrical engineer graduate of a high grade technical school with a year of subsequent experience in testing. The work will require a man who understands the theory and design of a-c. motors, of sizes up to 100 h. p., and who can work up the data obtained from shop tests of such motors. Location New York. X-317.

COMBUSTION ENGINEER with fuel oil experience. Location Cuba. Spanish essential. X-311.

ELECTRICAL OR MECHANICAL ENGINEER, technical graduate with two or three years practical experience in power station, substation, transmission and distribution work. The work to consist largely in analyzing construction and operation costs, preparation of contracts and estimates for future work and the preparation of special reports. Give detail of experience, references and salary expected in the first letter. Location New York City. X-316.

DRAFTSMEN (10) electrical graduates. Must be very good letterers, and be experienced in design of power house equipment, substation design and equipment, high tension line design and other electrical work associated with this class of engineering. Location Pa. X-327.

CHIEF DRAFTSMAN under age of 45 years. Experienced in electrical, civil and mechanical design for power plants, steel structures and railways, to take charge of draftsmen in engineering office. Must be diplomatic and able to supervise force and get results. Location Middle West. X-340.

ASSISTANT ELECTRICAL ENGINEERS experienced in preparations of specifications for electrical equipment and construction. Also in estimating cost and calculating stresses from designs and switches for construction of sub-stations, tension lines and power stations. Location Middle West. X-341.

DESIGNING DRAFTSMEN, civil, electrical and mechanical draftsmen, under 35 years of age, good letterers and designers. Location Middle West. X-342.

SALES ENGINEER with experience in high pressure steam piping and valve layouts. Some experience necessary with small direct and alternating current motors and circuits. Location. New York City. X-343.

SALES ENGINEER acquainted with steel mill electrical and mechanical engineers, to advise on high pressure steam and water piping and gate valve layouts. Should have some knowledge of direct and alternating current small motors and circuits. Location New York City. X-344.

SALES ENGINEERS with demonstrated selling ability to sell Elevator Guide Rail lubricator. Experience in building supply or power plant specialty lines desirable. Long residence in the city where they intend to work would be helpful. Men 25-35 would be most suitable. Territory open—Chicago, Philadelphia, Detroit and Cleveland. X-348.

YOUNG ENERGETIC MAN, who has had some training in operation of street railway, combined with some electric knowledge for position with superintendent who today looks after the operation of master mechanic, track foreman, overhead foreman, etc. as well as all the income from railway, advertising, etc. Superintendent is really local manager of entire property. Require individual who will step in between superintendent and various operating individuals above enumerated. The property consists of both city and interurban railway, city property about eight (8) miles in length and interurban about sixteen (16) miles, both double track properties, with necessary shop facilities, accounting, etc. Application by letter only giving age, education and salary. Location New York State. X-351.

ASPHALT ROOFING SALESMEN for foreign service. Men with broad practical experience both in selling and application work. X-352.

ENGINEERING DRAFTSMAN experienced in the design and development of globe gate and angle valves of more or less competitive type. Location Conn. X-361.

ENGINEER to do electrical testing in experimental department on small motors with either practical or technical training along these lines. Application by letter. Location Ohio. X-390.

YOUNG TECHNICAL MEN preferably recent graduates, with sales experience. The nature of the work is sale of electrical lines. Commission basis. Location—in and around New York City. X-391.

ELECTRICAL ESTIMATOR, who can figure on electric wiring. Big job. Careful man necessary; must be experienced. Position temporary. X-402.

ELECTRICAL FOREMAN for new P. S., looking after electrical operation and maintenance. Should have had considerable operating experience, also construction and some test. Should be man capable of advancing. Application by letter only. Location New York. X-408.

RECENT ELECTRIC ENGINEERING COLLEGE GRADUATE wanted for telephone development and research work in New York City. Capability of doing original work, broad technical training and acceptable personality are essential. Good opportunity for advancement. Give complete details regarding technical and personal qualifications. Application by letter only. Location New York City. X-418.

MECHANICAL DESIGNING DRAFTSMAN, thoroughly familiar and experienced in the design of large a-c. and d-c. motors. Must be capable of developing original ideas and handling squad of detailers. Only men with long experience considered. Position permanent. Give full details as to experience, age, nationality and salary expected. Location New Jersey. X-421.

ELECTRIC METER TESTERS. First class man. Location South Carolina. X-424.

GRADUATE ELECTRICAL ENGINEER who has had experience with General Electric, Westinghouse or similar companies for public utility company in Central America. Must be familiar with design, construction, and repairs of power plants and distribution systems. Commercial experience and Spanish also desirable. Should not be over 26 years old. Location Central America. X-425.

ELECTRICAL RESEARCH ENGINEER having thorough basic training with sufficient practical experience in electrical work to undertake important responsible problems. Familiarity with technique of alternating current work as applied in power and telephone fields very desirable. Should be capable as an executive. Work requires resourcefulness and initiative. Location near San Francisco. X-428.

THE UNITED STATES CIVIL SERVICE COMMISSION announces open competitive examinations for the following positions: Associate Electrical Engineer, at $3000 to $4000 a year; Junior Electrical Engineer, at $1500 to $2000 a year; to fill vacancies in the Bureau of Mines, Department of the Interior for duty at Pittsburgh, Pa., and in positions requiring similar qualifications throughout the United States. Also: Electrical Engineer, at $2400 to $3600 a year; Assistant Electrical Engineer, at $2000 to $2400 a year; Electrical Assistant, at $1500 to $2000 a year; to fill vacancies in the Signal Service at Large, Washington, D. C., and in positions requiring similar qualifications. Also: Sound Inspector, at $8 to $9.60 per diem, to fill a vacancy in the Bureau of Engineering, Navy Department, Washington, D. C., and vacancies in positions requiring similar qualifications. All of the vacancies are to be filled from the examinations, at the salaries listed, or at higher or lower salaries, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. Applicants should apply at once for the form desired, stating the exact title of the examination, from those listed above, to the Civil Service Commission, Washington, D. C.; the Secretary of the United States Civil Service Board, Customhouse, Boston, Mass., New York, N. Y., New Orleans, La., Honolulu, Hawaii; Post Office, Philadelphia, Pa., Atlanta, Ga., Cincinnati, O., Chicago, Ill., St. Paul, Minn., Seattle, Wash., San Francisco, Cal., Denver Col.; Old Customhouse, St. Louis, Mo.; Administration Bldg., Balboa Heights, Canal Zone; or to the Chairman of the Porto Rican Civil Service Commission, San Juan, P. R. Receipt of applications closes May 24, 1921.

MEN AVAILABLE

DRAFTSMAN ENGINEER experienced on oil well machinery; manufacture of 6 in. shells and equipment for manufacturing same; general construction in large asphalt refinery; graduate electrical engineer 1915. Accustomed to team work. Wants to connect with company affording excellent opportunity for service growth and responsibility. E-2629.

GRADUATE ELECTRICAL ENGINEER (1918). Registered patent attorney; with executive ability. Exceptional industrial training. Qualified as chief engineer and patent attorney to small manufacturing concern or assistant to chief engineer or general manager of large one. Employed at present. Available 30 days. Minimum $3500. E-2630.

YOUNG MAN, age 24; single, desires position as electrician with some desirable firm, where efforts will be considered. One year of practical construction work in electrical power devices. Now available and will consider any place in U. S. Good references. Associate A. I. E. E. E-2631.

YOUNG ELECTRICAL ENGINEER, practical; age 23; American. Not afraid to learn or work. Have you a position for me? Seven years experience on a-c. and d-c. engineering, etc. Attended School of Eng. Milwaukee. Assoc. A. I. E. E., Mem. N. A. S. E. and A. A. A. S. Prefer South or West. Available immediately. E-2632.

ELECTRICAL ENGINEERING graduate; age 25; married, with engineering laboratory, sales and executive experience, desires connection with industrial, construction, or consulting engineering firm. Available on short notice. E-2633.

GRADUATE ELECTRICAL ENGINEER with eight years construction and operating experience with public utility companies. Desires executive work such as assistant to manager of several properties. Correspondence solicited. E-2634.

ELECTRICAL ENGINEER, University graduate; Assoc. A. I. E. E., age 23. Two years experience in generation and transmission. Desires position preferably high tension transmission. Location North America or Europe. E-2635.

ELECTRICAL AND MECHANICAL ENGINEER desires responsible position with reliable company in foreign field. Technical graduate; two years broad construction experience with steel corporation, two years with public utilities; power and substation construction, estimating, valuation, and general engineering work. Familiar with transmission and distribution practise. E-2636.

ELECTRICAL ENGINEER age 36; married. Ten years General Electric Co. Test Dept; one year drafting; one year installation of steam turbine; one year electrical maintenance, five years assistant foreman and foreman of mining low assembly department General Elec. Co. Erie, Pa. Two years 1st Lieut. Engineers. E-2637.

PROFESSOR OF ELECTRICAL ENGINEER, University of Wisconsin graduate, A. B., E. E. age 34. Seven years experience in electrical construction. Three years head of electrical engineering department of western university. Desires position as professor in large middle western or western university with opportunity of developing consulting practise. Minimum salary $3500. E-2638.

ELECTRICAL ENGINEER, age 32; single. Nine months testing experience with Westinghouse Elec. & Mfg. Co., four years with large electric railway company. Experience includes electrolysis investigation, cable inspection, and solution of problem pertaining to electric traction and power plant operation. E-2639.

EXPERIENCED RESEARCH PHYSICIST. Fifteen years industrial research in Bureau of Standards and in two of largest manufacturing concerns; eight years in charge of highest grade of research. Experienced in organization and administration of research work. Salary $6000. E-2640.

ELECTRICAL ENGINEER. Four years experience with large electrical manufacturer in testing and railway engineering departments. Technical graduate. Position wanted with electric railway company where duties will concern electrical equipment of both power house and rolling stock. Available in 30 days. Salary $250. E-2641.

EX-ARMY OFFICE (Major) having had eighteen years experience in telephone engineering, cable installations, d-c. Light and Power systems; also as executive and office manager, desires to connect with manufacturer or firm. Can invest limited amount of capital in profitable business. E-2642.

MECHANICAL ENGINEER, age 31. Eight years experience in mechanical and electrical engineering work including design, construction and maintenance of hydroelectric installations; standardization of shop manufacturing methods in metal trades; purchasing; office management. Expert in electric welding. Sound business training. Desires position of responsibility; location immaterial. References all past employers. E-2643.

YOUNG ELECTRICAL ENGINEER, Associate A. I. E. E.; age 23; single. Six years experience in industrial and power plant work, desires to make connection with industrial power plant construction or general consulting concern. At present employed as engineering draftsman of large engineering corporation. Available at once. Location no object. E-2644.

INSTRUCTOR OR ASSISTANT PROFESSOR. University graduate; E. E. having some teaching experience and three years public utility experience, seeks position with educational institution next fall. Wide awake and interested young man, age 25; married. Assoc. A. I. E. E. Prefer location central or Western U. S. with institution offering satisfactory permanent position. E-2645.

ELECTRICAL ENGINEER, age 25; graduate M. I. T. desires change offering position with broader opportunities. Two years

office and field work with large power corporation. Salary $2500. Available on short notice. E-2646.

EXECUTIVE, with 12 years broad engineering experience and sound business training, desires executive position to which engineering knowledge is essential, and which has a future sufficiently attractive to warrant change. Assoc. A. I. E. E. Assoc. Mem. A. S. M. E. Age 34; married. Location immaterial. Present salary $6000. E-2647.

ENGINEER AND EXECUTIVE. Five years practical experience doing graduate work at present, desires employment during afternoons, as assistant to executive. Has specialized on industrial problems of an economic nature. E-2648.

MECHANICAL ENGINEER can sell a good product. Sales experience with adequate compensation desired. Age 30; Cornell graduate. Six years industrial plant design; seven months construction; three years in army. Special knowledge; oil industry; paper and pulp business. Available May 1st. E-2649.

TECHNICAL GRADUATE, two years Westinghouse test; two years responsible construction work with large operating company; two years superintendent of power company in city of 70,000. Varied power sales experience. Available on two months notice as manager of power sales or assistant to general manager of power company. Salary $3000. E-2650.

ERECTING ENGINEER, age 34; technical education. Ten years construction department General Electric Co. power station and electric railways installation and operation; four years supervision of electrical installations on all types cranes, car dumpers, coal, and ore bridges, and coal handling machinery. Best references furnished. Available immediately. Assoc. A. I. E. E. E-2651.

ELECTRICAL ENGINEER, technical graduate 1907. Four years railway electrification; three years on large industrial application; two years with Central Station Co., five years as electrical engineer with large street railway with which I am now employed; including four years experience with application of automatic substations. E-2652.

ELECTRICAL ENGINEER, graduate M. I. T., two and one half years experience including General Electric test, wishes position in New York City. Character and education the best. Can arrange personal interview any time. E-2653.

ELECTRICAL-MECHANICAL ENGINEER AND EXECUTIVE. Twelve years practical experience; design construction, operation power plants, industrial equipment, outside construction. University graduate, Assoc. A. I. E. E. Best of references. Excellent reason for change. Only position with room at top considered. Married. West preferred. Present salary $3900. E-2654.

GRADUATE ELECTRICAL ENGINEER, B. S. degree, with experience in wireless, motor and generator test work desires position on test work or as assistant designing engineer. Thoroughly familiar with above named work. Energetic and reliable; good references furnished. E-2655.

GRADUATE ENGINEER with 15 years experience in design, construction and combustion work with public service and private power plants also purchasing and sales experience, desires permanent position in executive work with reliable company. Age 37; married. E-2656.

ELECTRICAL MECHANICAL ENGINEER, University graduate; age 25. One year with large electric railway and light company; one year of business experience. Desires connection with sales engineering or industrial concern. Location preferred, Michigan or bordering states. E-2657.

GRADUATE ELECTRICAL ENGINEER, Member A. I. E. E. Twelve years experience in marine electrical work, and manufacturing. Former Capt. of Engineers in World War. Location in or near New York City preferred. Past five years in responsible charge of work. E-2658.

GENERAL FOREMAN AND CHIEF ELECTRICIAN. Ten years experience on construction, operation and maintenance of electrical and mechanical equipment; also thorough knowledge of gas engines. Instructor while in United States Army and Inspector for General Electric Company. Good organizer and can handle large force of men. Wishes position as head of maintenance department, chief electrician or plant foreman. Married; age 30. Salary $3000. E-2659.

ELECTRICAL MECHANICAL ENGINEER, graduate Cornell and Pennsylvania State. Seven years experience design construction, operation, management, large power developments, high tension, distribution hydraulics, thermodynamics, contracts, specifications, reports, valuation, costs, efficiency work, desires connection with future where executive and engineering ability are requisites. Best references. Salary $4800. E-2660.

ELECTRICAL ENGINEER, age 39; married; technical graduate. Fifteen years experience in transmission and distribution; hydro and steam station design and installation. For past three years with consulting engineering firm. Present salary $3000. Available in two weeks notice to present employers. E-2661.

TECHNICAL GRADUATE in industrial electrical engineering, desires position as assistant in electrical engineering department of railroad or operating company. Two years General Electric test; five years railroad operating and construction experience; one and half years in engineering department of large electrical manufacturing concern. Single; age 35; minimum salary $1800. E-2662.

TECHNICAL GRADUATE, age 22; single, desires position in electrical industry, preferably Central Station, with opportunity to learn and advance. Not afraid of work. Available about June 15th; references. E-2663.

ENGINEERING ACCOUNTANT, graduate electrical engineer, ten years experience in design, manufacture, test, theory and cost of insulated wires and cables, seeks position with manufacturing firm, consulting engineer, or firm of cost engineers. Is especially desirous of doing cost and production engineering in the above or any other line of work. E-2664.

ELECTRICAL ENGINEER, age 32; married. Sixteen years experience, correspondence graduate desires connection with future. Familiar with hydroelectric, telephone, construction, also three phase industrial maintenance. At present employed by large maining company as electrical engineer. Available sixty days. Prefer mining connection in Mexico, South or Central America. Salary $3000. E-2665.

ELECTRICAL ENGINEER, age 27; college graduate (B. S.) and technical school graduate (E. E.). Three years experience along broad engineering lines, power plants, laboratory research, electrical engineering works. Location immaterial. E-2666.

EXECUTIVE. Electrical engineer, long experience sales and export executive in wire and cables. Also broad business training including purchasing, banking credits and shipping. Available immediately. E-2667.

ENGINEERING EXECUTIVE. Graduate electrical engineer, Harvard. Captain Coast Artillery; age 34. Extensive experience in construction and operation. Desires permanent position with utility or industrial company where wide engineering experience will be valuable. Salary $3000. Available on short notice. New York or New England preferred. E-2668.

ELECTRO-MECHANICAL ENGINEER. Cornell; age 26; five years broad experience including two years General Electric Co. test. Desires position near New York City requiring good engineering sense and business ability combined, with good opportunity for advancement. Small growing concern preferred. E-2669.

GRADUATE ELECTRICAL ENGINEER of Robert College, Constantinople, wishes position with electrical engineering company in America. Will receive degree in June 1921. E-2670.

ELECTRICAL MECHANICAL ENGINEER, technical graduate; four years general factory maintenance and construction. Good executive; age 27. Sales proposition considered. Excellent references. Wants permanent position in any locality. E-2671.

ELECTRICAL ENGINEER, technical graduate; eight years experience in estimating, designing and installing central and substation buildings and equipment; transmission and distribution problems; electric railway and central station operation; Associate A. I. E. E. Desires permanent connection where ability and personality will gain advancement. E-2672.

DISTRICT MANAGER AND SALES ENGINEER. Technical graduate; electrical and mechanical. Age 34; married; available upon reasonable notice to build up business in industrial machinery in eastern Pennsylvania, Maryland and Virginia with headquarters in Philadelphia. Eight years experience in territory with wide acquaintance in steel mill and kindred industries. E-2673.

BUSINESS MAN. Position wanted on staff of financial, underwriting or analytical organization to investigate commercial, technical and scientific soundness of industrial, public utility and other business enterprises. Executives of broad business experience. E-2674.

ELECTRICAL AND MECHANICAL ENGINEER, technical graduate. 1915; broad exerience in design, supervision of construction, maintenance, and operation of complete hydroelectric and steam power plants, substations, and overhead and underground transmission systems. Familiar with estimating, specifications, purchasing and supervision of

drafting. Position desired with consulting engineer, public utility or contractor. E-2675.

Electrical Engineer, technical graduate; age 38; married. Fifteen years experience with best operating and engineering firms. Successful record as testing and starting engineer. At present engaged as field engineer on construction of large central station. Desires position of responsibility with central station organization or engineering firm. Present salary $4200. Assoc. A. I. E. E. E-2676.

Experimental Engineer, graduate E. E. 1917. Two years instructor in power engineering, experienced in power plant and gas producer equipment tests, desires position where permanence, fair salary and opportunity for advancement are combined. Available July 1st. E-2677.

Mathematical Electrical Engineer with considerable practical experience and some teaching experience will consider assistant professorship. E-2678.

Electrical Superintendent or maintenance engineer. Seven years industrial engineering; five years experience in manufacture and testing of wires and cables; desires connection with concern which appreciates results. Correspondence or interviews solicited. E-2679.

Electrical and Mechanical Engineer technical graduate; seventeen years experience on design, construction and operation of power plants and industrial power systems. High grade man of unusual ability who has held executive positions on projects of great magnitude. Available soon. Desires position with power company or industrial concern. E-2680.

Electrical Engineer, technical graduate; married; age 29. General Electric test experience. Electrical precipitative work. Four years experience installing and operating plant equipment. Wide experience on chemical plant equipment. Desires position as assistant superintendent or plant engineer. Salary $3000. Available on short notice. E-2681.

Sales Engineer with extensive experience in both domestic and foreign fields wishes to develop a few high grade non-interfering accounts in New York, metropolitan district and abroad, on commission basis. Electrical and mechanical products of common use especially desired. E-2682.

Graduate Electrical Engineer, ten years experience in industry, including central station industrial research, electrolysis prevention and rate studies. Also five years teaching electrical engineering. At present head of department. Desire industrial position for summer or permanently, or teaching with opportunity for research work. Member A. I. E. E. Present salary over $3400. E-2683.

Electrical Engineer, desires position as superintendent of operation and maintenance in hydroelectric plant. Five years experience as assistant to superintendent of large hydroelectric system. Experience covers construction, operation and maintenance of generating station, outdoor and indoor substations, high voltage overhead and underground transmission and general executive work. E-2684.

Chief Operating Engineer or mechanical superintendent with broad experience in safe and economical operation, maintenance of electric light, power and refrigerating plants; also large factories and buildings, having first class engineering and electrician's licenses. At present holding similar position, desires to make a change. Location anywhere before August 1st. E-2685.

Electrical and Mechanical Engineer, age 30. Ten years practical experience with mining companies as chief electrician, central stations as electrical engineer and general operation, maintenance and construction of industrial plants. At present employed, but will be available June 1st. Position as maintenance engineer of industrial plant preferred. Salary $3000. E-2686.

Technical Graduate with ten years experience in field, office and laboratory engineering with power plant equipment and electrical precipitation processes. Sales and patent experience. Desires position as development engineer or in executive capacity. E-2687.

Technical Graduate in electrical engineering, age 25; single; wishes connection with engineering, manufacturing or light and power company, affording opportunity for advancement Little experience. Locate anywhere. Available immediately. E-2688.

SQUIRES, JOHN H., JR., Electrical Testing Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1342 Penn Ave., Wilkinsburg, Pa.
STANDERWICK, REGINALD G., Asst. Engineer, General Electric Co., Lynn; res., 26 Rock Ave., Swampscott, Mass.
STANSEL, WALTER G., Signal Draftsman, Elgin, Joliet & Eastern Railway Co., 404 Joliet National Bank, Joliet, Ill.
STROMAN, CHARLES H., Watch Engineer, Elmira Water, Light & Railroad Co.; res., 48 Grove St., Elmira, N. Y.
SULLIVAN, RICHARD W., Supervisory Engineer, New England Tel. & Tel. Co., Boston; res., 5 Walker St., W. Roxbury, Mass.
SWARTZ, WILL E., Superintendent, Dunnville Hydro System Dunnville, Ont., Canada.
SWEET, EVERELL S., Construction Engineer, Condit Electrical Mfg. Co., Boston; res., 4 Ellsworth Ave., Cambridge, Mass.
TAGAWA, NOBUO, Electrical Engineer, Daido Hydro-Electric Power Co., Nagoya, Japan; Takata & Co., 50 Church St., New York, N. Y.
TANAKA, MAMORU, Engineer, Mitsubishi Shoji Kaisha, Ltd., Marunouchi, Tokio, Japan.
TARDY, LEO H., Chief Electrician (Radio), U. S. Navy, Navy Dept., Washington, D. C.
TEGEL, JOHN P., Draftsman, Commonwealth Edison Co.; res., 4256 N. Sacramento Ave., Chicago, Ill.
TEMPLETON, LEUMAS B., JR., Operating Force, Washington Water Power Co., Long Lake, Reardan, Wash.
THOMAS, EDWARD F., Electrical Engineer, Johns-Manville, Inc., Milwaukee, Wis.
THOMAS, HAROLD P., Test Inspector, Lincoln Electric Co.; res., 5808 Quinby Ave., Cleveland, Ohio.
THOMAS, J. I., Erecting Engineer, York Mfg. Co.; 131 E. Cottage Place, York, Pa.
*THOMPSON, HAROLD W., Relay Inspector, Power Construction Co., res.; 20 Catharine St., Worcester, Mass.
THORRY, JOHN, Telephone Equipment Engineer, Western Electric Co.; 463 West St., New York, N. Y.
TIMMINS, WALTER J., Asst. Chief of Research Laboratory, Edison Storage Battery Co.; res., 353 Central Ave., Orange, N. J.
TIVY, GEORGE S., JR., Salesman, Pan Electric Mfg. Co., 735 S. 4th St., St. Louis, Mo.

TODD, MILO EUGENE, Instructor, Electrical Engineering, University of Minnesota, Minneapolis, Minn.

TRADUP, ALBERT, Electrical Engineer, with American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

TREAT, HUGH P., Stores Manager, Western Electric Co., 680 Folsom St., San Francisco, Calif.

*TROTH, RAYMOND H., Radio Inspector, U. S. Navy Yard; res., 3350 N. 18th St., Philadelphia, Pa.

TUERPÉ, ELLIS R., Testing Dept., Fort Worth Power & Light Co., Fort Worth, Texas.

TUNE, EDWARD EMMETT Engineer, Stromberg-Carlson Telephone Mfg. Co., 1050 University Ave., Rochester, N. Y.

TUNIS, HENRY C., Electrical Construction Foreman, Engineering Dept., Public Service Electric Co.; res., 54 Wakeman Ave., Newark, N. J.

TURNBULL, JOHN, Chief Electrician, Genasco Refinery; res., 1531 4th St., Madison, Ill.

TWINING, JOSEPH LaVERNE, Supervisor of Transmisson, Pacific Tel. & Tel. Co., Telephone Bldg., Spokane, Wash.

TWOGOOD, ARCHIE J., Dean, Engineering Schools, Oregon Institute of Technology; res., 1076 Lambert Place, Portland, Ore.

ULVAD, JOHANNES, Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; The Westinghouse Club, Wilkinsburg, Pa.

UNANGST, EARLE G., Inspection Dept., Western Electric Co., 104 Broad St., New York; res., 66 Greene Ave., Brooklyn, N. Y.

VAN HOOK, L. N., Electrical Engineer, Power Dept., United Railways Co., 3869 Park Ave., St. Louis, Mo.

VAN STEENBURGH, W. R., Salesman, The Okonite Co., 501 5th Ave., New York, N. Y.

VAN WINKLE, FRANK H., Telephone Engineer, New York Telephone Co., 25 Dey St., New York, N. Y.; res., 47 Duncan Ave., Jersey City, N. J.

WADIA, D. A., Sub-Division Officer, Electrical & Mechanical, Military Works Service, Mistry Bldg., "B" Block, Balaram St., Grant Road, Bombay, India.

WALKER, HARRY C., Student, Toll Line Plant Dept., Southern Bell Tel. & Tel. Co., 57½ S. Pryor St., Atlanta, Ga.

WATERS, JAMES S., JR., Instructor in Engineering, The Rice Institute, Houston, Texas.

WEATHERALL, ESLEY C., Fieldman, Pacific Tel. & Tel. Co., 1102 Tel. Bldg., Portland, Ore.

WEBB, LOREN G., Load Dispatcher, Wisconsin-Minnesota Light & Power Co.; res., 222 Broadway St., Eau Claire, Wis.

WEIR, WILLIAM, Asst. Electrical Engineer Cia de Tranvias, Luz y Fuerza, Apartado 41, Puebla, Mexico.

WELLS, WARD E., Foreman Electrician, Pennsylvania Water & Power Co., Holtwood, Pa.

WESTERFIELD, MILO H., Cadet Engineer, Public Service Electric Company of New Jersey, 71 Murray St., Elizabeth, N. J.

WESTON, CYRIL L. L., Telephone Engineering Dept., Equipment Div., Northern Electric Co., Ltd., Montreal; res., Alpha Cottage, Chateauquay Basin, Que., Canada.

WEYANDT, ALBERT C., General Engineering Dept., Westinghouse Elec. & Mfg. Co.; res., 518 Franklin St., E. Pittsburgh, Pa.

WHEALY, WILFRED, Electrical Tester, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1416 Elm Ave., Wilkinsburg, Pa.

WHEATLEY, RUSSELL H., Student Engineer, Testing Dept., General Electric Co.; 707 South Ave., Schenectady, N. Y.

WHEELER, PAUL V., Resident Manager, Link & Belt Co., 429 Kirby Bldg., Cleveland, Ohio.

*WILKINS, MALCOLM L., Meter Dept., & Electrical Expert, Twin State Gas & Electric Co.; res., 261 Washington St., Dover, N. H.

WILLARD, SHERWOOD H., Building Engineer, Western Electric Co., Inc., 463 West St., New York, N. Y.

WILSON, CHARLES H., Electrical Tester, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 518 Todd St., Wilkinsburg, Pa.

WIMMER, JOSEPH, Clerk & Division Transmission Engineer, Pacific Tel. & Tel. Co., 409 Seaboard Bldg., Seattle Wash.

WINEMILLER, PRICE L., Sales Engineer, Stromberg-Carlson Telephone Mfg. Co., Kansas City, Mo.

WOODS, WILLIAM H., Asst. Engineer, Distribution Dept., Toronto Hydro-Electric System; res., 507 Brunswick Ave., Toronto, Ont., Canada.

*WORLEY, IVAN H., Paper Mill Engineer, Minnesota & Ontario Paper Co., International Falls, Minn.

WRIGHT, HARRY H. L., Checking Draftsman, Shepard Electric Crane & Hoist Co., Montour Falls, N. Y.

WYATT, JOSEPH A., District Supt., New York Telephone Co., 256 Franklin St., Hempstead, N. Y.

YOST, CHARLES Z., Engineer, Pacific Gas & Electric Co., 445 Sutter St., San Francisco, Cal.

YOUNG, LOUIS T., Electrical Draftsman, Kelman Electric & Mfg. Co., Los Angeles; res., 469 W. Oak St., Glendale, Calif.

ZIEHL, WILLIAM J., Supt., Croker Electric Co., 22 W. 30th St.; res., 1111 Quincy St., New York, N. Y.

ZINTER, JULES A., Electrical Teacher, Arsenal Technical High School; res., 2705 E. St. Clair St., Indianapolis, Ind.

ZOBEL, MAURICE L., Foreman, Fire control test room, Sperry Gyroscope Co., 40 Flatbush Ave. Extension, Brooklyn; res., 437 Home Ave., Rosebank, N. Y.

Total 418.

*Former enrolled students.

ASSOCIATES REELECTED APRIL 8, 1921

CRAMER, HARRY P., Asst. Engineer, Portland Railway, Light & Power Co., Electric Bldg., Portland, Ore.

FOULKROD, RAYMOND, Engineering Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

HAYNES, WALTER, Principal, Oregon Institute of Technology, Portland, Ore.

MUIRHEAD, JAMES, Government Inspector of Electrical Energy, Province of British Columbia, Provincial Court House, Vancouver, B. C.

REDING, HENRY W., Head of Electrical Dept., Atlanta Office, Lockwood, Greene & Co., 1530 Healey Bldg., Atlanta, Ga.

WICKS, ERNEST B. E., Electrical Engineer, Rangiora Borough Council, Rangiora, N Z.

WILLMANN, WILLIAM F., Electrical Engineer, Boston Edison Co., 39 Boylston St., Boston, Mass.

MEMBERS ELECTED APRIL 8, 1921

ADAMS, CALVIN J., Local Engineer, Syracuse Office, General Electric Co.; res., 969 Lancaster Ave., Syracuse, N. Y.

BARTMESS, MEIGS W., Chief Electrical Engineer, A. B. Products Division, The National Screw & Tack Co., Cleveland, Ohio.

DICK, WALTER R. H., Electrical & Commercial Engineer, International General Electric Co., 83 Cannon St., E. C., London, Eng.

HILDEBRAND, LEE E., Electrical Engineer, General Electric Co.; res., 24 Baker St., Lynn, Mass.

HOVEY, FRANK A., Electrical Engineer, Cooley & Marvin Co., 15 Ashburton Place, Boston, Mass.

KING, HARRY M., Electrical Supervisor, Ontario Power Co., Niagara Falls, Ont., Canada.

KOPPITZ, CARL G., Vice-President & Chief Engineer, Railway & Industrial Engineering Co., Greensburg, Pa.

LUNN, ARTHUR W., Sales Engineer, General Electric Co., 671 Broad St., Newark, N. J.

MacCALLUM, CLARENCE, Electrical & Mechanical Engineer, T. Howard Barnes, 17 Battery Place, New York, N. Y.

MORGAN, CHARLES H., Manager, Northern Iowa Gas & Electric Co., Humboldt, Iowa.

NICHOLSON, FRANK C., Electrical Engineer, Lehigh & Wilkes-Barre Coal Co.; res., 125 Barney St., Wilkes-Barre, Pa.

RICHARDSON, STANLEY M., Asst. Operating Engineer, (Power), Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Canada.

FELLOW ELECTED APRIL 8, 1921

THORESEN, JETMUND J., Chief Engineer, Elektricitets Bilsynet, 1st Dist., Pilestredet 27, Kristiania, Norway.

TRANSFERRED TO GRADE OF FELLOW

ACKER, ALBERT J., Electrical Engineer of Shaw Crane Works for Manning, Maxwell & Moore, Inc., Muskegon, Mich.

EWING, DRESSEL D., Professor of Electric Railway Engineering, Purdue University, Lafayette, Ind.

FINLAY, WALTER S., Jr., Vice-President, American Water Works & Electric Co., New York, N. Y.

MACLACHLAN, WILLS, Electrical Engineer, Toronto, Ontario.

MOORE, EDWARD T., Electrical Engineer, Halcomb Steel Co., Syracuse, N. Y.

TRANSFERRED TO GRADE OF MEMBER

ABBOTT, LEWIS W., Supervisor of Equipment, New England Tel. & Tel. Co., Boston, Mass.

BARNES, HAROLD B., Chief Engineer, Golden Fleece Mining & Milling Co., Denver, Colo.

BEAUCHAMP, LEON, Vice-President and Chief Engineer, The Solex Co. Ltd., Montreal, Quebec.

BRADLEY, HAROLD H., Commercial Engineer, Latin American Sales Dept., International General Electric Co., Schenectady, N. Y.

BROWN, GEORGE N., District Manager, Pittsburgh Transformer Co., New York, N. Y.

COOPER, CHARLES P., General Manager, Ohio Bell Telephone Co., Cleveland, O.

DeFOREST, CORNELIUS W., Manager, Electrical Dept., Union Gas & Electric Co., Cincinnati, O.

FORGEE, FREDERICK A., Consulting Engineer, New York, N. Y.

HOOD, JOHN, Local Engineer, General Electric Co., San Francisco, Cal.

JONES, PHILIP C., Electrical Engineer, Goodyear Tire & Rubber Co. of California, Los Angeles, Cal.

KEARNS, J. EDWARD, Electrical Engineer, General Electric Co., Chicago, Ill.

KELLEY, WILL G., Overhead Engineer, Commonwealth Edison Co., Chicago, Ill.

LEACOCK, GEORGE D. Y., Sales Manager, Moloney Electric Co. of Canada, Ltd., Toronto, Ont.

MEYERHERM, CHARLES F., Engineer, Albert F. Ganz, Inc., New York, N. Y.

MOLONEY, T. O., President, Moloney Electric Co., St. Louis, Mo.

PATTERSON, JAMES G., Staff Engineer, New England Tel. & Tel. Co., Boston, Mass.

SCHIRTZINGER, LEO, District Manager, Century Electric Co., Cincinnati, O.

SPEIGHT, HERBERT, Superintendent of Power, Granby Consolidated Mining, Smelting & Power Co. Ltd., Anyox, B. C.

WEBER, CORNELIUS G., Assistant Engineer, Vaughn & Meyer, Milwaukee, Wis.

YOUNG, ROWLAND L., Power Engineer, Dept. of Development & Research, American Tel. & Tel. Co., New York, N. Y.

ZEHR, VRATISLAV A., Consulting, Designing, and Constructing Engineer, Pekin, Ill.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meetings held April 1, and 14, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

BURKETT, CHARLES W., Chief Engineer, Pacific Telephone & Telegraph Co., San Francisco, Cal.
CHUBB, LEWIS W., Manager, Radio Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
CONRAD, NICHOLAS, J., Secretary-Treasurer & Manager, Schweitzer & Conrad, Inc., Chicago, Ill.
DAVIES, CHARLES E., General Traffic Superintendent, Canadian National Telegraphs, Toronto, Ont.
NEWBURY, FRANK D., Manager, Power Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
REED, HARRISON P., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
SMITH, ERNEST F., Superintendent of Substations, Commonwealth Edison Co., Chicago, Ill.
THORNTON, FRANK, JR., Manager, Electric Heating Engineering Dept., Westinghouse Elec. & Mfg. Co., Mansfield, O.

To Grade of Member

ANDERSON, E. R., Electrical Engineer, Supply Dept., General Electric Co., Schenectady, N. Y.
ATKINS, CHARLES G., Consulting Engineer, Chicago, Ill.
BELLINGER, W. F., Asst. Supt. Operations, Tests, & Repairs, Atlanta Railway & Power Co., Atlanta, Ga.
BRUBAKER, HENRY S., Construction Engineer, West Penn Power Co., Pittsburgh, Pa.
CELLAR, GEORGE A., General Supt., of Telegraph, Pennsylvania System, Philadelphia.
GOLDBERG, MAXIMILIAN M., Inventor, National Cash Register Co., Dayton, O.
GRIMSLEY, A. H., General Manager, Virginia Western Power Co., Clifton Forge, Va.
HALL, MARTIN S., Superintendent, Electrical Dept., Mathieson, Alkali Works, Saltville, Va.
HERSHEY, HARRY E., Telephone Engineer, Automatic Electric Co., Chicago, Ill.
KIDDER, HARRY A., Supt. of Motive Power, Interborough Rapid Transit Co., New York.
KNIGHT, ROBERT, Estimating Engineer, Canadian General Electric Co., Toronto.
LEFEVER, ORLAND L., General Supt., Northwestern Electric Co., Portland, Ore.
LOBECK, ADOLF J., Asst. Supt., Bronx District, N. Y. Edison Co., New York, N. Y.
MILBURN, WILLIAM R., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
NEBLETT, HERSCHEL W., Asst. Electrical Engineer, Steel & Tube Co. of America Chicago, Ill.
NICHOLSON, CHARLES M., Supt., Electrical Dept., Allis-Chalmers Mfg. Co., Milwaukee.
REDING, HENRY W., Head of Electrical Dept., Atlanta Office, Lockwood Greene & Co., Atlanta, Ga.
SKINNER, MERRILL E., Electrical Designing Engineer, Transformer Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
SNIFFIN, EDWARD H., Manager, Power Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
THOMPSON, ROSS E., Manager, Deming Ice & Electric Co., Deming, N. M.
VANDERPOEL, WILLIAM K., General Supt. of Distribution, Public Service Electric Co., Newark, N. J.
WILLMANN, WILLIAM F., Electrical Engineer, Edison Electric Illuminating Co., Boston.
WOODRESS, JAMES L., Sales Manager, Century Electric Co., St. Louis, Mo.
YOUNG, H. W., President, Delta-Star Electric Co., Chicago, Ill.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before, May 31, 1921.

Albrecht, Edwin H., Portland, Ore.
Anderson, Burton E., Oakland, Cal.
Anderson, Clifford N., W. Lynn, Mass.
Armitage, Melville, Peterboro, Ont.
Armstrong, A. H., Boston, Mass.
Bachert, Homer A., Allentown, Pa.
Bacon Roy R., White River, Ont.
Barends, Raymond E., Schenectady, N. Y.
Barrett, J. Nicolson, Cleveland, Ohio
Bartlett, Edwin N., N. Oxford, Mass.
Batcheler, Fred H., Madison, Wis.
Becker, James H., Cambridge, Mass.
Bertram, George M., Toronto, Ont.
Blackmar, Ray C., Portland, Ore.
Bond, Frank B., St. Anselme Sta., Dorchester Co., P. Q.
Borelli, Aurelio, Schenectady, N. Y.
Borshneck, C. Frank, Pittsburgh, Pa.
Bredberg, S., (Member), Schenectady, N. Y.
Bridger, Leo J., Denver, Colo.
Bryant, E. P., Saugus, Cal.
Burke, Francis X., New York, N. Y.
Burr, Henry B., Milwaukee, Wis.
Burtt, Robert B., E. Pittsburgh, Pa.
Carmichael, D. Allister, Toronto, Ont.
Carr, James A., New York, N. Y.
Carroll, Franklin O., Boston, Mass.
Carter, William L., Peterboro, Ont.
Caton, John J., Easton, Pa.
Chase, Leland H., Brooklyn, N. Y.
Christie, Donald R., Harrisburg, Pa.
Clymer, Harold B., Trenton, N. J.
Cockrill, Sterling B., Wilkinsburg, Pa.
Cole, Ira E., New York, N. Y.
Connors, Leonard M., Peterboro, Ont.
Cotton, Robert S., Peterboro, Ont.
Cramblet, Paul K., Chicago, Ill.
Crowder, Charles F., Allentown, Pa.
Davis, Sidney E., Philadelphia, Pa.
DeLanty, Benjamin F., Pasadena, Cal.
Denike, Robert E., New York, N. Y.
Derr, Edgar M., Easton, Pa.
Desai, B. C., Schenectady, N. Y.
Deutscher, Harry O., St. Louis, Mo.
Dilts, Chester W., Milwaukee, Wis.
Dovjikov, Alexander, Pittsburgh, Pa.
Duncan, A. S. Allentown, Pa.
Elmen, Gustaf W., (Member), New York, N. Y.
Emich, Harris C., Baltimore, Md.
Engel, Nathan L., (Member), Montreal, Que.
Eulenberger, Charles E., Schenectady, N. Y.
Faron, Frank A., Schenectady, N. Y.
Farrer, Henry E., New York, N. Y.
Files, Glenn W., Chicago, Ill.
Floeting, Edward R., New York, N. Y.
Flynn, P. Leo, Baltimore, Md.
Freer, George B., Jr., Utica, N. Y.
Fritz, Edwin H., Derry, Pa.
Fulmer, William A., Philadelphia, Pa.
Gerrish, Seldon W., Utica, N. Y.
Gibbons, Wiliam J., New York, N. Y.
Goob, Charles F., Baltimore, Md.
Goranson, George V., Allentown, Pa.
Grady, Frank R., Allentown Pa.
Grant, Charles E., Peterboro, Ont.
Greenamyer, Merle R., Pittsburgh, Pa.
Guthery, Marshall F., (Member), Allentown, Pa.
Hagan, H. David, Harrisburg, Pa.
Hanley, Edward L., Milwaukee, Wis.
Harman, Edwin N., Geneva, N. Y.
Hawley, Curtis B., Salt Lake City, Utah.
Held, Edward F., Bridgeport, Conn.
Hendrie, Robert A., Denison, Texas
Hotze, John W., Chicago, Ill.
Howard, Elmer F., Marion, Ill.
Howes, John C., Jr., Lynn, Mass.
Jacoby, S. Clifford, Pawtucket, R. I.
Jenks, Clifford W., Bedford, Ohio
Jones, Albert F., Denver, Colo.
Jones, John L., St. Louis, Mo.
Kaas, Hans P., New York, N. Y.
Kennard, Rollin, Great Falls, Mont.
Kettenhofen, Leo J., Chicago, Ill.
Kingsbury, William S., Bellefontaine, Ohio
Kline, E. D. G., Allentown, Pa.
Knoblock, William, Philadelphia, Pa.
Launder, John E., (Member), Kansas City, Mo.
La Barr, Myron C., New York, N. Y.
Lane, Elijah R., Chicago, Ill.
Law, Edgar D., Wilkinsburg, Pa.
Lendman, Alfred N., Kenosha, Wis.
Leonard, James G., Schenectady, N. Y.
Lyman, Van Allen, San Francisco, Cal.

Voltage and Current Harmonics Caused by Corona

BY F. W. PEEK, Jr.
General Electric Co., Pittsfield, Mass.

THE FOLLOWING investigation was made to study the effects of corona in producing voltage and current harmonics in transmission systems.

In the early work on corona in 1910 a very complete oscillographic study was made of voltage and current. It was found that the current wave of corona loss very much resembled the excitation current wave of a transformer or iron-core reactor. A typical corona wave is shown in Fig. 1.[1] This wave has a very prominent third harmonic.

In 1919 three-phase corona losses were measured up to about 220 kv. on a line approximately 100 miles long.[2] The corona losses, within the accuracy of such measurements, checked very well with the quadratic law. An interesting part of this investigation was the discovery of very large triple-frequency

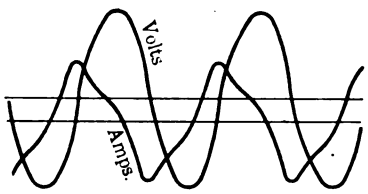

FIG. 1—CORONA CURRENT—SINGLE-PHASE

currents in the neutral of the grounded Δ Y transformers. This current was in every respect similar to the triple-frequency excitation current found in Y Y grounded neutral transformers. One explanation for its existence would be the amplification of slight residual triple-frequency excitation voltages in Δ Y transformers by the high capacity of the line. It seemed, however, as the result of the early work referred to above, that the harmonic was caused by corona loss over each half cycle.

When an alternating voltage higher than the critical corona voltage is applied to a conductor the loss starts at a given point during each half cycle as the voltage increases, continues over part of the half cycle, and finally ends at a given point as the voltage decreases. A varying amount of corona and loss thus occurs during a given part of each voltage wave. The conducting corona, in effect, makes a conductor which periodically varies in diameter. The capacity and loss, therefore, vary during parts of each wave. It follows that if a sine wave voltage high enough to cause corona loss is applied to conductors the current cannot follow a sine wave but must be distorted or contain harmonics. Fig. 1 shows that such a wave

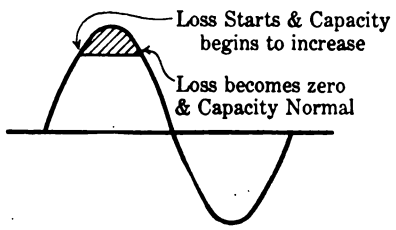

FIG. 2

contains a prominent third. The phenomenon is, in fact, very similar to that of distortion in the exciting current wave where distortion occurs chiefly due to changing permeability during each half cycle.

When corona loss occurs on three-phase lines with grounded neutral, three single-phase paths are afforded for the triple-frequency component of the current through the lines, the capacity to ground, the ground and the neutral ground connection as shown in Fig. 3.

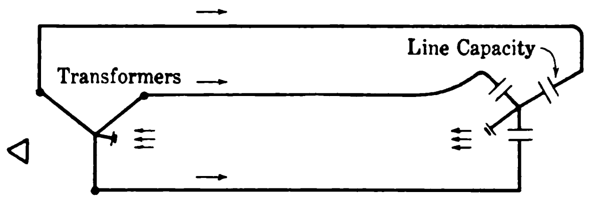

FIG. 3—THREE SINGLE-PHASE PATHS FOR CORONA TRIPLE-FREQUENCY CURRENT

If a transformer with a grounded neutral is used at the receiving end part of the current may also be supplied through the transformer. The triple-frequency currents cannot flow in the lines if the neutral is not grounded. This follows because the triple-frequency components are 3×120 deg. = 360 deg. apart or in phase. Fundamentally the sum of the currents flowing to the neutral point must be zero. Since the currents are in phase the triple component can satisfy

this condition only when it is zero; it can flow over the lines only when single-phase paths are afforded through the grounded neutral. Since with a sine wave voltage the corona current inherently contains a third harmonic the voltage between line and neutral must be distorted if this component is suppressed. Higher odd harmonics are also caused by corona. With symmetrically arranged conductors, however, only the third and odd multiples of the third can appear on the lines.

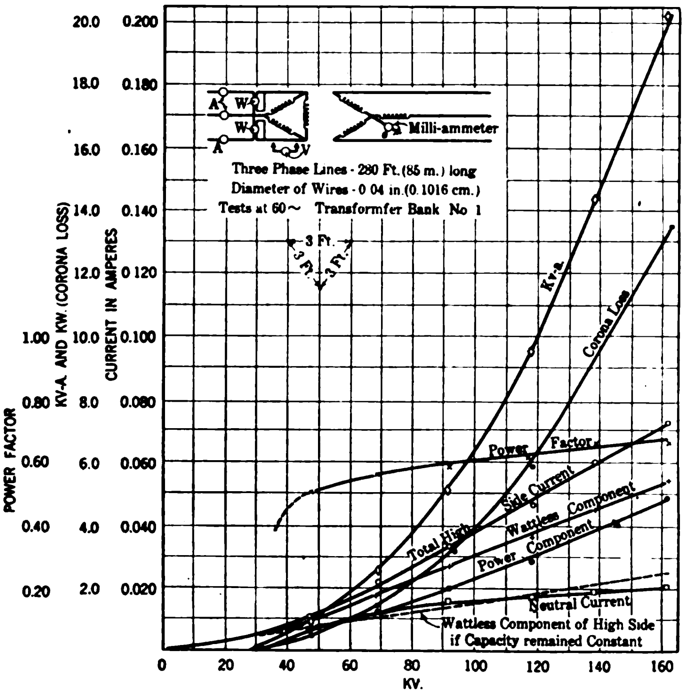

FIG. 4—CORONA CHARACTERISTICS OF A THREE-PHASE LINE WITH Δ Y GROUNDED NEUTRAL TRANSFORMERS

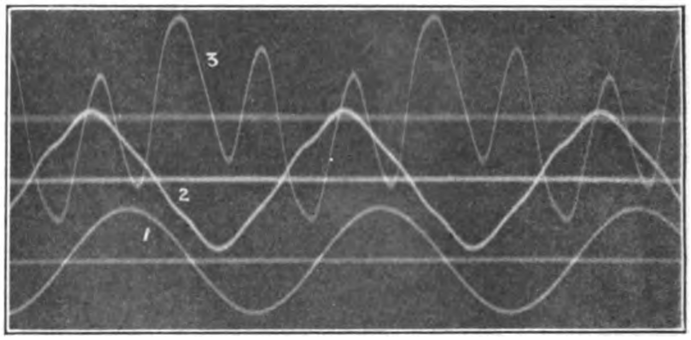
Tests were made on short three-phase lines of very fine wire so that the corona loss would be excessive and exaggerate conditions. The transformers were of such a size that the corona loss was an appreciable load. A sine wave voltage was used. There was a large triple-frequency current in the neutral.

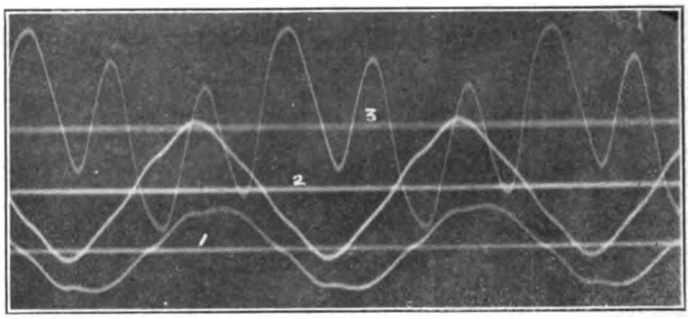
After curves were made on the line similar curves were made on Y-connected glass plate condensers of approximately the equivalent capacity of the line and of very small corona loss. The neutrals of the condensers and the transformers were connected together.

These tests were made to determine if the capacity of a line free from corona loss could cause high triple-frequency currents by amplification of residual triple-frequency magnetizing voltage harmonics in the Δ Y transformers. There were no appreciable neutral currents when the condensers were used.

Fig. 4 gives a set of curves showing the corona characteristics of a three-phase line with Δ Y-connected, grounded neutral transformers at the generating end and open-circuited at the receiving end. All of the measurements, with the exception of the line and neutral currents, were made on the low side but are corrected for losses and referred to the high side. The high side or capacity current starts at zero and increases in a straight line until the corona point is reached. The current then increases much more rapidly than the voltage. This increase in current is caused by a loss component and an added reactive component. The two components are plotted. It is seen that the apparent capacity of the line increases very rapidly with increasing voltage above the corona point. This is seen by referring to the dotted line which would represent the capacity current if there were no apparent increase owing to corona. To account for the reactive component it is necessary to assume that the apparent conductor diameter has increased from 0.102 cm. to 8.0 cm. or about 80 times at 150 kv. The neutral current starts at the beginning of corona loss and soon reaches a value which is comparable to the line current.



A—1. Low side voltage between lines.
2. High side line current.
3. Neutral current.



B—1. Low side line current.
2. High side line current.
3. Neutral current.

FIG. 5—ΔY TRANSFORMERS AND LINES—NO STEP-DOWN TRANSFORMERS

150 kv., 60 ~ applied to lines—Transformer Bank No. 1
(See Fig. 4)

Fig. 5 shows waves of low side voltage and line and neutral currents at 150 kv.

The generator voltage is a very good sine wave. The neutral current contains a very pronounced third harmonic superposed on residual fundamental. The fundamental component in the neutral is caused by lack of exact symmetry in the lines or transformers. Fig. 6 shows a similar set of curves taken at 32.4 kv.

The curves in Fig. 7 were made in the same way as those in Fig. 4 except that three banks of glass plate condensers connected in Y were substituted for the line. The condenser neutral was grounded and con-

(See Fig. 4)

nected to the transformer neutral. There was a slight corona loss on the condensers and leads. The neutral current is practically negligible. What there is, is probably due to the slight corona loss. Figs. 8 and 9 show the current waves at 110 and 150 kv.

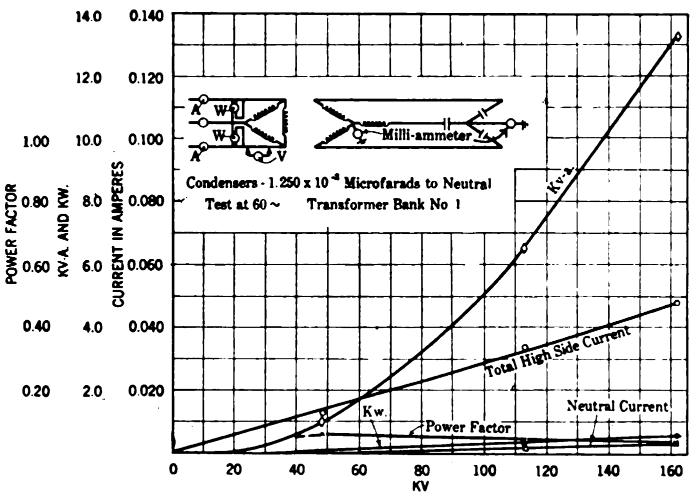

Fig. 7—Capacity Load on Δ *Y* Grounded Neutral Transformers

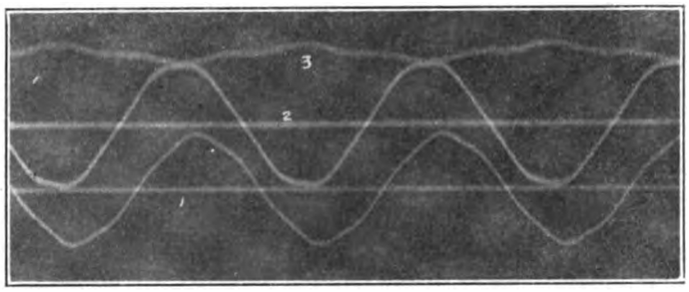
The neutral current wave at 150 kv. is interesting. It appears as a hump at the maximum of the voltage wave due to corona loss on the leads and edges of the plates. This loss does not appreciably change the capacity as in the case of corona on the wires.

Fig. 10 gives corona characteristics of a line with the transformers connected Δ Δ. The corona loss is not appreciably changed by suppression of the triple-frequency current.

A set of characteristic curves similar to those in Fig. 4 was made with a transformer of lower reactance. See Fig. 11. The general characteristics are very much the same. The neutral current is

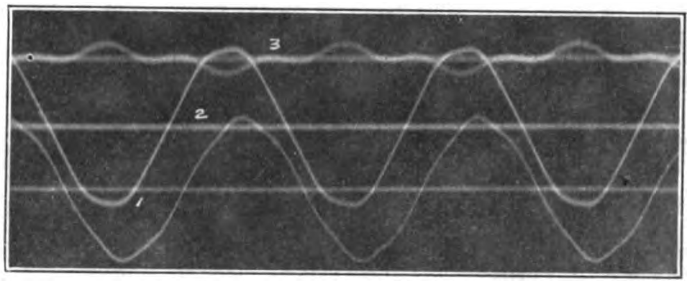


1. Low side line current.
2. High side line current.
3. Neutral current.

Fig. 8—Δ*Y* Transformers and Condensers in *Y*—Transformer and Condenser Neutrals Connected—No Lines

110 kv., 60 ~ applied to condensers.
Transformer Bank No. 1.
(See Fig. 7.)

less, however. The neutral current wave, as shown in Fig. 12, in addition to the third and fundamental contains a decided ninth. There is thus, apparently, a chance of amplification of the corona harmonics by the transformer reactance. The neutral current would, therefore, be expected to vary with the circuit constants.



1. Low side line current.
2. High side line current.
3. Neutral current.

Fig. 9—Δ *Y* Transformers and Condensers in *Y*—Transformer and Condenser Neutrals Connected—No Lines

150 kv., 60 ~ applied to condensers.
Transformer Bank No. 1.
(See Fig. 7.)

With a condenser load the currents were the same as in Fig. 7. The neutral current wave is shown in Fig. 13.

In Fig. 14 Δ *Y* grounded neutral transformers were placed on the step-down or receiving end. It will be noted that the greater part of the neutral current is supplied from the generator end. The waves are shown in Figs. 15 and 16. The neutral current of the receiving end contains a third and ninth. Fig. 17 gives the same wave with the load disconnected.

The measured and calculated corona loss curves, given in Fig. 18, check very well, especially when the small size of the wire is considered. The quadratic law used in making these calculations is given in the appendix.[3] This reduces to the form ordinarily used when the wires are large. While these measurements

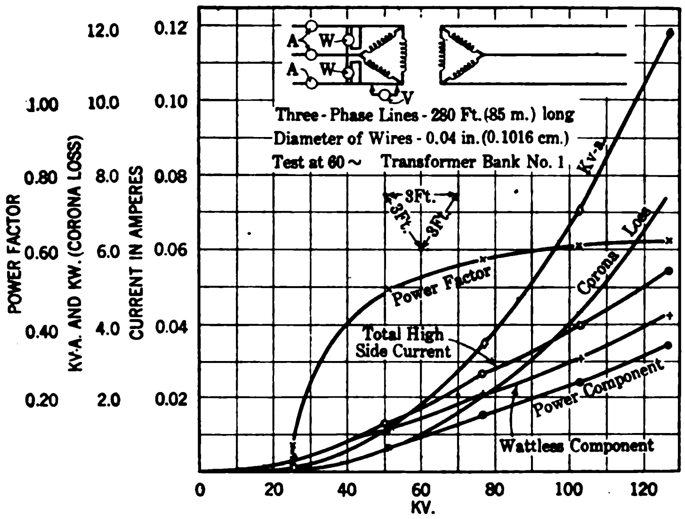


FIG. 10—CORONA CHARACTERISTICS OF A THREE-PHASE LINE WITH ΔΔ TRANSFORMERS

were made under conditions favorable for accuracy they emphasized the difficulty in obtaining accurate measurements on long three-phase lines. The deviation from the calculated curve is due to wave shape changes.

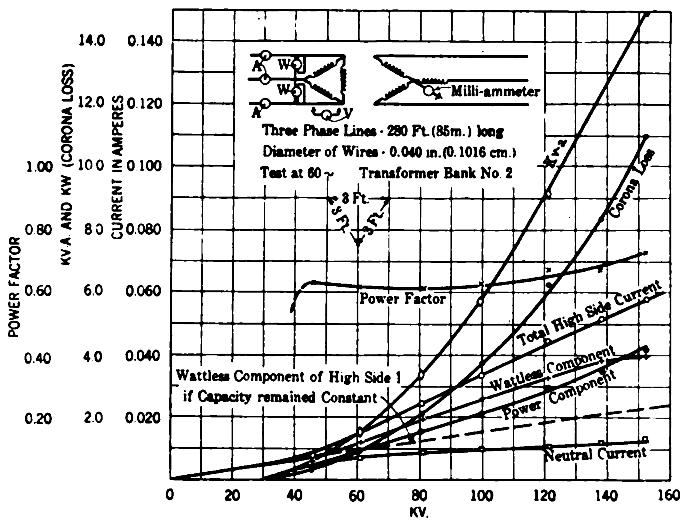

FIG. 11—CORONA CHARACTERISTICS OF A THREE-PHASE LINE WITH Δ Y GROUNDED NEUTRAL TRANSFORMERS

CONCLUSIONS

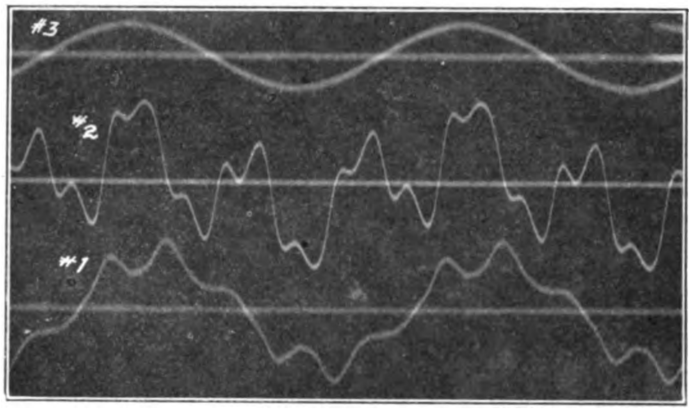
Corona will cause voltage and current harmonics, of which the third is the most prominent.

When Δ Y grounded neutral transformers are used, the third and odd multiples of the third harmonic, such as the ninth, may flow in the neutral.

The neutral corona current will not be greater for several grounds than for a single ground.

If the neutral is not grounded, distortion of the voltage may be expected.

The harmonic neutral currents may be of the order



1. Low side line current.
2. Neutral current.
3. Low side voltage.

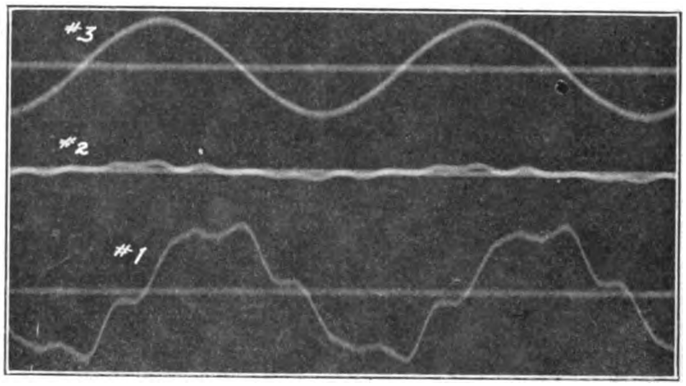
FIG. 12—Δ Y TRANSFORMERS AND LINES—NO STEP-DOWN TRANSFORMERS

100 kv., 60 ~ applied to lines.
Transformer Bank No. 2.
(See Fig. 11.)

of the capacity current of the line when the corona loss is excessive.

In properly designed practical transmission lines, the harmonic introduced by corona should be inappreciable.

The apparent capacity of the line increases rapidly



1. Low side line current.
2. Neutral current.
3. Low side voltage.

FIG. 13—Δ Y TRANSFORMERS AND CONDENSERS IN Y—TRANSFORMERS AND CONDENSER NEUTRALS CONNECTED—NO LINES

100 kv., 60 ~ applied to condensers.
Transformer Bank No. 2.

above the corona point. At 150 kv. the capacity current is equal to that for conductors of 80 times the radius of the one used.

The above tests were purposely made with very small wire and high voltage in order to exaggerate the effects of corona.

3. Peek, "Dielectric Phenomena in High-Voltage Engineering," page 136.

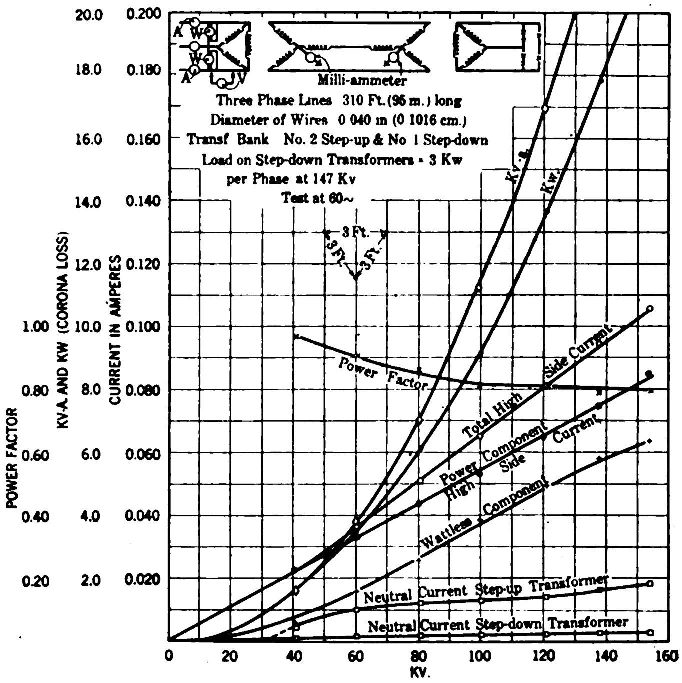


FIG. 14—CORONA CHARACTERISTICS OF A THREE-PHASE LINE WITH ΔY GROUNDED NEUTRAL TRANSFORMERS AT STEP-UP END AND $Y\Delta$ GROUNDED NEUTRAL TRANSFORMERS WITH LOAD AT STEP-DOWN END

APPENDIX

TRANSFORMERS

Bank No. 1

Each Transformer, 10 kv-a., 400/100,000 volts, 25 ~. Resistance low side, 0.08 ohms. Resistance high side, 15,400 ohms.

Reactance reduced to high side, 116,000 ohms at 60 ~

Bank No. 2.

Each Transformer, 10 kv-a., 440/100,000 volts, 60 ~.

Resistance low side, 0.042 ohms. Resistance high side, 5,760 ohms.

Reactance reduced to high side, 32,000 ohms.

Line

New copper wire. Diameter 0.040 inches (0.102 cm.). Wires arranged in a triangle at 3 ft. (91 cm.) spacing. Length of each wire 280 ft. (85 m.)

Condensers

Glass plates in air.

Capacity to neutral. $1.25 \times 10^{-3}\ \mu$ f.

Quadratic Law

$$p = 241\,(f + 25)\sqrt{\frac{r + 6/s + 0.04}{s}}\,(e - e_d)^2$$

10^{-5} kw. per km. per wire

$$g_d = g_0\,\delta\left[\left(1 + \frac{0.30}{\sqrt{\delta\, r}}\right) \times \frac{1}{(1 + 230\, r^2)}\right]$$

$e = m_0\, g_d\, r \log_e s/r$

s = spacing in cm.

r = radius in cm.

$m_0 = 0.95$

$\delta = \dfrac{3.92\, b}{273 + t}$ b = bar. pressure cm. t = temp. deg. cent.

$p = 0.00217\,(e - 14.)^2$ kw.

TELEGRAPHY AND TELEPHONY NOTES

M. A. Noss, heretofore engineer, has been appointed chief engineer of the Telepost Company, New York. In association with P. B. Delany, Mr. Noss is engaged in wire and radio communication research.

George H. Clark, engineer with the Radio Corporation of America, has gone to South America on a business trip.

Joseph W. Milnor, engineer with the Western Union Telegraph Company, is at work on an Institute paper dealing with the subject of "Ocean Cable Telegraphy" which it is expected will be ready for presentation next Fall.

The Standardization Committee of the Institute of Radio Engineers, composed of twenty-five prominent radio engineers, is at work on a complete revision of the definitions of the technical terms which have come into use in the radio art within the past few years. It is expected that the Committee's report will be ready for publication in book form by October or November this year.

In the lobby on the tenth floor at A. I. E. E. headquarters, New York, hangs a large size engraving of a painting showing S. F. B. Morse, inventor of the telegraph, exhibiting to a group of the leading scientists of his time the first model of the telegraph. The picture was donated to the Institute on June 27, 1912, by General Edward H. Ripley.

A master clock has been developed in Plainfield, N. J. by T. S. Casner and O. L. Badger, which is automatically corrected by the radio impulses sent out from Washington each day at noon. This clock can control a number of secondary clocks and a correction in time of the master clock by the radio signals corrects all of the secondary clocks which it controls. Heretofore the only method of automatic correction of clocks was by wire circuits to which all of the clocks to be corrected were connected.

Voltage and Power Factor Control of 66,000-Volt Transmission Lines Connecting Two Generating Stations

BY RAYMOND BAILEY

The Philadelphia Electric Company

The problem which confronted The Philadelphia Electric Company of providing for the control of voltage and power factor of the two 66,000-volt transmission lines connecting its Schuylkill and Chester generating stations is presented in this paper.

It is required that the control of voltage and power factor of the transmission lines referred to permit of the transfer of energy in either direction, at suitable power factor, up to the rated kv-a. capacity of the lines, with the generating stations operating at approximately equal bus voltages. The situation is considerably complicated by the necessity for supplying energy to several industrial substations, connected to these lines near the midpoint, which under certain operating conditions are supplied from one of the two lines.

Another important factor in the selection of regulating equipment is the severe short-circuit effects possible in a system of which the ultimate capacity of the present three generating stations will be approximately 500,000 kv-a.

The comparison made to determine upon the most satisfactory type of regulating equipment and the reasons for the selection of three-phase induction regulators are given. Data on the performance characteristics of the lines, with the induction regulators are included.

In the discussion of this problem of voltage and power factor control, certain conclusions of a more or less fundamental character are brought out.

THIS paper deals with a particular installation for control of voltage and power factor, made necessary by the interconnection of a large system, rather than a discussion of this question in a general way. An outline of this specific problem with its requirements, a discussion of the factors determining the selection of equipment, and a presentation and discussion of data on operating characteristics are included. This plan is adopted because it is thought that a paper of this sort will be of more value than one touching upon the subject in a more general way.

This interconnection is made by means of very short transmission lines and, therefore, does not involve any of the problems which go hand in hand with the use of long transmission lines, but is of particular interest on account of the exacting requirements for voltage and power factor control under various distributions of load, and the severe short-circuit effects encountered.

The Philadelphia Electric Company supplies Philadelphia, Pa., and surrounding territory with electrical energy mainly through three large steam generating tations, known as the Schuylkill, Delaware and Chester Stations, the present total capacity of which is approximately 275,000 kv-a. and the ultimate 500,000 kv-a. The growth of the demands for power in the district of which Chester, Pa., is a center necessitated the building of the Chester Station. With the completion about three years ago of this Station came the need for transmission lines connecting it with the Schuylkill Station in Philadelphia to permit of the most economical loading of these stations and make possible the use of minimum reserve generating capacity.

Two 66,000-volt lines, 14 miles long, of approximately 20,000 kv-a. capacity each, with step-up and step-down transformers arranged as shown in Fig. 1, are provided.

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

The transmission of 40,000 kv-a. for a distance of 14 miles would not in itself call for a line potential of 66,000 volts, but the possibility of future extension and interconnection with other systems made the use of a voltage as high as this desirable.

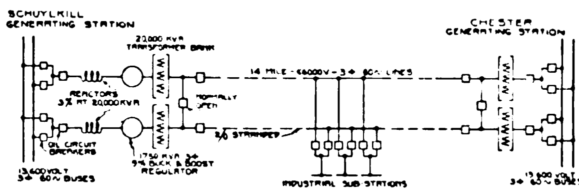

FIG. 1—SINGLE-LINE DIAGRAM OF SCHUYLKILL-CHESTER TRANSMISSION LINES

Disconnecting switches, instrument transformers, lightning arresters, etc. are omitted

The Delaware Station has direct cable ties with the Schuylkill Station, but has no tie lines connecting with the Chester Station.

THE NECESSITY FOR VOLTAGE AND POWER FACTOR CONTROL

The need for voltage and power factor regulating equipment on the Schuylkill-Chester lines is clearly

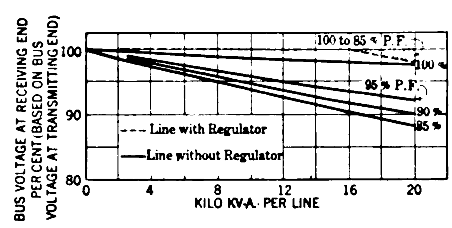

FIG. 2—CURVES SHOWING VARIATION, FOR SEVERAL DIFFERENT POWER FACTORS, OF VOLTAGE AT RECEIVING END OF LINE WITH THE KV-A. TRANSMITTED

brought out by the curves of Fig. 2, which show the inherent regulation of the lines, as shown by Fig. 1, except that the regulators are not included. It is obviously impossible to obtain satisfactory operation with the generating station bus voltage differing by

11.5 per cent, which is the figure for the transmission of 20,000 kv-a. per line at 85 per cent power factor. The curve for transmission at unity power factor indicates that 20,000 kv-a. can be transmitted over each line at that power factor with a voltage difference of only 2 per cent, which is entirely satisfactory. If this is done, however, there will be a certain amount of excess reactive kv-a. to be carried by the generating station to which the lines are supplying energy, as the power factor of the load is about 85 per cent; and this is, in some cases, impracticable to carry out, and uneconomical. This question of relative power factors of the various generating units will be discussed in detail in another part of this paper.

Regulation Requirements

An analysis of the problem brought out the following requirements for voltage and power factor control, which were important factors in determining the selection of equipment for this service.

The demand for large blocks of power, totaling about 15,000 kv-a. at about 90 per cent power factor, by three industrial consumers located adjacent to these lines necessitated their connection thereto. In order to meet all operating conditions, it was decided that regulating equipment must make possible the loading of both lines to rated capacity at either end, depending upon the direction of energy transfer, regardless of the size of the industrial load and whether it is split up between the two lines or all supplied from one line.

The vector diagram shown in Fig. 3 gives the voltage and current relations of these two lines under the assumed maximum load conditions given for point No. 2 of Fig. 9. Reference to this diagram will give an idea of the relative values of the impedance drops in the line supplying the industrial load and the line which runs straight through with no industrial load on it. To make such load conditions possible, it is evident that the two voltages e_t and e_u must be in series with the two lines in order to meet the bus voltage E_s, and the turbine governors adjusted for the desired kilowatt value. Further consideration of this question will show that as the industrial load diminishes or increases, or is split up between the two lines, the angle and magnitude of the two voltages e_t and e_u should change to keep the same power factor and voltage conditions. This would indicate that regulating equipment selected for this service should have to be of such character as to give a voltage of variable magnitude and phase angle.

The large ultimate generating capacity of the stations at each end of the lines will in the event of a short circuit at the bus deliver a maximum of 700,000 kv-a. The very high short-circuit effects encountered, combined with the necessity for the utmost reliability, led to a decision to install no regulating equipment but that of the most substantial and sturdy construction.

Comparison of Various Forms of Regulating Apparatus

Types of equipment considered for the installation in question include the synchronous condenser, the step-type regulator, the synchronous booster, and the three-phase induction regulator.

Synchronous condensers are not practicable for use in this instance because of the necessity for maintaining approximately equal bus voltages in both generating stations and for transmitting energy in both directions. The curves of Fig. 4 show clearly that at line power factors which give a voltage drop of permissible magnitude, the capacity of condensers required is excessive, resulting in a large investment and space requirement. As an example, if we assume the voltages at the ends of the lines differing by 2 per cent, it is found by referring to Fig. 4 that approximately 10,000 kv-a. condenser capacity is required at the ends of the line, thus necessitating a total capacity of 40,000 kv-a. The value of these condensers in reducing the amount of reactive kilovolt-amperes carried by the

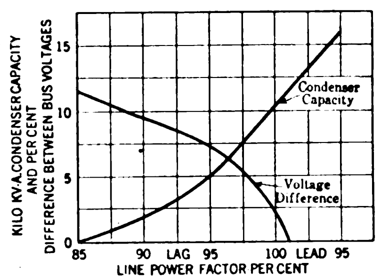

Fig. 4—Curves Showing Difference Between the Two Generating Station Bus Voltages When 20,000 Kv-a. is Transmitted Over the Lines at Various Power Factors, and the Condenser Capacity Required to Give These Power Factors When the Load Power Factor is 85 Per Cent

generators should not be overlooked, but in this instance it was not great enough to warrant their installation.

The step-type regulator which has been developed primarily for electric furnace and electrolytic work, consists essentially of a series transformer connected in the line and energized with voltages of various magnitudes from a special transformer supplied with taps and arranged with single-phase induction regulators, so that a gradual change in voltage is possible.

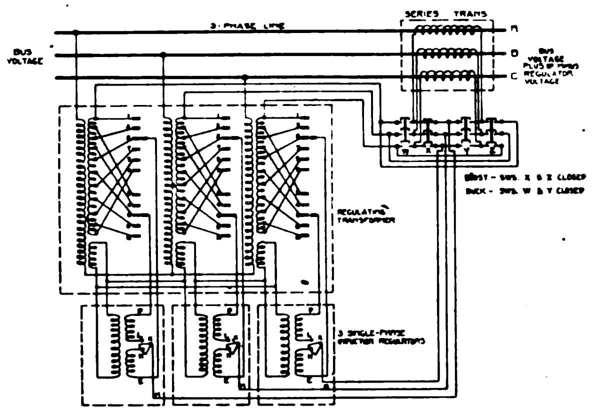

FIG. 5—DIAGRAM OF ELECTRICAL CONNECTIONS OF "STEP-TYPE" REGULATOR

Fig. 5 shows the elemental electrical connections of an equipment of this type for transmission lines regulation. The manner in which this apparatus functions is outlined in detail in Appendix A.

Among the advantages of this type of regulating equipment are that it can be built to withstand severe short circuits because the only apparatus in series in the lines are transformers, and it is slightly cheaper than other types of apparatus for the same service. The principal disadvantages are in the high-voltage sliding contacts which may give trouble and would be difficult to keep in condition, and the complication made necessary to secure the variable phase angle required to permit of loading the lines under different operating conditions.

The synchronous booster ordinarily does not give a variation of phase angle of its voltage; but it can be arranged so that the stator frame can be shifted at will through a certain angle, thus varying the phase angle of its voltage. When so equipped with a frame-shifting device, the synchronous booster gives more flexibility than the three-phase induction regulator because its voltage can be varied in both magnitude and phase angle, while that of the regulator can be varied in phase angle only.

In respect to this application, the induction regulator has many desirable features as compared with the synchronous condenser and the step-type regulator, and appeared to be superior to the synchronous booster. The problem, therefore, resolved itself to a great extent into an exact comparison of the induction regulator with the synchronous booster, equipped with a frame-shifting device. An analysis was therefore made of the operating characteristics of the transmission system which indicated that induction regulators giving a constant voltage of 9 per cent with a variable phase angle would permit of the desired conditions of load, and they were selected for this service in consideration of their advantages as compared with synchronous boosters, listed below:

1. More sturdy construction.
2. Ability to withstand greater short-circuit stresses.
3. Greater simplicity of operation.
4. Higher efficiency.
5. Smaller first cost.
6. Suitability for outdoor installation which greatly facilitated the arrangement of equipment.
7. Is not a "rotating" machine.
8. Less inspection and maintenance required.

It is true that the synchronous booster with a frame-shifting device permits of more exact control of the lines but the resulting gain is slight and is not comparable with the advantages of the induction regulator set forth above.

DESCRIPTION OF THE INDUCTION REGULATOR

Two 1750-kv-a., three-phase, 60-cycle, oil-insulated, water-cooled, motor-operated induction regulators of Westinghouse manufacture, designed to give 9 per

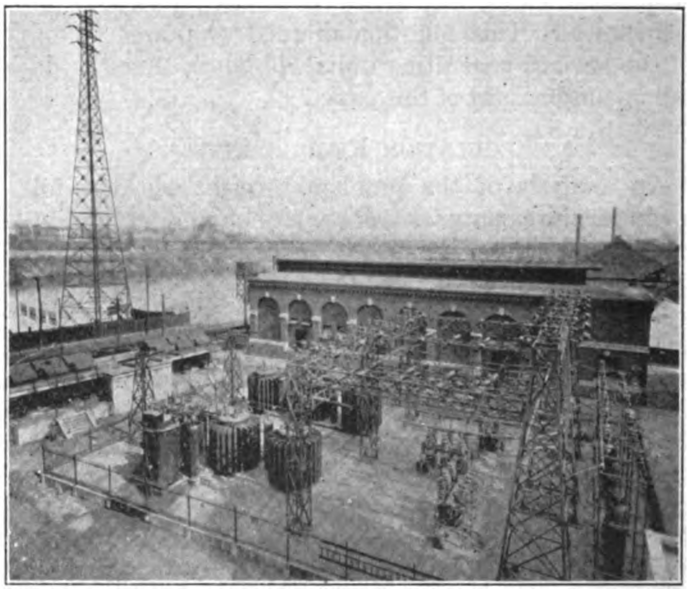

FIG. 6—GENERAL VIEW OF THE OUTDOOR SUBSTATION IN WHICH THE REGULATORS ARE INSTALLED

cent buck and boost on a 13,600-volt circuit, were installed in the Philadelphia outdoor substation, a general view of which is included in Fig. 6.

Fig. 7 is a close-up view of one of the regulators, showing breather and temperature indicating equipment. Arrangement for hand operation is provided but is not shown in the illustration. The height of

the regulator is 14 ft. 10 in.; the diameter 6 ft. 3 in., and the weight 56,000 lb. when filled with oil.

The regulators can easily be disconnected from the lines if desired when they are not "working" by unbolting the cable connection of each phase at the point *A* and reclamping at the point *B*, from which the cable for normal operation has been removed. This change in connection can be carried out in a very short length of time.

When operating at rated load, the losses of each regulator are 40 kw. and 20 gallons of cooling water per minute are required.

The stator and rotor coils are braced and insulated with A. I. E. E. class B insulation, in accordance with the standard turbo-generator practise.

The regulators are guaranteed to withstand successfully short-circuit currents as great as fifteen times the rated load value. Special stretch bolts are provided in the operating mechanism of the regulator so that in the event of an unusually severe short circuit, they will give way, thus preventing serious damage to the regulator.

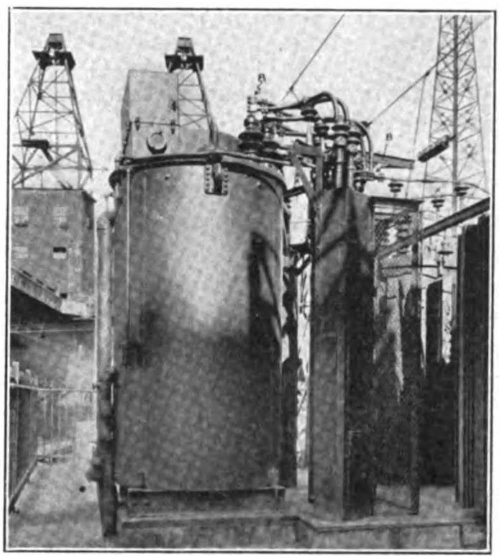

Fig. 7—Close-up View of One of the 1750-Kv-a. Induction Regulators

Reactors giving 3 per cent drop at rated circuit kilovolt-amperes are installed on the Schuylkill Station end of the line to limit short-circuit currents to a safe value in order to amply protect the equipment installed thereon.

The switches controlling the regulator operating motors are located on the generating station control panels for these lines, to facilitate operation.

To give further ease of operation, each regulator is provided with a position indicator located on the instrument panel of the line to indicate the angular position of the regulator voltage. This indicator consists essentially of a special 360 deg. power factor indicator; one set of potential coils is connected to the line potential transformers, and the other coil to a potential transformer connected across a secondary winding of the regulator. The regulator has four poles and the pointer of the indicator consequently makes two revolutions to one revolution of the regulator rotor. The markings of the dial of the instrument are shown by Fig. 8 and are arranged so that the operator can readily secure the desired load conditions. The pointer is usually in the half of the scale which has the words *to Chester* printed on it where transmitting energy to Chester, and is in the part of the scale marked *to Philadelphia* when transmitting in that direction.

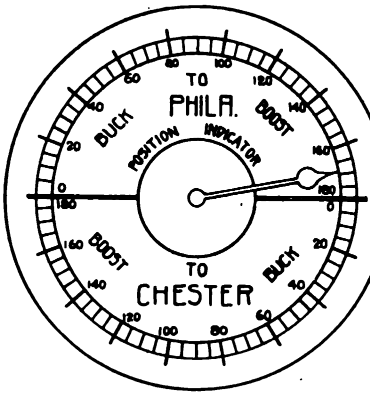

Fig. 8—Diagram Showing Marking of Position Indicator Dial

Discussion of Transmission Characteristics

The analysis of the operating performance of the transmission system was made by means of a circle diagram similar to the one shown in Fig. 9, developed to meet the need for some means for readily determining upon the load conditions which should be obtained on these lines under various operating conditions. The principles involved in the construction

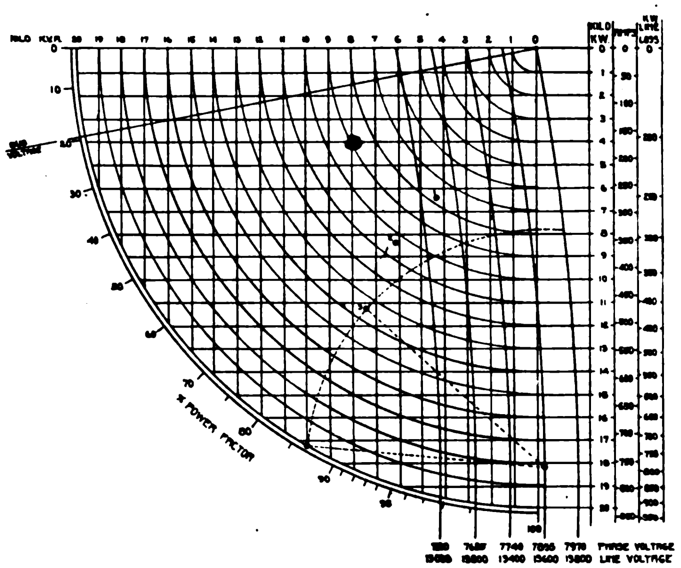

Fig. 9—Circle Diagram of Performance Characteristics of the Transmission Lines

of this diagram and the method of using it are outlined in Appendix B.

The curves given in Fig. 10 are plotted with readings taken from this diagram and show the transmission of energy from Chester to Philadelphia over the untapped line (no industrial consumers connected), for different amounts of kilovolt-amperes at 90 per cent power factor, furnished to the consumers from the tapped line which is supplied with 20,000 kv-a. at 85 per cent power factor at the Chester Station. Curves *A*, *B*, *C* and *D* show the kilovolt-amperes which can be transmitted at 85 per cent power factor (based on Chester bus voltage) over the untapped line with respectively, zero, one, two and three per cent, difference between the bus voltages of the Chester and Schuylkill generating stations, when the regulators are in one of two possible combinations of positions. Curves *A* and *B* do not extend to the 20,000 kv-a. point as do the others because it is impossible to obtain the load conditions necessary for this with zero and one per cent difference between bus voltages.

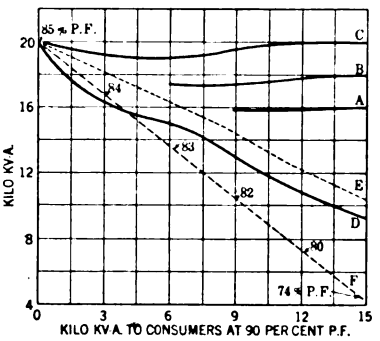

Fig. 10—Curves Showing the Amount of Kv-a. Which Can Be Transmitted From Chester to Philadelphia Under Various Conditions

Curve *F* (Fig. 10) shows the kilovolt-amperes transmitted over the tapped line through to the Schuylkill station and has marked along it at different points, the power factor at that particular load condition.

If the regulators are operated in the other possible combination of positions so that the line will receive kilovolt-amperes from the Chester Station at 85 per cent power factor, the kilovolt-amperes which can be transmitted with bus voltages equal or differing by as much as three per cent are shown by Curve *E*.

The second combination of regulator positions does not in most cases permit of as high kilovolt-ampere loads being carried as does the first and is, therefore, in general not desirable.

The two possible regulator positions referred to above are shown in Fig. 11 for an assumed load, of current I_l causing an impedance drop e_3. The regulator voltage can take either the position e_1 or e_2 to meet the receiving bus voltage E_1 provided the stations are not tied together through other lines. Figs. 10 and 12 indicate the desirability of one of these regulator positions as compared with the other.

It would appear as though regulator position e_1 is the better of the two, insofar as line power factor is concerned, because it apparently counteracts to a great extent the effect of the line reactance in producing reactive kilovolt-amperes which the generators must carry. This is not true, however, as the ratio current of the regulator when combined with the load current gives a total line current having an angle between it and the load current equal to the angular displacement of the line voltage caused by the regulator voltage, with the result that there is no change in line power

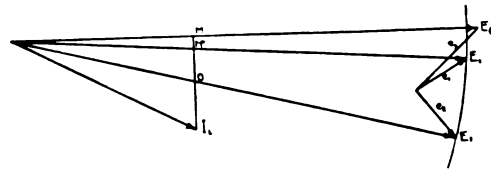

Fig. 11—Vector Diagram Showing the Two Possible Regulator Voltage Positions for an Assumed Load

factor made thereby. There is, of course, a small change of angle brought about by the exciting current and impedance of the regulator.

Fig. 12 shows the various kilovolt-ampere values that can be carried on the untapped line with the regulators in all the possible positions when the tapped line is carrying 20,000 kv-a. at 85 per cent power factor at the Chester Station and is supplying the industrial consumers with 15,000 kv-a. at 90 per cent power factor. Inspection of these curves will reveal the fact that with the one combination (Curve *B*) of regulator positions

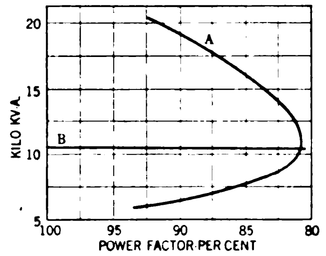

Fig. 12—Curves Showing the Various Load Conditions Possible on the Untapped Line When Transmitting from Chester to Philadelphia With Equal Generating Station Bus Voltages

it is practically impossible to vary the kilovolt-amperes, but the power factor can be varied. The other combination (Curve *A*) permits of considerable variation of both power factor and kilovolt-amperes and is the more desirable one.

Fig. 2 includes curves showing the transmission of kilovolt-amperes over the lines using the regulators, when there is no industrial load supplied from the mid-point of the line.

One of the limitations of the control of voltage and power factor is in the maximum voltage which can safely be impressed on the transformers at each end of the lines. Owing to the position of the regulators

relative to the transformers, this limitation is of consequence only when transmitting energy to Chester from Philadelphia.

Operating experience with these regulators for control of voltage and power factor has been very satisfactory and verifies the results of the analysis made to determine upon the capacity and characteristics of the regulating equipment. There are no rapid fluctuations of load on these lines under normal conditions and, therefore, no difficulty is experienced in maintaining the desired power factors. Some apprehension was felt at first as to the form of instructions which would enable the operators to readily load the lines as desired, but it was found that the position indicators used with the other instruments on the lines made satisfactory operation possible.

The lines connecting generating stations may be used under many conditions to increase the combined economy of these stations. The exact increase in economy made possible by securing more efficient loading of the generating units under various operating conditions is rather difficult to determine, as there are

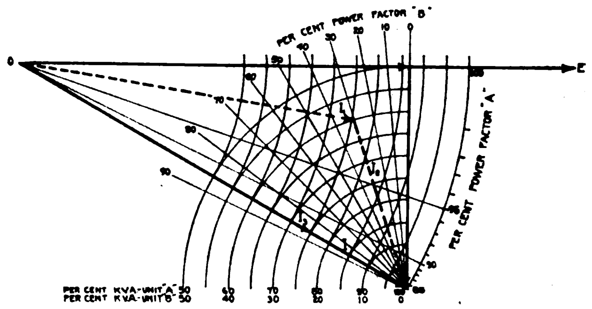

FIG. 13—GRAPHICAL REPRESENTATION OF THE INCREASE OF GENERATING CAPACITY REQUIRED BY OPERATION OF UNITS AT UNEQUAL POWER FACTORS

many factors involved. An instance where higher efficiency may be obtained is the case where the units of one station are lightly loaded and those of a second station heavily loaded, and by the use of the tie lines the load may be equalized so that all of the generators will operate at or near the most economical point, which in most cases is in the neighborhood of 75 per cent of the rated capacity. Or, again, we may have two stations in which the units are lightly loaded, in which case the proper transfer of load over the tie lines may make possible the shutting down of one machine and the operation of the remaining units in both stations at a higher efficiency. If, on the other hand, the generators in both stations are heavily loaded, an available spare machine could be started and the load equalized over the tie lines so that all of the machines would operate at a more efficient point.

In cases where there are generating units or stations differing by a considerable margin in economy, it is often found desirable to operate the efficient units at or near unity power factor, and carry the lagging reactive kilovolt-ampere on the less efficient machines. Where there is a large modern generating station with units of higher efficiency in it than in the older stations, it is customary to keep the most efficient station as near fully loaded as possible, at or near unity power factor. This arrangement requires, however, that the combined kilovolt-ampere generating capacity in use be greater than that of the load, the amount depending upon the difference in the power factors of the generators involved. This will be evident by referring to Fig. 13. To illustrate the point in mind, let us assume that an efficient station which will carry 75 per cent of the kilovolt-ampere load, is available. This station, which supplies the current I_3, will be called unit A and the scales so designated should be used to read its kilovolt-ampere and power factor. Scales marked unit B should be used in the same way for the less efficient unit. Reference to the diagram will show that when both stations are supplying current (I_3 and I) at the load power factor, the total kilovolt-ampere generating capacity is a minimum and is equal to 75 per cent (scale A) plus 25 per cent (scale B) or one hundred per cent of the load kilovolt-ampere.

If, however, unit A supplies the current I at approximately 99 per cent power factor, it will supply 75 per cent of the load kilovolt-amperes and unit B which supplies the current I_2 is operating at power factor of about 30 per cent and supplies kilovolt-amperes equal to 40 per cent of the load; the total kilovolt-ampere generating capacity under this condition is 115 per cent of the load kilovolt-amperes.

The excess kilovolt-amperes required increases as the power factor of unit A approaches unity, and that of the unit B approaches zero or vice versa, and reaches a maximum of 37 per cent at unity and zero power factor, respectively, with a load power factor of 85 per cent. When the load power factor is higher, this additional generating capacity required to operate at unequal generator power factors becomes smaller.

The discussion given above relative to operation of units to obtain maximum economy applies either to individual units in a station or to several stations of groups of generating units. It is obviously only directly concerned with the operation of tie lines when two or more stations are involved.

CONCLUSIONS

Interconnection of any particular system presents problems which must be solved individually by making a thorough analysis, including consideration of all pertinent features. The use of induction regulators for the control of voltage and power factor in the instance discussed in this paper does not indicate in general that this is the best method of handling the problem.

Summarizing, it could be said that equipment selected for the control of transmission lines should meet the following conditions which are more or less fundamental:

The equipment must permit of the desired transmission of energy at suitable power factor under all operating conditions.

Apparatus of sturdy construction which will give the greatest degree of reliability is absolutely essential, considering the great importance of this service. There is always a possibility that the breakdown of any equipment of generating station tie lines may cause disturbances throughout the system, which may lead to serious consequences. An installation which will require considerable inspection and maintenance is to be avoided.

Regulating equipment which does not permit of ease and simplicity of operation is, as a rule, undesirable. If the operation is complicated, errors are more likely to occur which sometimes lead to serious trouble.

The initial cost of regulating equipment and the cost of operation, including maintenance, are important factors and must be given due consideration.

It is hoped that this paper, although it is a discussion of a specific problem, brings out information of a general character which will be of value to those facing the problem of voltage and power factor control of interconnected systems.

The author wishes to express his appreciation of the helpful assistance of Mr. Frank R. Ford in the preparation of this paper.

APPENDIX A

The Step-Type Regulator

The manner in which the "step-type" regulator functions to give a gradual change of voltage can be most readily understood by following it through one step of the operation.

The voltage induced in each of the regulator coils *N-E* and *L-D* (Fig. 5) is equal to one-half of that between adjacent taps of the regulating transformer. If we assume switch *K* (Fig. 5) closed on contact *N* and the lead *E* of the regulator secondary coil connected to contact 5, then the voltage of the regulating transformer between leads 1 and 5 is impressed on the series transformer when the regulator is in the neutral position. As the regulator is turned in the direction so that the voltage of the coil *N-E* adds to the voltage between taps 1 and 5, the point is reached when the voltage impressed on the series transformer has been increased by the maximum regulator voltage, and the lead *M* is half-way between taps 5 and 6 in potential. As the voltages of coils *N-E* and *L-D* are exactly equal and opposite, the lead *L* is at the same potential as lead *M* and switch *K* is swung from contact *N* to *L*, the brush of lead *D* having just moved on to contact 6. This impresses the voltage from taps 1 and 6, minus that of the regulator winding *D-L*, on the series transformer, thus giving a voltage midway between taps 5 and 6. As the rotation of the regulator is continued, the voltage of the winding *D-L* decreases until the voltage of the regulator is zero and the impressed voltage is equal to that between taps 1 and 6. Further rotation increases the voltage of the induction regulator until the potential of lead *M* is half-way between taps 6 and 7, when the change is made to the regulator coil *N-E*, the selector switch having moved from tap 5 to tap 7 while the rotation of the regulator has taken place. The continuation of this process gives the desired change in voltage up to and including the capacity of the equipment.

The various switches and inductance regulators referred to above are mechanically interlocked so that they function in synchronism as desired. To change from buck to boost or vice versa it is necessary to operate the switches provided for that purpose and so designated on the diagram. It is possible to provide an equipment of this sort with switches so that the series tranformers can be short-circuited when they are neither bucking or boosting, so that they can be disconnected from the line even when it is carrying load.

APPENDIX B

Circle Diagram of the Transmission Lines

The construction of this circle diagram can be readily understood by referring to the vector diagram of Fig. 3, which shows voltage and current relations on the two 66,000-volt lines under certain assumed load conditions. The industrial load is assumed for the sake of simplicity to be grouped at the mid-point of the line. The following considerations refer to whichever line has no industrial load on it or, of course, to both lines if we assume no industrial load.

The length of the vector (Fig. 3) representing the impedance drop bears a definite relation at fixed bus voltage to the kilovolt-amperes transmitted over the line, and a scale placed on the diagram which will read the length of this vector *O-F* in any position can be marked to read kilovolt-amperes transmitted over the line.

A scale placed on the diagram so as to read the projection of the impedance vector on the line *O-D* can be marked to read kilowatts transmitted, and if desired, the reactive kilovolt-amperes can be read on the scale which indicates length of the projection of this same vector on a line 90 deg. from the one reading the kilowatts.

There is also a definite angular position of the impedance drop vector for each line power factor. At unity power factor it will take the position *O-D*; *O-B* is perpendicular to E_c and the ratio of *D-B* to *O-B* is equal to the ratio of the resistance of the line to its reactance. At zero power factor, the vector will swing around 90 deg. to the position *O-G*. The arc *D-F-G* can obviously be marked to read power factor of the line.

The circle diagram of Fig. 9 is based on the principles

outlined above, omitting most of the vectors of Fig. 3 for the sake of simplicity and adding the necessary scales each with a series of guide lines to facilitate reading the different values. In addition to the scales referred to above, there have been added, one for reading the amperes at 13,600 volts (as this was of more practical value than the amperes at 66,000 volts) and another for reading kilowatts lost in the transmission system. The kilowatt loss includes in addition to the copper loss in all parts of the circuit, the core losses of the regulator and transformers. These scales are based on a bus voltage of 13,800 volts and apply only to the line which is not carrying an industrial load.

It will be found that a circle, drawn on a piece of celluloid, representing the voltage of the regulator to scale, will be of material assistance in taking readings from the circle diagram. To take a set of readings, the celluloid is placed on the diagram so that some part of the circle coincides with the point which defines the end of the impedance drop vector on one line and the center of this same circle on the arc representing the bus voltage, which it is desired to have at the receiving end of the lines. The load conditions which it is impossible to obtain on the other line can be read at any point on the regulator circle, as desired.

In order to illustrate the method of using this diagram, two sets of readings of load on the untapped line will be taken for the load conditions shown by point No. 3 for the tapped line. If it is decided that the Schuylkill bus voltage should be 13,600 volts, then the regulator in the tapped line should be in the position indicated by the dotted line connecting with point 3. The point of intersection of this regulator voltage with the bus voltage line is the center of the regulator circle for the untapped line, and its position has been indicated on the diagram. The intersection of the regulator arc with the 20,000 kv-a. arc is the point for which readings will be taken to determine the conditions under which 20,000 kv-a. can be transmitted. The readings are: 17,200 kw. 87 per cent power factor, 10,000 reactive kv-a., 840 amperes, and 925 kw. loss. If it is desired to transmit energy from the Chester Station at 85 per cent power factor, the intersection of the regulator arc with a line from the center of the diagram to the 85 per cent power factor mark, is the point determining the readings, which are as follows: 18,000 kv-a., 15,200 kw., 9600 reactive kv-a., 750 amperes and 775 kw. loss. All readings obtained are based on a voltage of 13,800 volts at Chester, and if it is desired to operate this station at any other voltage the proper corrections must be made.

If it is desired to transmit energy over these lines from the Schuylkill Station to Chester, different points will have to be calculated and plotted on the diagram, as the impedance from the Schuylkill Station to the consumers is not the same as from the Chester Station to the consumers. If there is no load supplied to the consumers, the analysis of performance characteristics is somewhat simplified as the load condition which can be obtained on any line can be read without plotting points, by simply making use of the proper scales and the regulator circle.

It must be kept in mind that the values read from this diagram are approximate but are satisfactory for the purpose of making studies of line performance.

CITIZENS MILITARY TRAINING CAMPS

During the coming summer the War Department plans to hold within each Corps area a Citizen's Military Training Camp, to which all men between the ages of 16 and 35, of good intelligence character and physical condition may apply for admission. The camps are intended primarily for men of little or no military training in the hope that they will associate themselves with the National Guard or the Reserve. They will be maintained for a period of four weeks beginning not earlier than July 15th and not later than August 10th. The Government will pay for each man in training full expenses of transportation, subsistence, quarters, uniforms, equipment, laundry service, medical and dental care. The program of training calls for the initiation of young men into the conditions of camp life and the elementary duties of the soldier; stress will be laid on physical development through out-of-door games and sports; expert and individual medical attention will aim at the removal of minor bodily defects; social recreation will be afforded through all kinds of lectures, vaudeville, moving pictures, amateur and dramatic musical entertainment; on appropriate occasions voluntary religious exercises for men of all faiths.

The Military training Camps Association, 210 Mallers Bldg., Chicago, will send enrollment blanks to all applicants.

DEVELOPMENT IN NEW ZEALAND

There was an active interest taken in the development of hydroelectric sites by the New Zealand Government and individual companies, municipalities, and boroughs throughout the Dominion during 1920, with the result that plans were prepared for the development and distribution of a large amount of hydroelectric current for lighting and power purposes. The Government made good progress during the year in carrying out this general development scheme, covering both the North and South Islands. Government appropriations for hydroelectric development for the fiscal year ending with March 31, 1921, amounted to $3,224,055.

Modern Production of Suspension Insulators

BY EDWIN H. FRITZ

Ceramic Engineer, Pittsburgh High-Voltage Insulator Co.

AND

GEORGE I. GILCHREST

Westinghouse Electric & Mfg. Co.

This paper pictures the progress made during the past few years in the production of electrical porcelain. The information covers: First: The engineering and works organization. Second: The manufacture. Third: Design and test.

THE DEVELOPMENT of transmission line networks has progressed even more rapidly than most of the pioneers in transmission engineering anticipated. No doubt, the development has been materially affected by the increased cost of fuel, which has encouraged the engineers to develop available water power sites. Perhaps, one of the most influential factors has been the necessity of irrigating the fertile lands of the Pacific Coast States. Electricity from water power sources can be generated and transmitted to the farming districts and can be economically employed to pump water, to heat the houses, and to operate the household appliances.

The quality of electrical porcelain, although sufficient to properly insulate low-tension lines, proved entirely unsatisfactory when it became necessary to increase the transmission line voltages. The first thought of the engineer was to emphasize the mechanical strength, but in so doing, he sacrificed other characteristics. He believed the insulators should withstand handling, impact blows from rifle shooting, etc. He believed suspension insulators must be mechanically strong to prevent dropping the line in service.

There are numerous reasons why the quality of electrical porcelain did not keep pace with the progress in transmission engineering.

First: There were few transmission networks when electrical porcelain was first applied to high voltages.

Second: The demand for electrical porcelain was extremely variable. When a transmission project was under consideration, it was necessary to supply a large number of insulators in a short time. After the material for this project was manufactured and supplied, the manufacturer could not keep a continuous production of high-tension electrical porcelain in his factory. He must again manufacture low-voltage insulators and dry process material such as knobs, tubes, cleats, etc.

Third: The type of labor from which the manufacturer drew his supply had never been trained to appreciate the advantages that can be derived from labor saving devices. They had been very adverse to accepting any new type of machinery, perhaps, more so than the usual workmen.

The most regrettable and fundamental reason of the slow development of electrical porcelain has been the lack of cooperation between the ceramic and electrical engineers. The ceramic engineer was occupied with manufacturing problems only. The electrical engineer, on the other hand, was usually a consulting engineer because the transmission company itself could not afford to assign an electrical engineer to the application of electrical porcelain. The design recommended by him would incorporate his ideas and opinions. He would probably not consult with the ceramic engineer to determine the limitations in manufacture. The varied line of designs which every insulator company carried a few years ago is indicative of this condition.

Engineering Organization

The increased demand for electrical porcelain has enabled the manufacturer to command men of greater engineering ability. These men have sufficient training to appreciate the advantages that are gained by close contact between the manufacturer, the engineer, and the consumer. The organization of the modern electrical porcelain manufacturer is built on close cooperation between engineers who have supervision of the works and the application of the finished product.

The ceramic research laboratory operated as a separate department, is of vital importance. Its function is to investigate the present commercial raw materials; new sources of supply; the proportioning of ingredients; the glaze, etc. This laboratory has complete equipment, a portion of which constitutes a miniature clay working plant. This enables the engineer in charge of the laboratory to produce experimental bodies and determine such properties as dielectric strength, mechanical strength, both tensile and impact, resistance to temperature changes, firing range, and shrinkage. Fig. 1 will give a general idea of the completeness of this laboratory.

In connection with this, the proper selection of materials is of extreme importance. For example, we find different grades of clays in the same deposit, some of which will give considerably better results than others which may be only a few feet removed from them in the same strata. The ball clays which are now used contain a considerable amount of lignite and organic matter. This type of clay vitrifies at a much lower temperature than some of the cleaner ball clays and at the same time is a very tough and strong material, such as is necessary to overcome the severe stresses

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

which are encountered in manufacturing the complex insulator shapes. The low vitrification temperature is especially desirable because it assists the feldspar in the vitrification of the product and insures a greater firing range with less danger of underfired or overfired material.

English ball clay has always satisfied these characteristics in the past to the greatest possible extent. Laboratory investigations in recent years have discovered some promising American clays and at the present time experiments are being made on some clays in an undeveloped field in this country which seem to be even superior to the English clays. The laboratory is, therefore, continually investigating new materials and with the continual progress that has been made, it would not be too optimistic to predict that we may at some time find materials which will improve the present product.

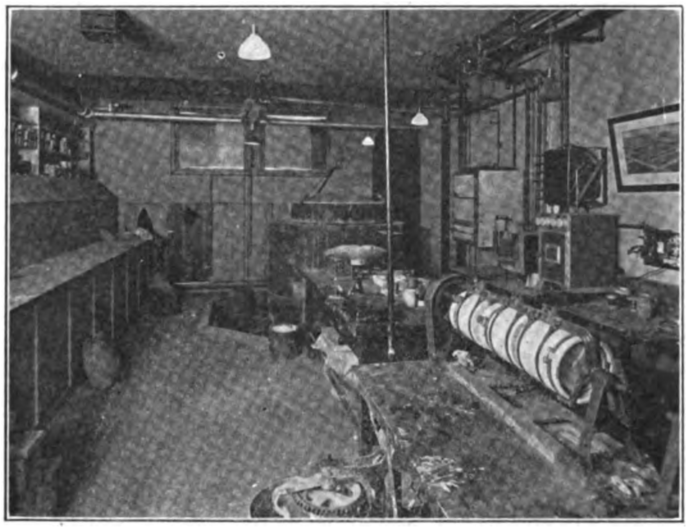

FIG. 1—CERAMIC RESEARCH LABORATORY—GENERAL VIEW

The proportioning of feldspar, flint and clay has been given very careful consideration in the research laboratories. The present commercial body is based on the results of this work. It is possible to obtain porcelain bodies from these materials in which certain characteristics predominate. However, since the application of electrical porcelain is very wide, it is necessary to sacrifice high mechanical strength or very high dielectric strength in order to obtain a body which will be satisfactory in all applications.[1]

A second ceramic laboratory is maintained at the works; the function of this department being to properly apply information obtained in the research laboratory to the commercial product and to see that all departments of the works function properly, *i. e.*, that the proportioning and mixing of the ingredients is uniformly performed; that the material is properly prepared for the manufacturing processes; that the speed of the machine in forming and trimm ng the ware is correct; that the firing conditions are uniform, etc. There is very close contact at all times between the two departments and by the continual exchange of ideas each is informed of the other's activities.

One of the most important activities of the works department is the testing of all raw materials as they are received, in order to insure uniformity of the material and the finished product. Feldspar has become so variable in recent years that the old method of assuming that the feldspar will always be uniform in quality is now a hazard. Each shipment must be tested especially in regard to fusibility, for it is this property which has become most variable. A sample is obtained from the car as soon as it is received; the flux value established and if not in accordance with purchasing specifications, it is rejected before coming in contact with any of the material in the bins. The remaining materials are tested in a similar manner. Other routine tests are the determination of the moisture content and non-clay substance in the clays from day to day so that this variable can be adjusted for on the scales and consequent uniform mixture produced.

The electrical engineering department functions in a similar manner. The consulting staff of the company is available when problems arise covering the design and application of the finished product. The Engineerign Department at the works supervise routine testing and the application to the product of suggestions that are made by the consulting staff. It is also a function of the Engineering Department at the works to give careful thought to any suggestions from the field which are based on the inherent design of the product.

MANUFACTURE

The modern electrical porcelain works are the result of the changed conditions and indicate what closer cooperation and a more scientific organization have accomplished. This is most forcibly illustrated in the slip house where the materials are mixed. This department was formerly found in the most dilapidated part of the works and gave an appearance which was repulsive to the intelligent class of workmen. In other words, it was located and operated under conditions which indicated that it was an unimportant department.

Today we find the reverse of these conditions. This department is now considered one of the most important if not the most important, part of the works and the general design and operating conditions are carried out accordingly. It contains the latest type of machinery, with special attention given to labor saving devices in order to make the processes more mechanical and eliminate the human factor wherever possible, with resultant greater uniformity. The department is well lighted and presents a sanitary appearance which is in keeping with the kind of work which is carried on.

The raw materials upon arrival after tests have been

1. "Experimental Investigation of Porcelain Mixes," G. I. Gilchrest and T. A. Klinefelter, *The Electric Journal*, March 1918, p. 77.

completed are unloaded in an efficient manner by means of suitable conveying equipment and stored in large bins to prevent contamination with undesirable substances which are carried about in the air in industrial centers. (Figs. 2 and 3.) These bins are directly adjacent to the mixing department and the same conveying equipment can be used to bring the material

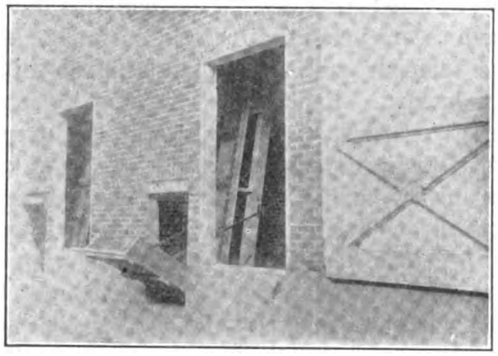

FIG. 2—EQUIPMENT TO HANDLE MATERIAL FROM CARS

into a location where it can be conveniently used in the process. (Fig. 4.) The materials are weighed with the minimum amount of manual labor and in such a way that the workmen cannot easily make an error of any consequence. The apparatus is built compactly so that the little transportation which is necessary is performed mechanically. (Figs. 5 and 6.)

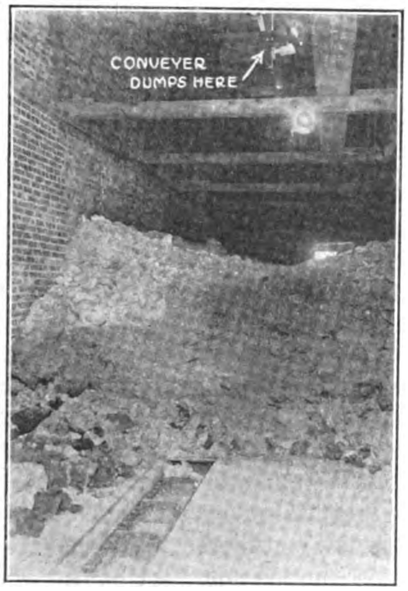

FIG. 3—MATERIAL STORAGE BIN

The feldspar and flint which were formerly mixed together with the clays in the blungers are now first ground in ball mills in the wet state sufficiently to produce a fineness which has been found to be necessary and which cannot be obtained in the dry state which is the means employed by the producers. (Fig. 7). The cost is large, but the resu ts that are obtained more than repay the manufacturer for this extra operation. The finer structure of the feldspar and flint gives a better mechanical mixture which makes these materials more active in their properties and effects a better performance of the body throughout the manufacturing process, especially in the firing operation. Vitrification begins at a lower temperature and a longer

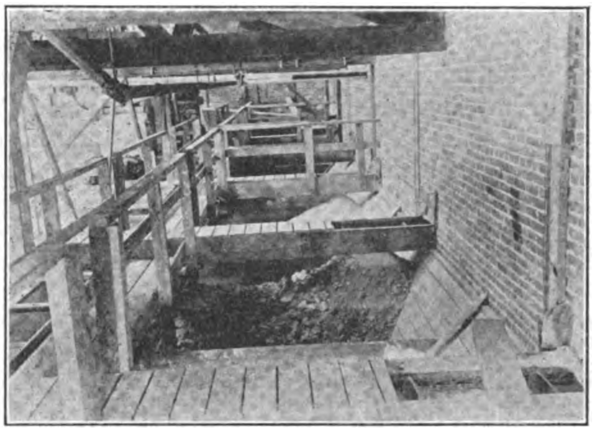

FIG. 4—MATERIAL BINS FOR DAILY CONSUMPTION

firing range is, therefore, obtained, or in other words, greater variation of temperature in the kilns is permissible without detrimental effect on the fired product. It is obvious that the danger of underfired ware is, therefore, materially lessened and on account of the improved methods of kiln firing, an underfired piece of electrical porcelain in the factory is indeed rare.

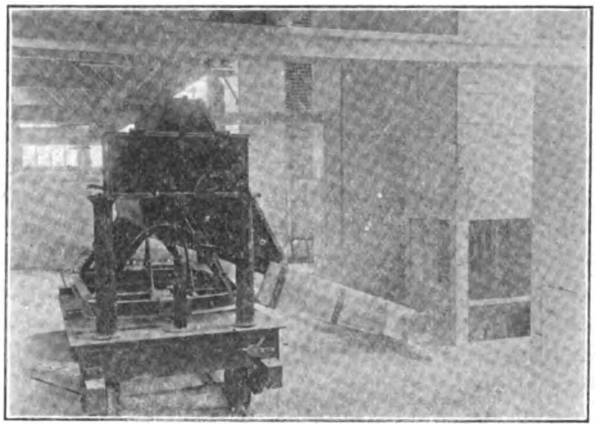

FIG. 5—METHOD OF TRANSPORTING MATERIAL TO MIXERS

Porcelain made from ball milled feldspar and flint is more homogeneous in structure and gives a very smooth fracture. It has a higher dielectric and mechanical strength, although in the case of the latter there is a limit to the fineness which will increase the value of this property. In general it has been very definitely proved that this operation is one of the greatest progressive steps in recent manufacturing developments.

While these materials are being milled the clays are mixed in blungers. The design of the blunger has been changed in recent years and machines are now on the market which are much more efficient and rapid in their performance. Complete slaking of the clays is assured in this type of mill, so that lumps of unmixed clay are not found in the blunger when it is discharged, with consequent variation of the mixture. This has been

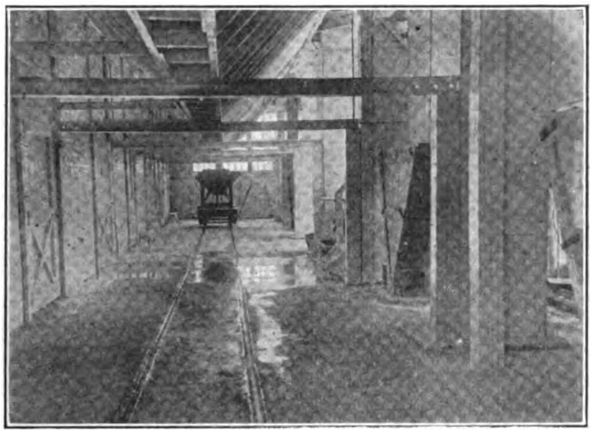

Fig. 6—Material Proportioning Equipment

accomplished by means of double rotating mixers which prevent any centrifugal force action and consequent collection of the particles at the edge of the tank which is so commonly found in the old type of blungers. Fig. 8). The feldspar and flint after being milled are added to this blunged clay slip and the entire mixture is then blunged sufficiently to produce as perfect a mechanical mixture as is possible.

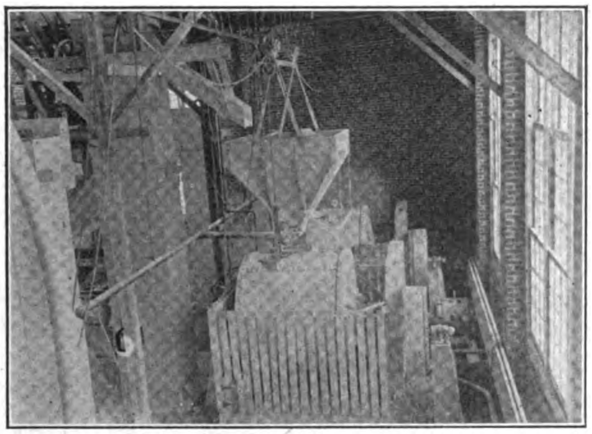

Fig. 7—General View of Ball Mills

The amount of water which is added to the clay flint and feldspar in the blungers and ball mills is carefully controlled by means of self-regulating water tanks above these machines. The amount of water in each tank is set from day to day in order to make proper adjustment of the water contained in the materials themselves. At the same time the water is heated to the proper temperature and kept constant by means of automatic temperature regulators. In this way the liquid in the ball mills and the blungers is always of the same density and temperature which is essential in pumping uniform filter cakes and in keeping the plastic clay body at the proper temperature. (Fig. 9).

The clay slip is passed over a double set of lawns, the first lawn being of a coarser mesh than the second.

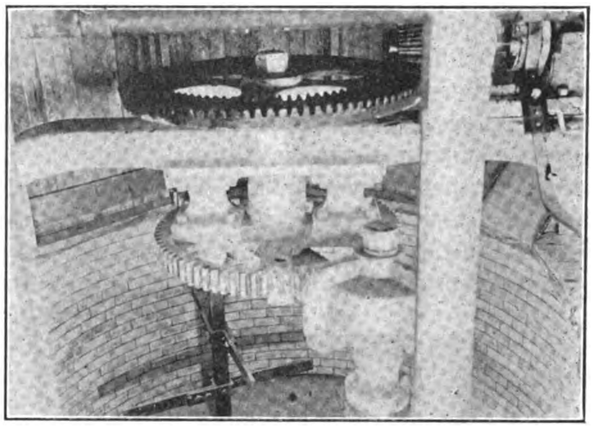

Fig. 8—View of Blunger Detail

This distributes the amount of residue on each lawn and lessens the danger of breaking the lawn and consequent passing through of coarse materials. After screening, the material accumulates in cisterns, which are now built of considerable size and number. The object in view is to provide storage for the clay slip after it has completely passed through the mixing

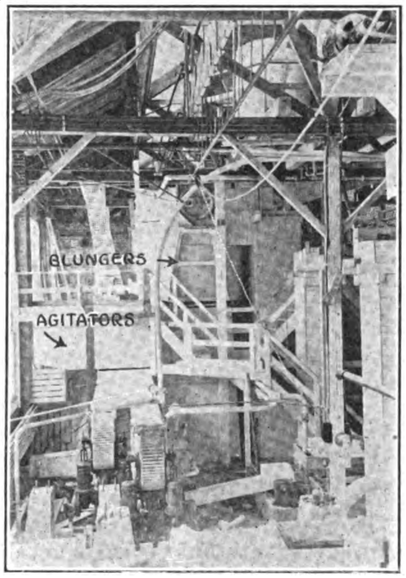

Fig. 9—General View of Section of Slip House

process where the air which is contained can be eliminated, giving a more homogeneous clay slip.

The pumps which force the material from the cisterns to the filter presses are designed to preserve the uniformity of the clay slip. The pumping action of the piston is now transmitted upon a diaphragm in order to isolate the clay slip from the pumping action.

Mixing of air in the slip at this point is, therefore, impossible and at the same time it does not get in contact with the oil in the cylinders. If the air is removed in the cisterns the filter cakes which will be produced at the press will be solid and contain no blebs of any kind. Furthermore, the pumps will not produce a higher pressure than what they are set for, so that the filter cakes are always uniform in water content and working qualities.

With such filter cakes the beneficial effect of aging is largely reduced and it has actually come to a point where equal results can be obtained from the manufacture of insulators from clay directly from the filter presses. Furthermore, ball clays have already passed through considerable natural aging and weathering conditions, and since they compose the major part of the clay content, the body is not noticeably improved

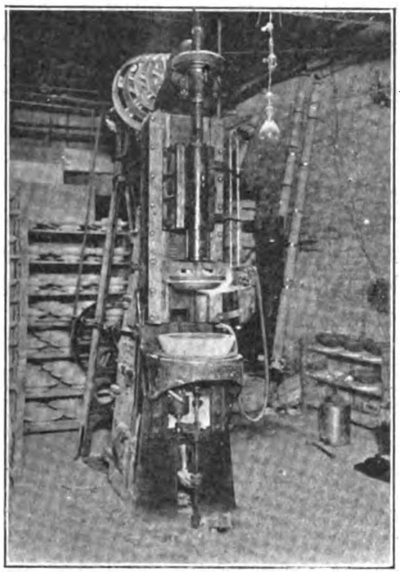

Fig. 10—Forming Machine

by a small amount of artificial aging. For this reason, aging would have to extend over a period of at least one month before any noticeable results would be obtained in the product and this, of course, necessitates a storage capacity which is not commercial in this country.

In pugmilling the material in preparation for the moulding process, the more modern and scientific methods of mixing have overcome many of the troubles which formerly were traced to the pugmill. It is now much simpler to produce a satisfactory material from the pugmill and with the improvements in this machine which have been obtained, the ever-present trouble with laminations has been largely overcome. If the material leaves the pugmill free of laminations and with no air contained, the success of the moulding of the insulators is practically assured.

In forming the insulators machine operations are used entirely. This method has proved to be superior to the jiggering process, because of the greater pressure which is obtainable and the elimination of the human factor with the consequent possibility of a non-uniform product. A greater production can be obtained from the machines with an improvement in quality. (Fig. 10.)

By means of modern conditioning dryers, the insulators can be rapidly and uniformly dried to the stage where they can be removed from the moulds without distortion. (Fig. 11.) They are then ready

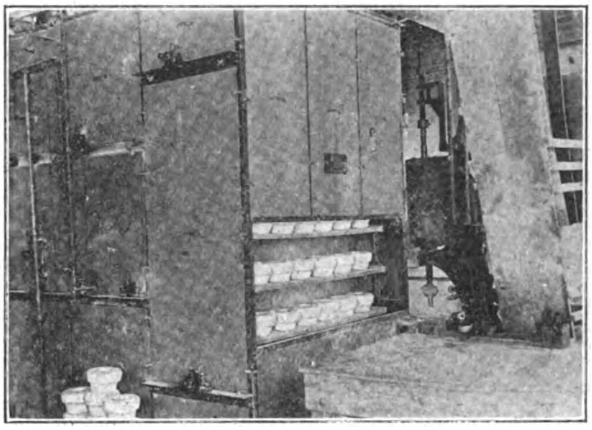

Fig. 11—Conditioning Dryer

for trimming which perfects the insulators into their final form. In drying the product to the bone-dry stage the modern tunnel dryer has given the manufacturer a means of drying under carefully controlled conditions as to temperature and humidity. This is of primary importance in drying the material with the minimum amount of strain and at the same time provides a method which is labor saving. A truck carries the insulators through the dryers and they are then taken directly to the glazing department where the glaze and sand coatings are applied.

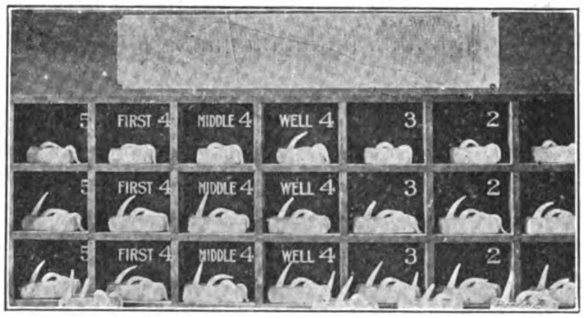

Fig. 12—Typical Photographic Record of Kiln Firing

The color of the glaze has proved of some assistance in indicating the degree of heat treatment received in the kilns. This method, however, has its limitations and is not completely satisfactory.

Recent experimental work in the laboratory has shown that there is a possibility of having the glaze indicate firing treatment by means of its luster. If this glaze can be made satisfactory to the trade, there is no doubt that it will provide a very accurate means of

determining the degree of heat the insulator has received in the kiln.

In firing the material, various steps are taken to insure a uniform product such as the location of numerous cone plaques in all parts of the kilns and the use of the electric pyrometer with recording chart which is operated according to a standard firing curve in order to standardize the entire firing cycle. The cone plaques are marked according to their position in the kiln, so that upon removal if any show that insufficient heat has been received, the insulators which are immediately adjacent to such a cone plaque can be segregated and refired. At the same time all of the cone plaques from one kiln are gathered together and assembled in a rack which is photographed together with the pyrometer chart for the kiln. This gives a complete and permanent record of the firing of each kiln and also determines the efficiency of each kiln and of the kiln firemen. (Fig. 12.)

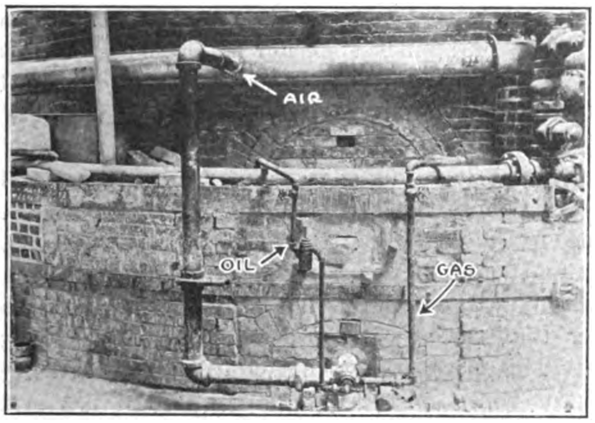

FIG. 13—COMBINATION OIL AND GAS BURNER

Natural gas, coal and more recently oil are used as fuels. Natural gas is undoubtedly the most desirable fuel because of the ease of control and comparatively low temperatures in the fire boxes. The works are located in the natural gas fields where the supply is abundant. However, protective measures by the gas producers have limited the supply during very severe weather. It, therefore, became necessary to resort to other fuels which has brought about the use of oil. This fuel has proved to be much more satisfactory than coal, because its control can be as easily manipulated as that of gas and the only difficulty encountered is the excessive local heat of the oil flame. This has been overcome by the use of superior refractories so that equal results can be obtained with oil, the only difference being in the cost. Coal is, of course, cheaper than oil as far as cost of fuel itself is concerned, but the ease of control and the more uniform and satisfactory results which are obtained from the oil with consequent better quality of finished product has proved conclusively that the final cost of production with oil is cheaper than coal. Combination oil and gas burners are used so that gas can be used whenever available and the change to oil can be made at any time without loss of heat in the kiln. (Fig. 13.)

ROUTINE TESTING

The porcelain parts are carefully inspected as they are drawn from the kilns. Parts having cracks or other defects that can be detected visually are immediately scrapped. Thereafter the parts are subjected to a 60-cycle flash-over test. The characteristics of the transformer are such as to give a 60-cycle voltage with a superimposed high-frequency voltage. Fig. 14 is indicative of the test.

The insulators having cemented hardware are then assembled with neat Portland cement and placed in a closed chamber where they are subjected to an atmosphere of steam during the initial set of the cement. The insulators are then given a routine mechanical test at a load dependent upon the inherent design of the insulator and its application. After the routine mechanical test the assembled insulators are again subjected to a flash-over test, similar in characteristics to that applied to the porcelain parts. It is not necessary, of course, to give the suspension insulators not assembled with hardware a second electrical test.

DESIGN TESTS

It is very difficult to provide tests which will duplicate service conditions since it is impossible to reproduce in short periods of time in the laboratory the temperature cyclic changes which will occur in line service. Although engineers who are familiar with the testing of electrical porcelain do not feel satisfied with laboratory tests, nevertheless all agree that the design which passes severe laboratory tests has apparent merits.

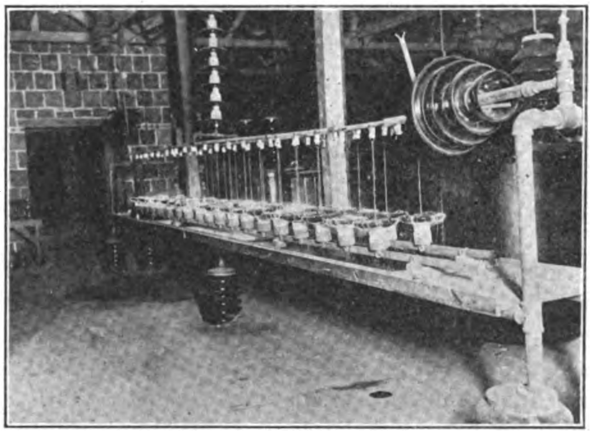

FIG. 14—ROUTINE ELECTRICAL TEST OF PORCELAIN PARTS

Many articles have been published in the engineering periodicals during the last few years discussing types and causes of failures of electrical porcelain. These articles have been presented by men in the field and by representatives of the manufacturers. In general, engineers agree that the failure of suspension insulators having cemented hardware is largely due to

two causes. First: Porosity. Second: Mechanical stresses.

No doubt, porosity was one of the vital factors in causing the failure of the suspension insulators manufactured prior to about 1914. It is not necessary to go into a discussion of the causes of porosity. A brief statement that the porous insulator is an insulator that is underfired is perhaps sufficient. Of course, if we consider the problems of the manufacturer it may be that the material is not properly fired, that the ingredients are not properly proportioned or ground, etc. The subject of porosity affords sufficient information for an article. Now that due consideration is given to all of these factors, the more progressive manufacturers have practically eliminated porous ware.

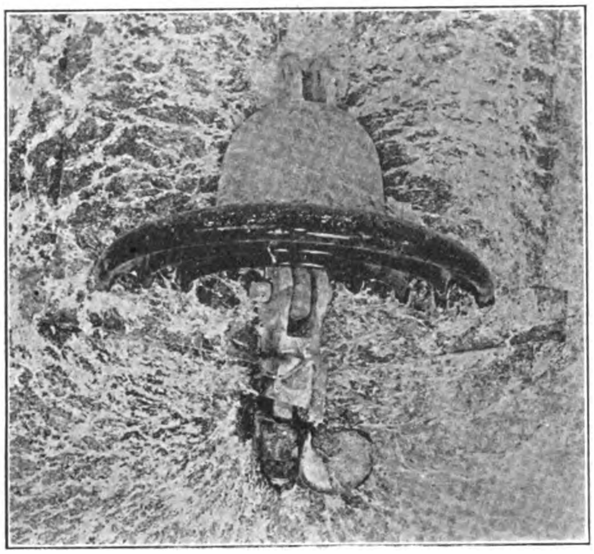

FIG. 15—DIELECTRIC FIELD OF CAP AND PIN SUSPENSION INSULATOR

Second: Mechanical stresses have always been instrumental in the failure of suspension insulators having cemented hardware. Although porosity may have been a vital factor prior to about 1914, mechanical stresses have continued to give trouble and are more difficult to eliminate. The subject of mechanical stress has also been very generally discussed in the engineering periodicals and everyone is familiar with the present assembly methods and the very gratifying results obtained. The elimination of the mechanical stresses caused by temperature changes without doubt, depends upon first, the design; second, the assembly of the hardware and porcelain; third, the setting of the cement under temperature and moisture conditions, etc.

It is impossible to give in any detail an analysis of the design tests which our engineers have made during the past few months. In order to give a general picture of the problems involved, the various lines of research are indicated by the following paragraphs.

ELECTROSTATIC FIELD

The cap and pin suspension insulator or the interlinked type insulator do not represent ideal electrical designs from a consideration of the electrostatic field. However, it is necessary in nearly all commercial designs to sacrifice some efficiency of electrical design to produce a commercial unit which will be economical under the average conditions, *i. e.*, a unit which will perform satisfactorily in dry climates, or in humid climates, indoors, outdoors, etc. The design of insulators based on theoretical principles is discussed in considerable detail in a paper presented before the American Institute in June 1918.[2] It is not necessary to go into a detailed discussion of the electrostatic design of suspension insulators since everyone is somewhat familiar with the theoretical principles.

For general information and interest, Figs. 15 and 16 are included. Fig. 15 pictures the electrostatic field of the cap and pin suspension insulator; Fig. 16 pictures that of the interlinked insulator. To obtain the most efficient electrical characteristics the lines of of force in the area about the insulator should be either parallel or perpendicular to the surface of the insulating material. It is interesting to note the difference in the field about the two suspension insulators. As a matter of fact, the distribution of the stress in the air about the interlinked type insulator is materially better than the distribution about the cap and pin type. This perhaps, explains why the interlinked type insulator has a flash-over comparable to that of the cap and pin type, although there is more corona formation around the interlinking hardware of the interlinked insulator below flash-over than about the cap and pin. It is probable, however, that the corona formation does not build up as rapidly over the surface of the insulator sheds as in the case of the cap and pin because of the more favorable electrostatic field.

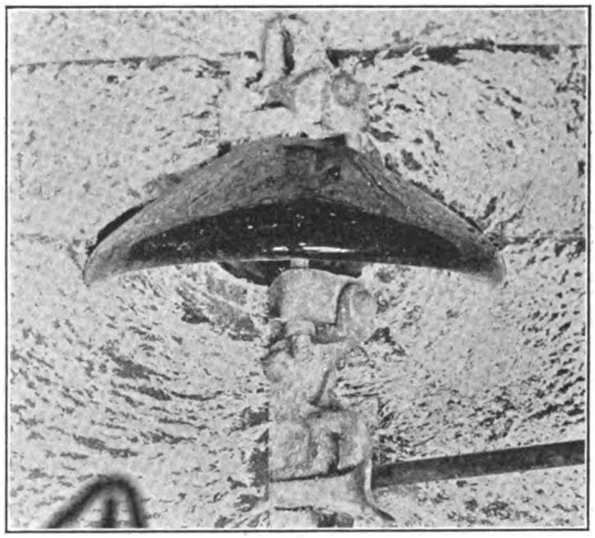

FIG. 16—DIELECTRIC FIELD OF INTERLINKED INSULATOR

Several authors have discussed the advisability of

2. *Application of Theory and Practise to the Design of Transmission Line Insulators*, G. I. Gilchrest, TRANS. A. I. E. E., 1918.

obtaining an insulating material having a low dielectric constant or a high dielectric constant. Obviously it is possible to divert further from the theoretical principles in the design of the insulator if the material has a dielectric constant approaching that of air. Electrical porcelain has a dielectric constant of approximately five compared to the dielectric constant of one of air. It is impossible to vary this constant to any great extent by changing the composition of electrical porcelain.

To the practical engineer it may appear that investigations of the field form of insulators are of no particular consequence. However, the determination of field form of a separate unit or assembled units is particularly useful in determining the concentration of stress. Although experimental methods indicated in the figures do not give the distribution of stress, nevertheless when obtaining the results the investigator can determine the sections of high local stress by the manner in which the particles of material act during the experiment. This method of investigation is applicable to strings of units as well as to separate units.

Mechanical Stress

It is, perhaps, more difficult to provide tests to indicate the comparative resistance of insulators to temperature changes. We have followed a number of lines of investigation and will very briefly discuss each line.

Special Design of Eyebolt

A theoretical analysis of the mechanical stress transmitted to the porcelain by the cemented hardware indicates clearly that the expansion of the eyebolt is probably the most serious factor. To definitely determine this in the laboratory, porcelains assembled with caps alone, with eyebolts alone, and without hardware, were tested by alternate immersions in hot and cold water baths. The porcelain parts assembled with eyebolts alone failed under the same severity of tests as the assembled insulators. The porcelain parts without hardware and with caps alone did not fail under any of the temperature change tests.

Several modifications of the solid eyebolt were then considered and two special types were produced and tested. These were assembled with identical porcelain parts and metal caps and under the same conditions. The two modifications consisted of (A) an eyebolt having two drop forgings assembled with a porcelain sleeve. (B) eyebolt having a one-piece drop forging with a metal sleeve into which the eyebolt could be turned.

These two special designs were compared directly with standard design having the solid eyebolt. The insulators were tested by immersing them alternately in water baths maintained at zero and 100 degrees centigrade. The periods of immersion were varied from one minute at the start to ten minutes at the end. The insulators were not under mechanical load during the tests. Briefly the results of this were as in Table I.

TABLE 1

	Number of Failures under Test								Passing all Tests
	1	2	3	4	5	6	7	8	
Solid Eyebolt	1			4	5		2	2	2
Eyebolt with porcelain sleeve						1	2	6	5
Eyebolt with metal sleeve									14

From an analysis of this table it is very apparent that the insulators having a separable metal sleeve resisted the mechanical stresses from temperature changes more successfully than the insulators having the solid eyebolt or the eyebolt with the porcelain sleeve. Also the insulators having the eyebolt with a porcelain sleeve resisted the mechanical stress better than the insulators with the solid eyebolt.

The inherent design of these insulators is such that the ultimate strength and the combined mechanical and electrical strength are practically identical. Under combined electrical and mechanical test the type with the solid eyebolt gave the highest results averaging between 10,000 and 11,000 pounds. The insulator with the eyebolt having the porcelain sleeve averaged between 9,000 and 10,000 pounds the insulator having the separable metal sleeve averaged between 8000 and 10,000 pounds. The lower strength of the two special types was due largely to the lower strength of the eyebolts. Later, additional samples were made which gave practically the same combined mechanical and electrical test as the solid eyebolt type.

After making these preliminary tests with insulators not subjected to mechanical load, it was thought particularly desirable to have similar tests made with the insulators under tension. The three designs were again tested under a series of temperature changes at 4000 and 5000 pounds load. During the immersions, the insulators were assembled in strings in series with a dynamometer as indicated in Fig. 17.

The load on the insulators shifted somewhat during the transfer from the hot water bath to the cold water. This amount of change varied for the different units and is, perhaps, somewhat indicative of the rigidity of the assembly. It is obvious that the insulator showing the least change of load must have the greatest resilience in its assembly.

	Load Shift under		Per cent Loss	Combined Electrical and Mechanical Strength
	4000 lb.	5000 lb.		
Solid Eyebold (corrugated)	700	625	50	11,350
Solid Eyebolt (sanded)	425	375	40	11,640
Metal Sleeve	750	500	20	11,090
Porcelain Sleeve	825	525	30	10,760

All of the failures occurred during the test under 5000 pounds load. In these tests the insulator having the eyebolt with a metal thimble again proved superior. A portion of the porcelain parts assembled with the solid eyebolt had corrugated gripping surfaces and a portion sanded surfaces. The insulators with the sanded surfaces proved superior in resisting temperature changes and gave less change in load during test, indicating that the sanded surface affords greater resilience than the corrugated surface.

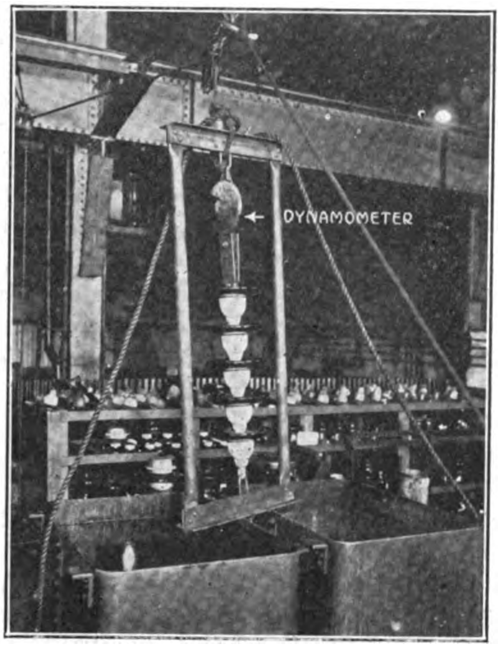

Fig. 17—Testing Insulators by Temperature Changes

Although the insulators with the special design of eyebolt proved superior to the type with the solid eyebolt, it is not possible to determine in the laboratory whether or not service results will be particularly better. We have, however, sufficient of each type now in transmission line service to determine, we believe, in the next two or three years, whether or not there is any advantage in these modifications. However, the improvements in design and assembly have resulted in insulators of solid eyebolt type, that will undergo these laboratory tests without failure.

Special Cement

A number of investigators have contended that Portland cement may be the cause of some of the line failures. They contend that the cement gradually crystallizes and that it may transmit mechanical stresses to the porcelain. Moreover, the coefficient of expansion of cement is greater than that of porcelain and this may increase the hazard. In an attempt to lower the coefficient of expansion of the cement ground porcelain was mixed with the cement. The materials were ground together in ball mills in the proportion of one part porcelain to three parts cement. Standard tensile briquettes made from this mixture gave an average of 327 pounds after 48 hours. Suspension insulators assembled with this material gave the same ultimate mechanical strength as when assembled with neat Portland cement. The results of these initial tests are so encouraging that the investigation will be continued.

Abrasion Tests

Probably porcelain that is most resistant to grinding will better resist weathering conditions, the action of acid, moisture, etc. Occasionally, sections from commercial and special insulators are tested to determine their comparative resistance to abrasion.

As an example of the variation, a test of pieces from three commercial insulators of different manufacture is given. The samples were ground under the same pressure and the same area subjected to grinding. The loss in grams per square inch of surface for each minute of grinding was:

No. 1—0.075
No. 2—0.080
No. 3—0.087

It is very apparent that there is a considerable variation in the mechanical structure. Undoubtedly, the individual insulators of any one manufacturer would vary, but the difference is also due to some extent to the materials used and to the factory processes.

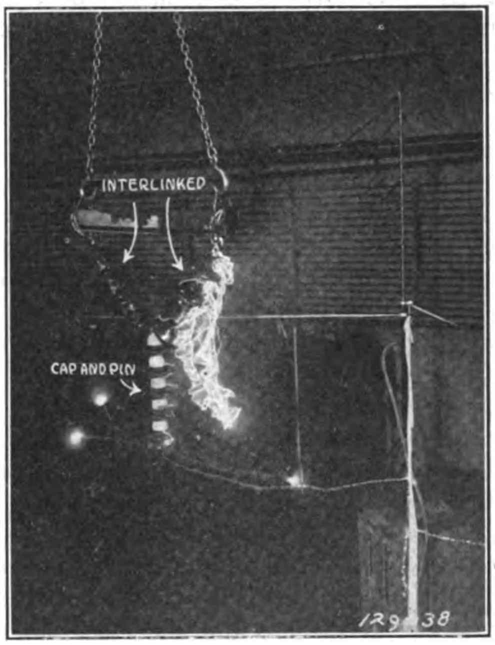

Fig. 18—60-Cycle Wet Flash-Over of Assembled String

Flash-Over Tests

The electrical stress impressed on insulators in line service has been discussed in so many papers that it is entirely unnecessary to go into any detail at this time. The distribution of stress over suspension insulators and the flash-over characteristics of strings of insulators would require a separate paper. Without any special metal fittings to effect a better distribution, the line unit of a string of suspension insulators will assume from

20 to 40 per cent of the total line voltage depending upon the number of insulators in the string, upon the design of the insulator, etc. Many curves of distribution have been published and everyone is familiar with the general shape of these curves which indicate that the line unit or the two units next to the line have much greater than the average stresses impressed upon them.

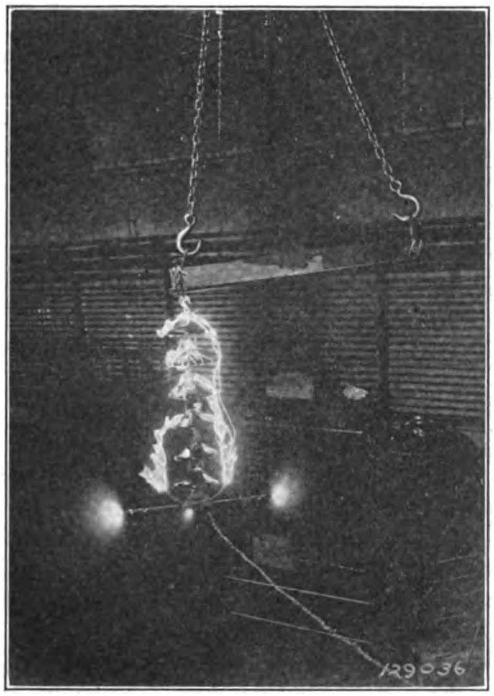

FIG. 19—60-CYCLE FLASH-OVER OF ASSEMBLED STRING

The installation of transmission lines operating at 150 to 220,000 volts, makes it necessary to give careful thought to the concentration of stress upon individual units. The insulators will be subjected to extremely high stresses whenever a flash-over occurs or whenever surges are impressed upon the line from switching, lightning, etc. Fig. 18 is indicative of the stresses from flash-over. This figure shows wet flash-overs on a combination of the interlinked insulators and cap and pin insulators. The interlinked insulators form the *V* part on the string. It is interesting to note the parallel arcs which occur under wet flash-over. Fig. 19 shows a dry flash-over on a string of interlinked insulators. A study of these flash-overs by means of a high-speed camera is giving good results.

CONCLUSIONS

We should at all times consider that porcelain is an extremely fragile material, and that very careful thought must be given to the assembly of porcelain with metal parts, especially if the assembled unit will be subject to severe temperature changes or to mechanical vibrations.

Rapid strides in electrical procelain manufacture have been made during the past few years. Perhaps the greatest advancement is in the methods of production in the factory.

The manufacturers are very open to suggestions from the field and solicit the constructive criticisms which can, perhaps, be given to better advantage by men from the field than by men in the factory. This attitude will continue to react to the mutual advantage of all.

WATER POWER DEVELOPMENT IN QUEBEC

In a review of the industrial and commercial developments in the Province of Quebec, *Commerce Reports* states that the estimated water power available in Canada is some 19,000,000 horse power of which 6,850,000 at 36 per cent is in the Province of Quebec. Of this amount 850,000 have been developed. This has resulted in the creation of such thriving manufacturing towns as Shawinigan Falls, Grand 'Mere, and La Tuque. At Shawinigan Falls, the center of the chemical industry, the electrical generating capacity is 600,000 horse power.

Practically all the electric energy in the Province is now generated by water power and all the large pulp and paper mills, with possibly one exception, are operated by hydroelectric power. Much incentive and assistance is given to water-power undertakings through the activities of the Quebec Streams Commission. The aim of this commission is mainly to improve water-power conditions through water conservation, storage, or otherwise, thus greatly increasing the possible water power available at various sites, thereby rendering them more attractive. The activities of the commission include water conservation storage reservoirs already, constructed and in operation and surveys for future work.

Important additions are reported to be in progress at a number of large hydroelectric plants, such as Cedars on the St. Lawrence, and Shawinigan and Grand 'Mere on the St. Maurice. These extensions aggregate an additional capacity of 130,000 horse power, while a development of 150,000 horsepower is under consideration at Les Gres Falls on the St. Maurice River. The city of Montreal has recently contracted for a large block of power to operate its new electric waterworks pumps, the maximum being 15,000 horse power. The first part of the work in electrifying the harbor railway has been completed; the total trackage is 58 miles, involving an ultimate capacity of some 4000 horse power. A new 800-horse power development to operate rubber works has been completed on the North River at St. Jerome, while new developments or extensions now under construction comprise an addition of 2600 horse power at Deschambault; 2000 horse power at St. Raphael; 4000 horse power at Magog in connection with textile works, and 600 horse power at Lachute.

A Solution of the Porcelain Insulator Problem

By E. E. F. CREIGHTON and F. L. HUNT

General Electric Co., Schenectady, N. Y. Turner Falls Power and Electric Co.

MANY YEARS ago porcelain insulators on transmission lines began to crack in great numbers. In the earlier cases a few disks in many strings had cracked before the transmission engineers had discovered the condition. Indeed, there was at that time no reason to believe that insulators would deteriorate in any way. As a result of these many unobserved failures which simply reduced the factor of safety in each insulator one accidental failure finally introduced surges which punctured many other insulators just on the point of failure. These failures were tens of miles apart. Thereby the whole system was put out of use.

Today these general failures are avoided by a systematic test of each disk at intervals of time depending upon the conditions of installation and the judgment of the transmission engineers.

The cause of most of the failures of these insulators may possibly be reduced to one condition, namely the presence of the Portland cement. To be sure, the Portland cement at times was only indirectly the cause when it simply supplied the moisture which very slowly distilled into porous porcelain. The most usual cause of failure of the disks, however, was due to a characteristic of Portland cement itself. When Portland cement is dried out it shrinks. When it is again wet it expands not only back to its initial size, but a little more. In each cycle of drying and re-wetting the cement increases in volume until it tightly fills the entire space between the metallic hardware and the porcelain. When this condition is reached an unusually warm day will cause an unusual expansion of the metal, and the resulting strain will be transmitted directly through the Portland cement to the porcelain. A crack will result.

Progress in decreasing these failures has been made by the manufacturers of porcelain insulators. For example, instead of resting the cap directly on the porcelain of the usual suspension insulator it is now separated by a slight clearance which prevents the cap from pushing the head off the insulator. This improvement is easily made and has no detrimental factor.

For the expansion of the pin the conditions have been possibly somewhat improved by the use of a layer of soft material next to the porcelain. Unless other conditions are made to conform with this change the insulator is weakened mechanically.

Improvements have been made in the matter of open porosity by greater care in firing. Some manufacturers have also endeavored to overcome this difficulty by glazing all surfaces.

In spite, however, of all of these conditions, the older insulators on transmission lines from all manufacturing companies still fail in sufficient percentages to require the expense of a periodic test and examination. There is an amelioration without a cure. In other words, the life of the insulator has been increased but the tests must still be continued.

The writers attempted to find several solutions of this problem and there is described herewith the satisfactory results of one of these methods. Porcelain disks and hardware were purchased, unassembled, from a reliable manufacturer of insulators. The porcelains were all examined relative to porosity. They were all highly vitrified, in fact there was not the slightest trace of open porosity in a single one of them. A few faults were on the side of overvitrification which manifested itself in a detrimental way by slight checks. Punctures, where they occurred, took place through these checks. Very severe high-frequency voltages were applied by means of the well-known oscillator. The losses due to these extra severe tests were reasonable.

The solution of the main problem—the prevention of failure of the present type of cemented insulators—lies in arresting the expansion of the cement. The easiest method of accomplishing this is by removal of the moisture from the thoroughly set cement and the prevention of its re-entering the cement. This was thoroughly done by impregnation under vacuum on a large number of the insulators and was less thoroughly done on a portion of the insulators with the idea of determining the difference in life, if any, due to the difference in thoroughness of the impregnation.

In the endeavor to reach 100 per cent results it was necessary to study the characteristics of Portland cement when impregnated by different substances. One of the commonest impregnating substances of an insulating nature is paraffin.[1] It was found, however, that a chunk of Portland cement that had been thoroughly impregnated with paraffin by vacuum and heat treatment and then broken would still absorb moisture through the broken surfaces. A better material was therefore looked for. Some of the pitches were found to give perfect results. Portland cement impregnated with pitch could be broken into small pieces and soaked in water for days without the slightest indication of absorption of the water.

As already stated, different methods of impregnation were applied. This work was done in the labora-

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

1. U. S. Pat. 1,360, 896.

tory during 1917 and the spring of 1918. The majority of the insulators were given a thorough vacuum treatment under heat and were impregnated under pressure with the intention and hope of getting 100 per cent perfection and a life of indefinite length—much more than twenty years. In order to get a forecast of the future, laboratory processes of aging were developed. A large wheel, twelve feet in diameter, which is known in the laboratory as the Ferris wheel, was made and operated with the axis in a horizontal plane. Around the rim insulators were secured with bolts and these insulators were passed through a cooling box next to the floor and a heating chamber near the ceiling. The insulators were exposed to the air between these two extremes of heat and an actual blast of moist air was turned on them as they slowly moved around. Here was a device then that gave the extremes of temperature and moisture from 20 deg. cent. below zero to 120 deg. cent. above. The range of temperature and moisture was exaggerated and the rate of change of temperature and moisture was also exaggerated above that found in practise with the idea of hastening any effect that might develop in actual practise. It was estimated that the effect of a single revolution on this wheel would give the insulator more severe strain than would take place in six months in practise—in other words, that two revolutions were equivalent to a year. In this way artificial tests were made extending over more years than any of us will live to enjoy.

In criticism of this method it should be pointed out that it does not give a thorough test of the distillation of moisture into porous porcelain, but it has already been pointed out that these insulators were absolutely without open pores and that consequently that particular feature was not of interest.

Another set of tests was made on these insulators which was more severe in the rate of change of temperature, namely by changing from boiling water to freezing water every half-hour. By these methods we satisfied ourselves that the inpregnation was effective and that the insulators were ready for installation.

The Most Important Conclusions to Date

Eleven hundred of these insulators, carefully marked, were installed on a 66,000-volt transmission line near the seashore in New England in July and August, 1918, and put into operation in November, 1918. *Up to the present time there has not been a single failure among the lot.*

Thirty-six hundred other insulators of the same design, and built in the same factory, were shipped direct from the factory, having been assembled at the insulator factory, and installed on the same line at the same time as the others.

A test made on the whole line about a year after it was put into operation showed 13½ *per cent of failures among the insulators* which came direct from the insulator factory and *no failure at all on those which had received the above described treatment.* The insulators were then about two years old.

Up to the present time there have been additional failures, amounting to 2 or 3 per cent, among the insulators which came direct from the factory, but no failures whatever in the insulators in which the cement was treated.

Following are some comments relating to (1) the mechanical strength, (2) electrical tests treatment, (3) line testing, (4) aging of porcelain, and (5) open porosity of porcelain—which seem pertinent to the subject in hand.

1. *Mechanical Strength.* In discussing the mechanical strength of insulators as affected by impregnation of the cement, it is desirable to avoid the introduction of other factors which are independent of the treatment of the cement. For example, it is well-known that the geometrical dimensions play a leading part in determining the mechanical strength. A large head and a deep pin-hole give more bearing surface for the cement and thereby increase the ultimate "pull" on the hardware. Therefore a type of disk and hardware will have a fairly definite mechanical strength if the cementing is done in the most favorable way.

If the cement is sufficiently set to transmit the force to give the ultimate strength of porcelain in tension (about 2000 pounds per square inch, 140 kg. per square centimeter) and, furthermore, fills the space between hardware and porcelain surfaces sufficiently snugly to transmit the mechanical force uniformly, what more can be asked of the cement? The type of insulator will then give its maximum mechanical "pull."

To arrive at this desired condition the manufacturing details depend on the application of a few scientifically determined factors. To illustrate briefly: The problem of attaining the proper conditions of the cement was approached by experimenting first with the two extremes. At one extreme the cement was set rapidly in live steam at a pressure of 120 pounds per square inch (8.5 kg. per square centimeter). Most of the disks came out of this treatment with the porcelain cracked due to the expansion of the Portland cement. At the other extreme the cement was set for a few days only under conditions of normal room temperature. As a result, either the pin slipped out of the cement in the "pull" test (as was usual) or the cap slipped over the cement. Sufficient "set" and "snugness" of the cement may be obtained by a manipulation of the factors at either extreme—less time and steam temperature starting from the upper extreme or more time and temperature starting from the lower extreme.

It is impracticable to give details here in this brief account. The treatment must be adjusted to the type of cement. For example, some of the grey cements seems to have common characteristics. It is possible

that refinements in the research would show variations in the cement of the same manufacturer at different times of manufacture. We did not go that far. White cement showed the greatest expansion.

The important point in the proposed solution of this problem is that when the cement is given a desirable "set" and "fit" the impregnation excludes moisture which would otherwise change the optimum conditions as the cement grew older. The impregnating material must, of course, be of such a chemical nature as not to attack the cement. If the factors which cause changes in the cement are excluded why will not the cement remain constant forever?

2. *Electrical Tests.* The insulators at the factory and also the specially treated ones in the laboratory were given severe high-frequency tests. Those authorities who have expressed their fear of permanent damage to the porcelain body by the severe electrical tests may feel inclined to explain the loss of over 13 per cent in only two years of life by attributing it to the severity of the tests. This would seem hardly tenable ground. The insulators with impregnated cement were also given the severe electrical tests and none has failed. Is it not more probable that in the assembly of porcelain and hardware in the factory the particular cement and the particular treatment of it expanded the cement to a snug fit and the alternate dry and moist winds of the New England coast caused a further expansion of the tightly fitting cement, followed by a resulting breakage of the porcelain?

3. *Line Testing.* Again it is desirable to emphasize the fact that 100 per cent perfect insulators are a good investment financially, while the extra money expended in *improving* the insulator is of questionable economy. In one case the expensive and dangerous line tests are not necessary, whereas in the other case the line tests are still necessary although they may be made somewhat less frequently. It takes just as long to test 1000 insulators containing one defective as with a number of defectives. The goal is *no testing.*

4. *Aging of Porcelain.* The aging of porcelain is a question frequently brought up. Distinction should be carefully made between the deterioration of insulators and the deterioration of porcelain. There can be no question regarding the former. There is, however, a grave question whether porcelain in itself deteriorates with age. The series of tests of the application of heat, cold, and moisture to normal porcelain, which may be described at a later date, gave not the slightest indication of any change in the porcelain structure. By normal porcelain is meant the combination of clay, feldspar, and flint in the proportion of about 5, 3 and 2 respectively and fired to a vitrification sufficient to do away with open pores. The time and temperature are of the order of 4 to 6 hours at about 1330 deg. cent. The tests used to discover any possible changes in the porcelain were: puncture tests on 60 cycles and 200,000 cycles, hysteresis tests, and impregnation tests of dyes on broken pieces of the porcelain. While it is tenable that improperly made porcelain, using certain grades of quartz instead of flint and introducing other foreign chemicals, such as might come in the ball clay or other ingredients, may deteriorate in time, we have not yet found any such results in our researches. Porcelain protected by glaze is naturally free from moisture. It is therefore, in an insulator, subjected only to the range of atmospheric temperature and the mechanical strains due to the suspended transmission lines. While silica assumes a number of molecular conditions at unusually high temperatures there seems little likelihood that molecular changes at atmospheric temperatures could be a source of deterioration. The chance of deterioration is such a slight factor as compared to more evident conditions that we may properly relegate it to a secondary position for the present in analyzing the faults in porcelain insulators. To be sure, if the porcelain is openly porous and moisture is gradually distilled into the pores and is there frozen, the expansion of the moisture in the cells of the porcelain may increase the porosity. This is not an argument proving the deterioration of porcelain with age, but an argument favoring the proper vitrification of the porcelain, and the glazing of the surfaces exposed to moisture to take care of those inevitable cases of slight undervitrification.

5. *Open Porosity of Porcelain.* In conclusion it should be noted that the use of dry impregnated cement solves also the problem of deterioration of resistance of porcelain due to the absorption of moisture.

As an incidental auxiliary matter, the manufacturer, by request, supplied a few special, underfired insulators for comparison and a method of determining the underfired condition, without destroying the porcelain, was tried. This laboratory test was of the nature of hysteresis loss in the material. A description of it is out of the scope of the present paper. None of these was installed.

Final Comments. Three to four years is not sufficient time to furnish absolute proof of the success of this impregnation method. More reliance is placed on the artificial aging test of the laboratory. There are points for discussion and debate and more work yet to be done. We present the matter as a progressive step.

Transformers for Interconnecting High-Voltage Transmission Systems

For Feeding Synchronous Condensers from a Tertiary Winding

BY J. F. PETERS and M. E. SKINNER

Both of the Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

Owing to the advantages to be realized from the use of the star-star connection in interconnecting high-voltage transmission systems and from the fact that this connection requires the use of an auxiliary winding connected in delta to stabilize the neutral point or to decrease the inductance in the ground connection, a great majority of the transformers designed for interconnecting transmission lines are three-winding transformers. Another type of transformer which would be included in this general class would be that having an auxiliary winding for feeding a synchronous condenser used in controlling the voltage at the receiver end of the line.

Many of the alternatives such as the choice between self-cooling or water-cooling, or between single-phase units and three-phase units, differ in no way from the same questions on transformers for ordinary service. However, there are a number of important features peculiar to three-winding transformers for these classes of service that complicate the design and operation to an extent that justifies special consideration of these problems.

This paper will call attention to these special problems and indicate the way in which the design and performance of transformers for these classes of service are influenced by them.

Phase Displacement Between Interconnected Systems

If TWO transmission systems are tied in at one point only, the phase displacement between the two systems is fixed by the transformer connection which is used at that point. Future interconnections between the two systems must be consistent with those which have preceded them. A 30-deg. phase displacement would require the use of a delta-star connection. A 0-deg. or 180-deg. phase displacement would require the use of either the delta-delta or the star-star connection. The most common condition is probably 0-deg. phase displacement in which case there is a choice between the use of the delta-delta or the star-star connection. The logical choice between these two alternatives is the star-star connection for the following reasons:

First. It reduces the average insulation stress between the windings and the core of the transformer.

Second. It offers an opportunity to ground either or both the system neutrals at the transformer.

Third. It results in a cheaper and smaller transformer.

Fourth. It offers an opportunity for further reduction in first cost when the neutrals are grounded by the use of graded insulation.

Fifth. It offers an opportunity for further reduction in first cost by the elimination of one high-voltage bushing.

Economy of Star-Connected Transformers

The average voltage stress between windings and core is 43.3 per cent of the line voltage in a delta-connected winding, but only 28.9 per cent in a star-connected winding, the latter figure being just two-thirds of the former.

A star-connected transformer is cheaper to build than a delta-connected one because of the better space factor resulting from the fewer number of turns of correspondingly larger cross-section. The difference between the costs of the two is a function of the voltage and of the capacity of the transformer, and becomes more marked as the voltage increases and the capacity decreases. The dry weight of a transformer, *i. e.*, the weight of the transformer with its case but exclusive of the oil, is sometimes used as a criterion of the cost of transformers. Fig. 1 shows the relation between the dry weights of star- and delta-connected

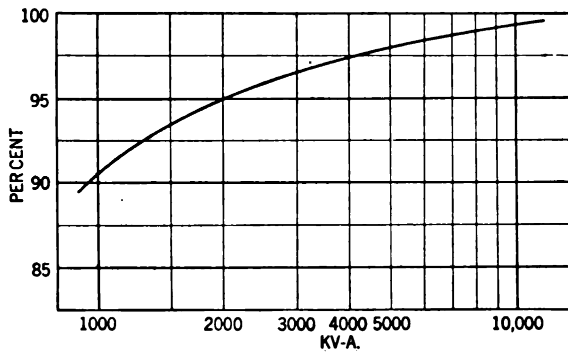

Fig. 1—Dry Weight of One-Phase, 60-Cycle, 66-Kv. Star-Connected Transformers in Per Cent of Equivalent Delta-Connected Transformers

single-phase, 60-cycle, 66,000-volt transformers, and the kv-a. of the transformer. The dry weight of the star-connected transformer is expressed as a percentage of the dry weight of the delta-connected transformer of the same rating. The saving of the star connection over the delta connection is evident from this curve. For higher voltage classes the differences would be still more marked, while for very low voltages they become negligible. In fact, for extremely low voltages the heavier current may be a handicap and throw the difference in favor of the delta connection. The economies effected through the use of the

star connection for high voltages often result in a reduction in the dimensions as well as the cost.

When the neutral of the system is directly grounded at both ends of the line it is often the practise on star-connected transformers to taper the insulation between the windings and the core more or less in proportion to the stress between them and to test them with an induced voltage rather than a disruptive test. The Standardization Rules of the A. I. E. E., Article 6361-e, specify the test for apparatus connected to permanently grounded single-phase circuits of more than 300 volts as 2.73 times the voltage to ground + 1000 volts, but the same rule specifically states that this test shall not apply on three-phase apparatus with grounded star neutral. However, where transformers have been supplied in the past with graded insulation, the practise has been to apply the same rule to three-phase circuits until this practise is now pretty well established. Grading the insulation between winding and core proportionately with the stresses, results in a considerable saving and makes it possible to eliminate one of the high-voltage bushings. The cost of high-voltage bushings is quite an item and the increased clearances possible with only one high-voltage bushing through the cover make for greater safety.

Star-Star Connection is Adapted to the Use of Auto-Transformation

An auto-transformer offers a decided saving in first cost over an equivalent transformer with separate windings but it can only be applied under certain conditions. These conditions are fulfilled with the star-star connection when the neutral point is directly and permanently grounded. If the neutral of the three-phase star-star connected auto-transformer is not directly and permanently grounded, serious stresses will be put upon the system having the lower line voltage in the event of one of the higher voltage lines grounding accidentally. Assume a three-phase star-star connected auto-transformer stepping down from 150,000 volts and 66,000 volts with the neutral free. In the event of a ground on one of the 150,000-volt lines the potential of the 66,000-volt lines above ground would be increased from 38,100 volts to 48,500 volts on the line in the same phase on which the ground occurs and to 110,800 volts on the other two lines. (Fig. 2.)

The amount of saving effected by the use of auto-transformers as compared with transformers with separate windings depends upon the ratio of transformation. The equivalent size of the auto-transformer to transform a certain kv-a. expressed as a fraction of the kv-a. is $\frac{V_1 - V_2}{V_1}$ where V_1 and V_2 are the higher and lower voltages respectively. It is evident from this expression that the greatest reduction in size and cost occurs when V_1 and V_2 are of nearly the same magnitude. If this were the only consideration, the most likely field of application for an auto-transformer would be where the ratio of transformation is nearly unity. However, the impedance of an auto-transformer is lower than that of an equivalent transformer with separate windings, in the same ratio as the equivalent size is reduced, namely $\frac{V_1 - V_2}{V_1}$ so that as V_2 approaches V_1 the impedance approaches O. The low impedance of the auto-transformers in the range of voltage ratios where they present the greatest economy works against them as it allows very heavy currents to flow through them at times of short circuits. When the transformation ratio falls much below 1 to 1.1 it becomes almost impossible to design an auto-transformer which will be self-protecting, *i. e.*, will withstand the forces incident to a dead short circuit with sustained voltage without mechanical injury. The result of this situation has been to limit the application of auto-transformers to that range of voltage ratios where the stresses due to short circuits are within reasonable limits. A review of the past applications of auto-transformers to power transmission systems indicates that the majority of such applications has been where the ratio of transformation was in the vicinity of two to one.

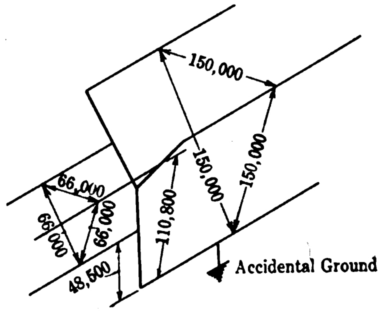

Fig. 2—Voltages to Ground with Star-Star Auto-Transformers and Neutral Free

The economy of the star-star connection, the availability of ground connections, and its adaptability to the use of graded insulation and auto-transformations, gives it a great advantage over the delta-delta connection for use in interconnecting power systems and it has been used almost exclusively in the past where 0-deg. phase displacement is desired.

Star-Star Connection Requires the Use of Auxiliary Winding Connected in Delta

When the star-star connection is employed it is necessary to have an auxiliary or tertiary winding connected in delta to obtain satisfactory operation.[1] In all single-phase transformers and in three-phase transformers of the shell type of construction, a tertiary is necessary in order to supply the triple harmonic component of the exciting current which is suppressed

1. See paper on this subject by Mr. J. F. Peters, Proc. A. I. E. E., August, 1915.

by the star-star connection. If the triple harmonic exciting current is not supplied there will be a triple harmonic in the phase voltage which will produce an unstable neutral. This cannot be permitted on account of the insulation stresses imposed on the system. In the three-phase core type of construction the return circuit for the flux in any leg is through the other two legs. The deficiency in third harmonic excitation in any phase at any given instant is supplied from the other two phases which have an excess of third harmonic excitation at that instant. There are other considerations which will be discussed later, under the effect of the tertiary upon the currents which flow when a high-voltage line accidentally grounds, which make advisable the addition of a tertiary winding in the three-phase core-type transformer even though it is not required to stabilize the neutral.

Use of a Tertiary Winding to Furnish Power for a Synchronous Condenser

A tertiary winding is often used to furnish power to a synchronous condenser used for regulating the voltage at the receiver end of a transmission line. It is often possible to effect a considerable saving by having the transformer, which would be required for the synchronous condenser, combined with the main step-down transformer.

When a condenser is supplying leading kv-a. and the main load is at a lagging power factor the two loads combine to reduce the current flowing in the primary so that the addition of the condenser winding will not increase the size of the primary winding as long as the condenser does not exceed twice the reactive component of the main load. If the condenser load were maintained at all times, it would even be possible to reduce the size of the primary. This is seldom the condition, however, and it is therefore the practise to design the primary so that it will carry full load with the condenser shut down.

The third winding in a transformer, whether it be for stabilizing the neutral point or for reducing the inductance in the connection between neutral and ground in a star-star connected bank or for supplying power to two loads of different power factors, introduces many features which must be recognized in the design and considered in predicting the operating characteristics of such transformers.

Limitations Imposed on Grouping of the Windings

When transformers tie together three systems where the flow of power may be from any one to the other two or vice versa, one of the first requirements is that the reactance between any two windings be of about the same magnitude. If this is not the case, there will be large differences between the regulation with varying conditions of power flow between the interconnected systems. Moreover, with power supply on all three systems, if the reactance is low between any two of them, the currents flowing under short-circuit conditions will become dangerously large and there will be danger of mechanical injury to the transformer. Thus the problem is one of getting high enough reactance between any two windings without making that between any other two excessive.

In the single-phase concentric-coil core type of construction there are two ways in which the three windings may be arranged with respect to one another.

The first arrangement, Fig. 3a, will result in normal reactance between primary and secondary and between secondary and tertiary, but in very high reactance between the primary and the tertiary due to the greater separation and the resultant heavy leakage across the space occupied by the secondary winding. In the second arrangement, Fig. 3b, by making the disposition of the windings on the two legs different it is possible to equalize the reactances between pairs of the windings. This is a rather dangerous compromise however, because the leakage flux between any pair

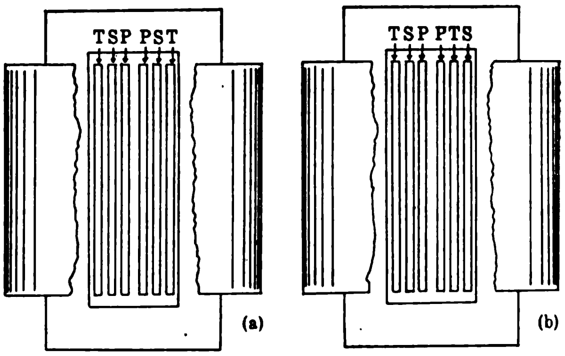

Fig. 3—Partial Section Through Core-Type Transformer Showing Disposition of Windings

of windings in one direction on one leg is greater than that returning on the other leg. The excess will have to return through the space surrounding the transformer and would result in an intolerable condition due to the heating caused by the stray flux. If the loads on both secondaries happened to be in phase the condition would be improved as then the sum of the leakage would be the same on both legs. This is a condition which would be difficult if not impossible of accomplishment under operating conditions. With loads of different power factors the leakage flux between one secondary and the primary would be out of phase with that between the other secondary or tertiary and the primary resulting in the condition just described. In a three-phase concentric-coil core-type transformer there is no alternative but to submit to a high reactance between one pair of windings inasmuch as all the winding for one phase is on one leg.

In a shell-type transformer it is possible on account of the more extensive interlacing of the windings to equalize the reactance between all pairs of windings without causing heavy stray fields through the unbalancing of the leakage flux.

Refer to Fig. 4 and note that each half of the trans-

former is balanced in itself, *i e.*, the total leakage between P_1 and S is the same on the left side of P_1 as on the right side. The total leakage between P_2 and S is also the same on either side but its magnitude is different from that about P_1. The location of T with respect to P in one-half of the opening is the same as that of S in the other half so that the reactance

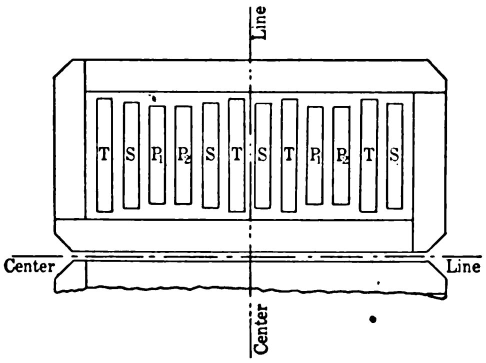

FIG. 4—PARTIAL SECTION THROUGH SHELL-TYPE TRANSFORMER SHOWING DISPOSITION OF WINDINGS

between any pair of windings will be substantially the same without creating an unbalance which will result in heavy leakage fields.

From the foregoing discussion it is quite evident that to design a three-winding transformer to meet certain specified values of reactance between each pair of windings would impose conditions which are extremely difficult and sometimes practically impossible to fulfill. This might be the condition presented to the designer if called upon to design a three-winding transformer to operate in parallel with another unit of different rating.

REGULATION OF THREE-WINDING TRANSFORMERS

A three-winding transformer will usually have different voltage drops from primary to secondary and

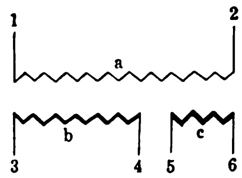

FIG. 5

from primary to tertiary. Moreover, the voltage drop between primary and secondary is usually affected by the load on the tertiary so that if the tertiary is loaded there may be a drop from primary to secondary even though the latter winding is idle.

Let the sub-numbers and sub-letters refer to the windings as indicated in the sketch, Fig. 5.

R = resistance in ohms at reference voltage,
L = self-inductance in henrys,
M = mutual inductance in henrys,
E = reference voltage expressed as a complex quantity,
I = current in winding at reference voltage expressed as a complex quantity,
X = reactance between windings

$$= w\,(L_p - 2\,M_{ps} + L_s)$$
$$= 2w\,(L - M) \text{ where } L_p = L_s.$$

The voltage drop in each winding will be:

$$E_{12} = -\,R_a\,I_{12} - j\,w\,(L_a\,I_{12} + M_{ab}\,I_{34} + M_{ac}\,I_{56}) \quad (1)$$
$$E_{34} = -\,R_b\,I_{34} - j\,w\,(L_b\,I_{34} + M_{ab}\,I_{12} + M_{bc}\,I_{56}) \quad (2)$$
$$E_{56} = -\,R_c\,I_{56} - j\,w\,(L_c\,I_{56} + M_{ac}\,I_{12} + M_{bc}\,I_{34}) \quad (3)$$
$$I_{12} = -\,(I_{34} + I_{56}) \quad (4)$$
$$E_{12} = +\,R_a\,(I_{34} + I_{56}) + j\,w\,[L_a\,(I_{34} + I_{56}) - M_{ab}\,I_{34} - M_{ac}\,I_{56}] \quad (5)$$
$$E_{34} = -\,R_b\,I_{34} - j\,w\,[\,L_b\,I_{34} - M_{ab}\,(I_{34} + I_{56}) + M_{bc}\,I_{56}] \quad (6)$$
$$E_{56} = -\,R_c\,I_{56} - j\,w\,[\,L_c\,I_{56} - M_{ac}\,(I_{34} + I_{56}) + M_{bc}\,I_{34}] \quad (7)$$

The voltage drop from winding a through winding b:

$$-\,(E_{12} - E_{34}) = (R_a + R_b)\,I_{34} + j\,w\,(L_a - 2\,M_{ab} + L_b)\,I_{34} + R_a\,I_{56} + j\,w\,(L_a - M_{ac} - M_{ab} + M_{bc})\,I_{56} \quad (8)$$

Adding $1/2\,j\,w\,(L_b - L_b + L_c - L_c)\,I_{56}$ and recombining,

$$= (R_a + R_b)\,I_{34} + j\,w\,(L_a - 2\,M_{ab} + L_b)\,I_{34} + R_a\,I_{56} + 1/2\,j\,w\,[\,(L_a - 2\,M_{ab} + L_b) + (L_a - 2\,M_{ac} + L_c) - (L_b - 2\,M_{bc} + L_c)\,]\,I_{56} \quad (9)$$

but, $w\,(L_p - 2\,M_{ps} - L_s)$ is the reactance between primary and secondary, then,

$$-\,(E_{12} - E_{34}) = [\,(R_a + R_b) + j\,X_{ab}\,]\,I_{34} + [R_a + 1/2\,j\,(X_{ab} + X_{ac} - X_{bc})\,]\,I_{56} \quad (10)$$

in the same way

$$-\,(E_{12} - E_{56}) = [\,(R_a + R_c) + j\,X_{ac}]\,I_{56} + [R_a + 1/2\,j\,(X_{ab} + X_{ac} - X_{bc})\,]\,I_{34} \quad (11)$$

These voltage drops will appear as complex quantities and may be reduced to percentage by dividing by the reference voltage E. They will then be in the form

$$\pm\,a\,\% \pm j\,b\,\%.$$

Then

$$\%\text{ Regulation} = \pm\,a\,\% + \frac{(\pm\,b\,\%)^2}{200} \quad (12)$$

The sign of the regulation may be positive or negative, a positive sign indicating a drop and a negative sign a rise in voltage as the load is increased.

It will be noticed that in each voltage drop there is a term which depends upon the current which flows in the winding which is not being considered, for instance, in the voltage drop from winding a to winding b there is a component produced by the flow of the current I_{56} in winding c. This indicates that there will be a certain amount of regulation on a winding even at no-load, providing load is being taken from one of the other windings. The condition under which this influence will be a minimum is that $X_{ab} + X_{ac} = X_{bc}$.

The following tables will indicate in a general way how changes in load affect the regulation of a typical

three-winding transformer. The transformer chosen is typical of the type under consideration. It is a 35,000-kv-a., single-phase, 60-cycle, star-star connected transformer designed to step down 30,300 kv-a. at 100 per cent power factor, from 220 kv. to 66 kv. and to supply a synchronous condenser of 17,500-kv-a. capacity at 13 kv., the tertiary winding being connected in delta.

TABLE I

Regulation in per cent with varying condenser load. Load on 66-kv. winding constant at 30,300 kv-a. 100 per cent power factor.

Application of Formulas to Auto-Transformers

It has been pointed out that the star-star connected auto-transformer with a tertiary winding is a special case of three-winding transformers.

Following the same system of notation and referring to Fig. 6, note that there are three conditions of loading.

(A) Winding 13 delivering power to, or receiving power from, windings 23 and 45.

(B) Winding 23 delivering power to, or receiving power from, windings 13 and 45.

(C) Winding 45 delivering power to, or receiving power from, windings 13 and 23.

Case A. Let I with proper subscript = current due to load on auto-transformers.

Let I' with proper subscript = current due to load on two-winding transformer.

$$\begin{aligned} E_{13} = &- R_a I_{12} - R_b I_{23} - (R_a + R_b) I_{13}' \\ &- j w (L_a I_{12} + L_b I_{23} + M_{ab} I_{12} + M_{ab} I_{23} \\ &+ L_{ab} I_{13}' + M_{ab\text{-}c} I'_{45}) \end{aligned} \tag{13}$$

$$\begin{aligned} E_{23} = &- R_b (I_{23} + I_{13}') - j w [L_b (I_{23} + I_{13}') \\ &+ M_{ab} (I_{12} + I_{13}') + M_{bc} I_{45}'] \end{aligned} \tag{14}$$

$$\begin{aligned} E_{45} = &- R_c I_{45}' - j w (L_c I_{45}' + M_{ac} I_{12} + M_{bc} I_{23} \\ &+ M_{ab\text{-}c} I_{13}') \end{aligned} \tag{15}$$

In order to handle the ratio between windings $a\,b$ and b it is necessary to introduce a factor r.

Let $$\frac{E_{13}}{E_{23}} = r = \frac{E_{12} + E_{23}}{E_{23}} = \frac{E_{12}}{E_{23}} + 1,$$

then $$\frac{E_{12}}{E_{23}} = (r - 1)$$

and $$\frac{I_{12}}{I_{23}} = \frac{1}{r - 1} \text{ or}$$

$$I_{23} = - (r - 1) I_{12}; \text{ also, } I_{45}' = - I_{13}'$$

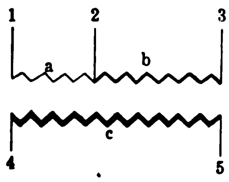

Fig. 6

Then,

$$\begin{aligned} E_{13} = &- [R_a - (r - 1) R_b] I_{12} - R_{ab} I_{13}' - j w [L_a I_{12} \\ &- (r - 1) L_b I_{12} + (2 - r) M_{ab} I_{12} + L_{ab} I_{13}' \\ &- M_{ab\text{-}c} I_{13}'] \end{aligned} \tag{16}$$

$$\begin{aligned} E_{23} = &R_b [(r - 1) I_{12} - I_{13}'] + j w [L_b (r - 1) I_{12} \\ &- L_b I_{13}' - M_{ab} (I_{12} + I_{13}') + M_{bc} I_{13}'] \end{aligned} \tag{17}$$

$$\begin{aligned} E_{45} = &R_c I_{13}' + j w [L_c I_{13}' - M_{ac} I_{12} \\ &+ (r - 1) M_{bc} I_{12} - M_{ab\text{-}c} I_{13}') \end{aligned} \tag{18}$$

The voltage drop from winding a through winding b:

$$\begin{aligned} - (E_{13} - r E_{23}) = &[R_a + (r - 1)^2 R_b] I_{12} \\ &+ j w [L_a - 2 (r - 1) M_{ab} + (r - 1)^2 L_b] I_{12} \\ &+ (R_{ab} + r R_b) I_{13}' + j w (L_{ab} - M_{ab\text{-}c} - r L_b \\ &- r M_{ab} + r M_{bc}) I_{13}' \end{aligned} \tag{19}$$

Adding $1/2 j w (L_c - L_a + r^2 L_b - r^2 L_b) I_{13}'$ and recombining and making use of the relation

$$1/2 L_{ab} = 1/2 (L_a + 2 M_{ab} + L_b)$$

$$\begin{aligned} = &[R_a + (r - 1)^2 R_b] I_{12} + j w [L_a - 2 (r - 1 M_{ab} \\ &+ (r - 1)^2 L_b] I_{12} + (R_{ab} + r R_b) I_{13}' \\ &+ j w 1/2 (L_{ab} - 2 M_{ab\text{-}c} + L_c) I_{13}' + j w 1/2 [L_a \\ &- 2 (r - 1) M_{ab} + (r - 1)^2 L_b] I_{13}' - j w 1/2 (L_c \\ &- 2 r M_{bc} + r^2 L_b) I_{13}' \end{aligned} \tag{20}$$

$$\begin{aligned} = &[R_a + (r - 1)^2 R_b] I_{12} + j X_{ab} I_{12} \\ &+ (R_{ab} + r R_b) I_{13}' + j 1/2 (X_{ab\text{-}c} + X_{ab} \\ &- X_{bc}) I_{13}' \end{aligned} \tag{21}$$

Similarly, the voltage drop from winding a through winding c

$$-(E_{13} - E_{45}) = (R_{ab} + R_c)\, I_{13}' + j\, X_{ab\cdot c}\, I_{13}' + [R_a - (r-1)\, R_b]\, I_{12} + j\, 1/2\, (X_{ab\cdot c} + X_{ab} - X_{bc})\, I_{12} \qquad (22)$$

The regulation may be obtained from these voltage drops in the same way as from equations (11) and (12).

CASE B. Developing this case in exactly the same way results in expressions as follows. The voltage drop from winding b through winding $a\,b$:

$$(r\, E_{23} - E_{13}) = [R_a + (r-1)^2\, R_b]\, I_{12} + j\, X_{ab}\, I_{12} + r\,(r-1)\, R_b\, I_{45}' + j\, 1/2\, (X_{ab} + X_{bc} - X_{ab\cdot c})\, I_{45}' \qquad (23)$$

The voltage drop from winding b through winding c:

$$(r\, E_{23} - E_{45}) = (R_c + r^2\, R_b)\, I_{45}' + j\, X_{bc}\, I_{45}' + r\,(r-1)\, R_b\, I_{12} + j\, 1/2\, (X_{ab} + X_{bc} - X_{ab\cdot c})\, I_{12} \qquad (24)$$

CASE C. In the same manner under this condition the drop from winding c through winding $a\,b$:

$$-(E_{45} - E_{13}) = (R_c + R_{ab})\, I_{45} + j\, X_{ab\cdot c}\, I_{45} + (R_c + r\, R_b)\, I_{45}' + j\, 1/2\, (X_{ab\cdot c} + X_{bc} - X_{ab})\, I_{45}' \qquad (25)$$

and the drop from winding c through winding b:

$$-(E_{45} - r\, E_{23}) = (R_c + r^2\, R_b)\, I_{45}' + j\, X_{bc}\, I_{45}' + (R_c + r\, R_b)\, I_{45} + j\, 1/2\, (X_{ab\cdot c} + X_{bc} - X_{ab})\, I_{45} \qquad (26)$$

Referring back to Fig. 5, assume a short circuit occurs on winding a. Let $R_b' + j\, X_b'$ and $R_c' + j\, X_c'$ represent the impedance of the lines and generators connected to windings b and c, respectively. Including these impedances in the voltage drops as given by equations (10) and (11) we have:

$$-(E_{12} - E_{34}) = [\,(R_a + R_b + R_b') + j\,(X_{ab} + X_b')\,]\, I_{34} + [R_a + 1/2\, j\,(X_{ab} + X_{ac} - X_{bc})\,]\, I_{56} \qquad (27)$$

$$-(E_{12} - E_{56}) = [\,(R_a + R_c + R_c') + j\,(X_{ac} + X_c')\,]\, I_{56} + [R_a + 1/2\, j\,(X_{ab} + X_{ac} - X_{bc})\,]\, I_{34} \qquad (28)$$

Putting

$$Z_2 = R_a + R_b + R_b' + j\,(X_{ab} + X_b') \qquad (29)$$

$$Z_3 = R_a + R_c + R_c' + j\,(X_{ac} + X_c') \qquad (30)$$

$$Z_0 = R_a + 1/2\, j\,(X_{ab} + X_{ac} - X_{bc}) \qquad (31)$$

Equations (27) and (28) may be rewritten:

$$-(E_{12} - E_{34}) = Z_2\, I_{34} + Z_0\, I_{56} \qquad (32)$$

$$-(E_{12} - E_{56}) = Z_3\, I_{56} + Z_0\, I_{34} \qquad (33)$$

Since the drop is the same in both circuits,

$$E = Z_2\, I_{34} + Z_0\, I_{56} = Z_3\, I_{56} + Z_0\, I_{34} \qquad (34)$$

and,

$$I_{34} = \frac{Z_3 - Z_0}{Z_2\, Z_3 - Z_0^2}\, E \qquad (35)$$

$$I_{56} = \frac{Z_2 - Z_0}{Z_2\, Z_3 - Z_0^2}\, E \qquad (36)$$

and adding,

$$I_{12} = \frac{Z_2 + Z_3 - 2 Z_0}{Z_2\, Z_3 - Z_0^2}\, E \qquad (37)$$

The most satisfactory method of calculating short-circuit currents in a complicated network is by the

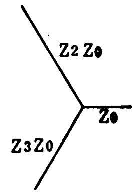

FIG. 7—GRAPHICAL REPRESENTATION OF IMPEDANCES IN A THREE-WINDING TRANSFORMER

use of a calculating board, *i. e.*, by setting up a network of resistances whose values are proportional to the impedances of the various parts of the system, impressing a known voltage, and measuring the currents which flow in the various branches of the network. From these measurements the magnitudes of the actual short-circuit currents are calculated. It is interesting to note from equations (27) and (28) how a three-winding transformer would be set up on such a calculating board. One component of impedance is common to both $-(E_{12} - E_{34})$ and $-(E_{12} - E_{56})$ so that the three-winding transformer may be represented by a three-legged star with legs respectively Z_0, $Z_2 - Z_0$ and $Z_3 - Z_0$. (Fig. 7).

EFFECT OF A TERTIARY WINDING IN LIMITING CURRENT WHICH FLOWS WHEN ONE LINE ACCIDENTALLY GROUNDS

In a star-star connected transformer with a tertiary winding and with the neutral grounded on either or both of the high and low-voltage sides but with the

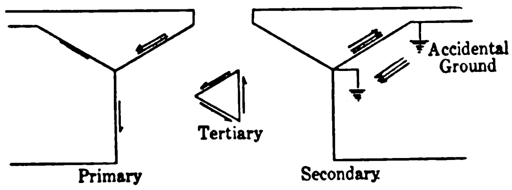

FIG. 8—FLOW OF CURRENT WHEN SECONDARY LINE GROUNDS—STAR-STAR CONNECTION WITH TERTIARY

neutral of the supply not grounded, the magnitude of the current which flows in case of an accidental ground on one of the lines is influenced very largely by the reactance between the main windings and the tertiary. In a transformer with a 1 to 1 turn ratio between all windings the current in the tertiary will always be one-third of the current flowing to ground on the secondary side because this is the only division of current which makes the ampere turns of primary

and secondary equal in each phase. Refer to Fig. 8 which shows quantitatively how the currents would divide under the conditions shown.[2] The ampere turns of phase A on the grounded side are balanced by those in phase A on the primary side and by those in phase $A\,C$ in the tertiary. The conditions which determine the division of current are that the current in each leg of the tertiary be the same since it flows in series through each of them, and that the sum of the currents in phases B and C on the primary side be equal to the current in phase A since the current is a single-phase current. The only way current can divide between phases B and C and fulfill these conditions is to divide equally. Since the currents in phases B and C of the grounded side carry no current, that which flows in the same phases of the primary side must be all balanced by the current in the same phase of the tertiary.

The total magnitude of the ground current usually depends partly upon the impedance of the generators supplying the line to the unbalanced currents which flow through them under such conditions. For this reason it is difficult to calculate accurately as these special impedance measurements are seldom at hand. It is quite evident however that with large capacity back of the transformer, the impedance of the generator and supply lines is relatively small, and the magnitude of the current which flows depends largely upon the impedance between various pairs of windings in the transformer, and may be closely approximated by neglecting the generator and supply line impedance and assuming full voltage maintained. Under this assumption the currents flowing under various combinations of grounding will be as given in Table IV.

I_n = normal current in winding at full load.

Z_o = impedance voltage between primary and secondary in per cent at full load.

Z_t = impedance voltage between primary or secondary and tertiary in per cent at a load in the tertiary corresponding to full load, depending upon the winding under consideration.

2. See Article in the *Elec. Journal*, Nov. 1919, Tertiary Winding in Transformers, Their Effect on Short-Circuit Currents, by J. F. Peters.

This means that in any of these connections the ground connection has more or less inductance in it. The amount of inductance can be minimized by keeping these same impedances to low values. This fact shows why it is necessary to supply a tertiary winding for a three-phase core-type transformer, if there is no tertiary. The ampere turns in the winding which is grounded are balanced by the ampere turns on the other two legs, and the leakage flux would be very great. This is equivalent to a tertiary with very high reactance and means that the ground current would be limited to a very low value. However, it is limited by what is equivalent to inserting a large inductance in the neutral connection. When a three-phase core-type transformer without a tertiary is under consideration Z_t becomes the impedance voltage between the winding on one leg and the windings on the other two connected in parallel in per cent at full load.

TABLE IV

Connection of Transformer bank					Short-circuit Current	
Primary	Secondary	Supply	Side of which fault occurs	Tertiary	In tertiary	In main winding
Star Grounded	Star Grounded	Grounded	Secondary	No	0	$\frac{100\ I_n}{Z_o}$
Star Grounded	Star Grounded	Isolated	Primary	Yes	$\frac{100\ I_n}{Z_t}$	$\frac{100\ I_n}{Z_t}$
Star Grounded	Star Grounded	Isolated	Secondary	Yes	$\frac{100\ I_n}{2Z_o + Z_t}$	$\frac{300\ I_n}{2Z_o + Z_t}$
Star	Star Grounded	Grounded or Isolated	Primary	Yes	0	0
Star	Star Grounded	Grounded or Isolated	Secondary	Yes	$\frac{100\ I_n}{2Z_o + Z_t}$	$\frac{300\ I_n}{2Z\ + Z_t}$

For this reason all transformers for star-star connection should be equipped with tertiary windings and the impedance between main windings and tertiary should be kept fairly low to avoid the conditions which obtain when there is inductance in the neutral connection. When the tertiary is not designed to supply a load its capacity is determined by the heating conditions imposed by short circuits. For this reason the short-circuit conditions should be carefully investigated and full information furnished the designer.

ELECTRIFIED SUGAR MILL IN CENTRAL AMERICA

It has been decided says *Commerce Reports*, to electrify the new sugar mill of the Sula Sugar Co. at La Lima, Honduras, and plans have been drafted which will make it the largest electrified sugar mi l in Central America. Power will be developed by a 1000-kilowatt turbo-generator set with an auxiliary set of 200 kilowatts for lighting and general purposes. All the electrical equipment will be furnished by an American company and installation will be made by the same American company that is constructing the mill. The fuel to be used for running this system will be cane fodder and scraps, the supply of which is expected to be sufficient. Construction of the new mill is going forward rapidly. The boilers have been set in place and smokestacks and water towers erected. Most of the heavier machinery is also installed and the machine shop is nearly completed. The first cane will be crushed in October.

Notes on Operation of Large Interconnected Systems

BY L. L. ELDEN
Edison Electric Illuminating Co. of Boston

INTERCONNECTIONS have been made between the Boston Edison systems and the systems of the Eastern Massachusetts Electric Company and the New England Power Company, these two companies serving territory adjacent to that served by the Boston Edison Company.

Connection with the former company is effected by a 13,800-volt cable connection between nearby substations of the two companies where transmission facilities were suitable for an interchange of power. The capacity of this connection is limited to 3000 kv-a. by the capacity of the transformers installed in the Eastern Massachusetts Company's substation. The principal generating station of the Eastern Massachusetts Company being located at Salem, Mass., the connection with this station is finally completed via 22,000-volt aerial and underground lines of the E. M. E. Co. Any energy interchanged by the two companies passes through three substations on the Edison system and two substations of the E. M. E. Co., all of which supply local distribution areas.

The connection with the New England Power Company comprises a special transmission line including 25,000-volt underground transmission, 66,000-volt aerial transmission over private right of way, and two banks of step-up transformers each comprising three 5000-kv-a., three-phase, oil-cooled outdoor-type transformers. Switching facilities permit the transformers to be arranged for operation for transmission capacities of 5000 kv-a., 10,000 kv-a., and 15,000 kv-a., respectively as load requirements may dictate.

Connection is made with the N. E. P. Co. at its Clinton substation, from which 66,000-volt lines extend to the several sources of power of that company. These include not only their own hydro and steam stations, but in addition connections with the systems of a number of other public utilities and industrial corporations with which it has reciprocal arrangements for purchase or sale of power.

The physical arrangement of the interconnections with both companies is shown diagrammatically in Fig. 1.

The operation of the connection with the E. M. E. Co. has been uniformly satisfactory, barring some early difficulties initially encountered in adjusting the frequency of the two systems to the required standards and to difficulties encountered in securing suitable relay adjustments on the interconnecting lines. With the elimination of these minor troubles, no other difficulties of moment have been encountered in the daily operation of the two systems other than occasional operation of the relays to disconnect the systems when serious trouble has occurred on either which has resulted in a transfer of energy in excess of the rated capacity of the interconnection. Under normal conditions the E. M. E. Co. is the purchasing company and on several occasions the line has enabled the Boston Company to assist the E. M. E. Co. in emergencies when troubles have occurred at the latter's generating station.

In the operation of the N. E. P. Co. more difficult conditions have been encountered due to the nature and arrangement of the line connections and to the more frequent occurrence of transmission troubles incident to the large amount of 66,000-volt aerial construction exposed to lightning and other line troubles.

Violent fluctuations on both systems have occurred upon the occasion of short circuits on either, the tie line usually opening and separating the systems on such occasions. The extent to which these troubles

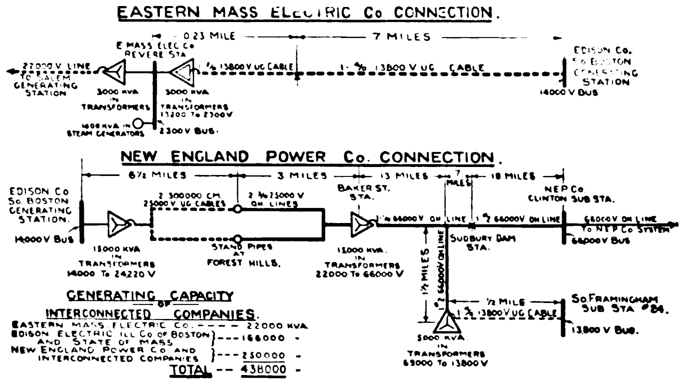

FIG. 1

have affected either system has been entirely dependent upon the generating capacity in service and load on each system at the time of trouble, and in a few cases the results have been rather serious.

Experiments with various relay adjustments have effected some relief, although it now appears that heavy shorts on either system will continue to affect the other in the future as in the past, since there appears no means readily available to eliminate such effects without unfavorably affecting the voltage regulation of the tie line.

In the initial operation of this interconnection certain difficulties developed due to variations in frequency on the N. E. P. Company's system. That company being a large purchaser of energy from companies other than the Edison Company is naturally obliged to accept some modification of standard frequency at times in order that each selling company may deliver the power required for each day's operating schedule. These variations have caused some diffi-

culty in effecting a proper division of the load between the various systems due to the desire of the Edison Company not to depart from its past practise of maintaining a standard frequency of 60 cycles at all times. This is accomplished through the use of the Warren clock for regulating purposes, and has become an important factor in the operation of the system due to the extensive use of Warren clocks as time keeping devices by the company's customers. The company has, therefore, unintentionally drifted into the undesirable position of operating a "time keeping" system which has been so satisfactory to certain users that it has been employed in some locations in place of Western Union time service.

Operation in connection with the N. E. P. Co. has caused some troubles in this direction, although, in general, time keeping errors are small and are corrected by minor changes in frequency over a given period or until normal time conditions are restored.

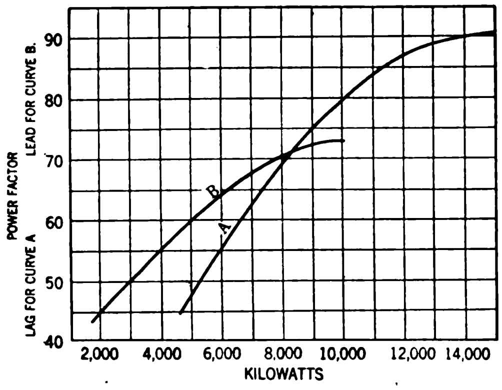

Fig. 2—Power Factor Curves of Interconnecting Transmission Line between the Edison Electric Illuminating Co. of Boston and the New England Power Co.

Curve *A*—Edison Co. supplying power to the N. E. P. Co. at the Edison South Boston Station.

Transformers at Baker St. station connected 22,000 to 66,000 volts.

Curve *B*—Edison Co. supplying power from the N. E. P. Co. at the Edison South Boston station.

Transformers at Baker St. station connected 60,000 to 22,000 volts.

The connection with the N. E. P. Co. as originally conceived was constructed for the delivery of energy to that company, there being no thought of transmitting energy in the reverse direction to the Edison Company beyond substation No. 24 at South Framingham. Variable tap connections were, therefore, provided on the step-up transformers at Baker Street Station to secure proper control of power factor and voltage regulation which have enabled us to secure the results indicated by curve *A* in Fig. 2. It later developed that the Edison Company could purchase so called "freshet power" at times from the N. E. P. Co. under favorable terms, and in accordance therewith a contract was executed for the purchase of such power for delivery during off-peak periods, or when otherwise available.

With the transformers connected for delivery of power to the N. E. P. Co. the conditions for reverse operation were very unfavorable as regards voltage regulation and control of power factor, requiring rearrangement of tap connections to change the ratio from 22,000/66,000 to 22,000/60,000 volts, this arrangement resulting in operating conditions illustrated by curve *B*, when energy is received at L Street Station or at South Framingham, station 24. This condition may be improved by the addition of taps to the high-voltage winding of transformers at L street station or at Baker Street station, the former location for the change being preferable.

To make changes in tap connections rapidly, some special operating mechanism will be required other than what is now available. Such apparatus should preferably be designed for remote control operation. Under present conditions a change in tap connections requires about eight hours and involves a considerable expense. Other methods of accomplishing the same end might include the use of induction regulators or synchronous condensers if the results accomplished would justify their use. It will be obvious that the use of either form of equipment will make it possible to materially improve curves *A* and *B* under any loading conditions, such improvement being of considerable advantage.

Like all transmission companies serving an extended area, the N. E. P. Co. in the past has had to contend with wide variations in voltage in the remote parts of its system, these in part being due to insufficient line capacity and to the effect of loads of low power factor. During the past two or three years these conditions have been materially improved by the reconstruction of certain lines and the installation of a number of synchronous condensers of large capacity at strategic points in the system where control of voltage regulation would be particularly effective. In the operation of the three systems as interconnected, no special provisions have had to be made for voltage regulation other than to provide lines of suitable capacity and suitable tap connections on step-up transformers in the tie lines to secure delivery voltages suited to loading requirements. In the case of the N. E. P. Company's connection, regulation of voltage may be accomplished to a limited extent by increasing or decreasing the number of cables and transformers in service.

The successful operation of interconnected systems appears to require only the complete cooperation of load dispatchers in control of system operation. Modification of existing methods will frequently be found effective in eliminating troubles which occur and in general a careful study of any disturbing factors will usually suggest means for relief in one form or another.

Some Transmission Line Tests

BY W. W. LEWIS

General Electric Company, Schenectady, N. Y.

IN THE MONTH of October, 1919, Mr. J. H. Foote of the Consumers Power Co., and the writer made a series of tests on the 30-cycle 140,000-volt system of that company in western Michigan. A summary of the tests for corona loss has been published.[1] There are some interesting features of these tests which were not mentioned in the previous paper, as their explanation was not clear at that time. The questions in regard to these features have now been pretty well cleared up and they will be discussed briefly in this paper.

Corona loss tests were made on a transmission line 101.5 miles long extending from Junction Dam to Grand Rapids, and some tests with an additional 47.3 miles extending from Grand Rapids to Kalamazoo. Fig. 1 shows a diagram of the system. Power for the tests was supplied by the three 6,250-kv-a., 18-pole,

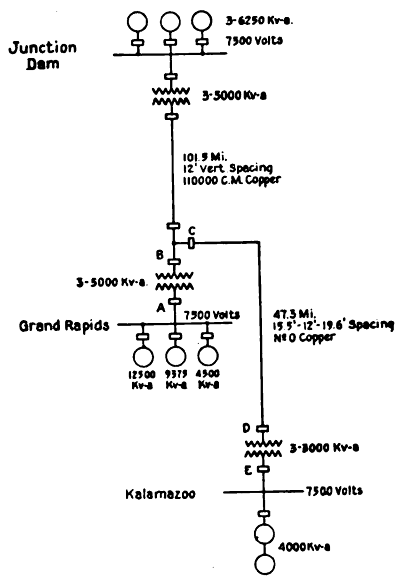

FIG. 1—DIAGRAM OF CONSUMERS POWER CO., 140,000-VOLT 30-CYCLE SYSTEM

100-rev. per min., 7,500-volt, 30-cycle waterwheel-driven generators at Junction Dam. The generators at Grand Rapids and the frequency-changer set at Kalamazoo were not in circuit, switches marked *A* and *E* being open throughout the test.

The line from Junction to Grand Rapids consists of three conductors, each of seven strands medium hard-drawn copper, total cross-section 110,000 cir. mils. The conductors are spaced practically in a vertical plane 12 ft. apart, and supported by 10-disk insulator units in suspension and 12 in strain. The height of lowest conductor at the tower is about 40 ft. and at the middle of the span about 26 ft. The tower spacing averages about 530 ft. The average elevation of the line is about 750 ft. above sea level. The direction of the line is nearly straight north and south with Junction generating station at the north end. There is one transposition tower about every 15 miles giving a complete barrel in about 45 miles. The line had been in service about one and one-half years at the time of the tests.

The line from Grand Rapids to Kalamazoo consists of No. 0 stranded copper conductor spaced 15.5, 12 and 19.6 ft. respectively, with two conductors supported on the top crossarm on opposite sides of the towers and one conductor on the middle arm of a two-circuit tower. The conductor are supported by 10-disk insulator units.

The most important tests were made on the Junction—Grand Rapids Line. The constants of this line are as follows:

Geometrical mean spacing, 181.5 inches.

Radius conductor, 0.19 inch.

Measured resistance per mile at 47.4 deg. fahr., 0.485 ohms.

Measured reactance per mile at 30 cycles, 0.409 ohms.

Measured impedance per mile at 30 cycles, 0.6345 ohms.

Calculated capacitance per mile, 0.01303 $\times 10^{-6}$ farad.

Calculated susceptance per mile at 30 cycles, 2.457 $\times$ 10^{-6} mho.

For the 101.5 miles from Junction Dam to Grand Rapids these constants become as follows:

Resistance, 49.2 ohms.

Reactance, 41.5 ohms.

Impedance, 64.4 ohms.

Capacitance, 1.322 $\times$ 10^{-6} farad.

Susceptance, 249.2 $\times$ 10^{-6} mho.

The step-up transformers at Junction and step-down transformers at Grand Rapids are similarly rated as follows: Three single-phase, water-cooled, 30-cycle, 5000-kv-a., 140,000/135,000/130,000/125,000/120,000-volt high-tension, 7500-volt low-tension, normally connected delta-delta. The tested impedance of the three transformers at Grand Rapids, based on 5000 kv-a., 7500 volts, 30 cycles and measured by applying voltage to the low-tension winding and short-circuiting the high-tension winding, averaged as follows:

7.13 per cent for the 140,000-volt winding
7.22 per cent " " 135,000 " "
7.25 per cent " " 130,000 " "
7.42 per cent " " 125,000 " "
7.55 per cent " " 120,000 " "
Average temperature 25 deg. cent.

1. *General Electric Review*, May, 1920.

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., June 21-24, 1921.

The resistance at 25 deg. cent by shop tests was 17.42 ohms for the 140-kv. winding and 0.0516 ohms for the 7500-volt winding. Excitation curves were taken on the transformers at Junction connected three-

phase, with the results shown in Table I and in Fig. 2. Fig. 3 is an oscillogram of the current and potential waves during the excitation test.

The instruments used in most of the tests were calibrated portable voltmeters, ammeters and wattmeters and calibrated potential transformers and current transformers from the Schenectady Laboratory. In some of the tests the 400:5 ampere calibrated current transformers were not of sufficient capacity so that it was necessary to use the 2000:5 ampere station current transformers. In these cases the station po-

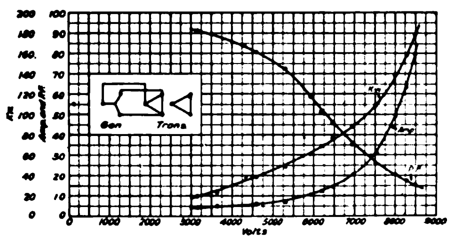

Fig. 2—Excitation Test on Bank of Three 5000-kv-a. 7500 to 140,000-Volt Transformers at Junction—Test 6

tential transformers were also used for convenience. Fig. 4 shows the connections of the instruments for the tests, the power transformers being connected at times delta-delta, and at times delta-Y as shown in the figure.

Delta Connection of Transformers

A portion of these tests was made with the line connected from Junction to Kalamazoo, and the remainder with the line from Junction to Grand Rapids (see Fig. 1). The calibrated current and potential transformers and instruments were used throughout and connected as shown in Fig. 4. In these tests, of course, the high-tension side of the power transformers was connected in delta.

The tests may be described as follows:

October 14-15, 1919:

Test No. 7. Line Junction to Kalamazoo. No transformers at Grand Rapids or Kalamazoo.

Test No. 8. Line Junction to Kalamazoo. Transformers on at Grand Rapids and Kalamazoo.

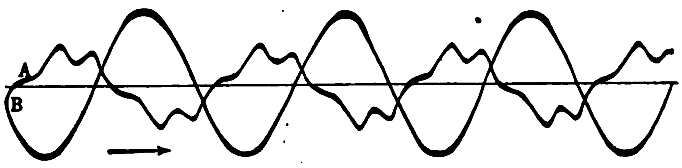

Fig. 3—Low-Voltage Current and Potential Waves During Excitation Test on Transformer Bank—Test 6

See. Fig. 8.

and October before the tests and in November after the tests, average voltmeter, ammeter and wattmeter constants, combining both the instrument and instrument transformer corrections, were evolved. The wattmeter readings were corrected for phase angle in the following manner: The phase angles for the current transformers and potential transformers were obtained from the calibration curves, and a constant phase angle of three minutes assumed for the wattmeter. The apparent power factor was found from the kw. and kv-a. as given by the corrected instrument readings, and the angle θ_2 was found from this power factor. The total phase angle for the instrument transformers and wattmeters was added to θ_2 to give the true angle θ.

The cosine of θ gives the true power factor. The ratio $\cos\theta / \cos\theta_2$ is the correction factor by which the apparent kilowatts are multiplied to give the true kilowatts. This correction factor is greater than one for leading currents and less than one for lagging

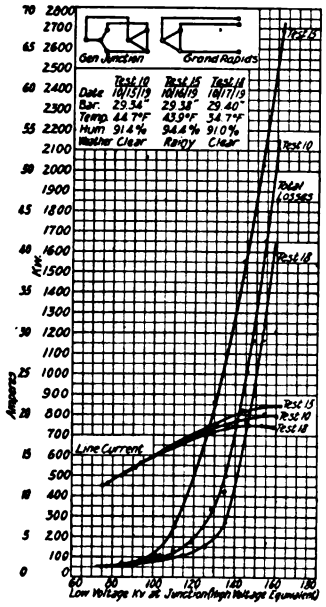

FIG. 5—CORONA LOSS, TESTS 10, 15 AND 18—LINE FROM JUNCTION TO GRAND RAPIDS—NO TRANSFORMERS AT GRAND RAPIDS

currents. The correction factor varies from 5 to 13 per cent at the lower values and from 0.2 to 2 per cent at the higher values. It must be understood that in any event the corrections are approximate. The

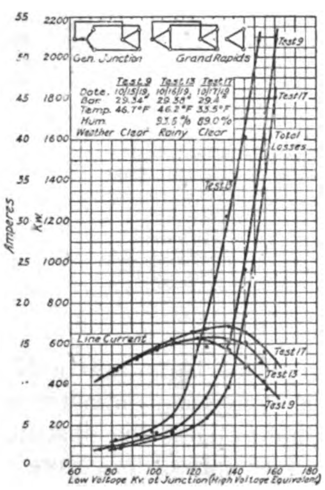

FIG. 6—CORONA LOSS, TESTS 9, 13 AND 17—LINE FROM JUNCTION TO GRAND RAPIDS—TRANSFORMERS ON AT GRAND RAPIDS

values of kilowatts and power factor given in the tables are corrected values found by this method.

Discussion of Results. Fig. 6 gives a comparison of the losses on the line from Junction to Grand Rapids, with transformers connected at Grand Rapids, under clear and rainy conditions and under clear conditions

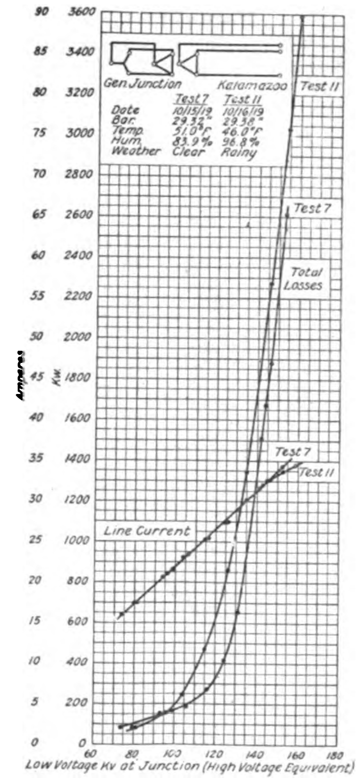

FIG. 7—CORONA LOSS, TESTS 7 AND 11—LINE FROM JUNCTION TO KALAMAZOO—NO TRANSFORMERS ON AT GRAND RAPIDS OR KALAMAZOO

with two degrees of temperature. The effect of increase of temperature and of rain in increasing the

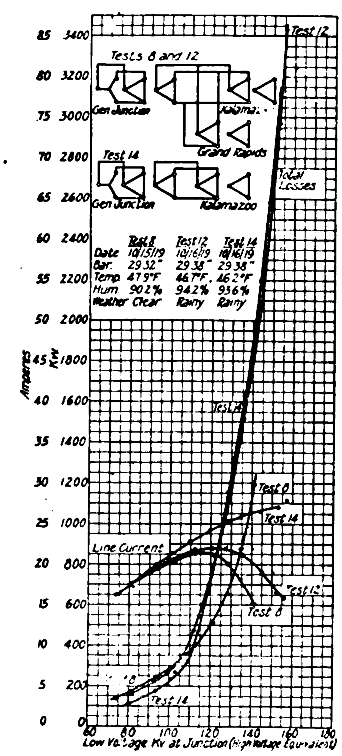

FIG. 8—CORONA LOSS, TESTS 8, 12 AND 14—LINE FROM JUNCTION TO KALAMAZOO—TESTS 8 AND 12, TRANSFORMERS ON AT GRAND RAPIDS AND KALAMAZOO—TEST 14, TRANSFORMERS ON AT KALAMAZOO ONLY

losses is well illustrated. The curves also show the effect of exciting current of the transformers at Grand Rapids, at the higher densities, in decreasing the line current at Junction.

Fig. 5 shows similar curves on the Junction-Grand Rapids line with the transformers at Grand Rapids not connected to the line. The loss curves, it will be noted, practically coincide with those of Fig. 6 except at the lower end, where the loss is nearly all

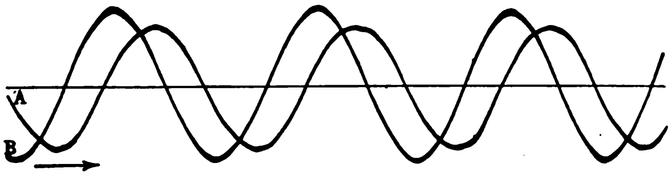

Fig. 9—Low-Voltage Current and Potential Waves Taken During Test 7

Transmission line tests at Junction Dam, Mich.

Corona test at 135 kv., line, Junction to Kalamazoo.
No transformer on at Grand Rapids or Kalamazoo.
Curve A—Line current, low-voltage side.
Curve B—Potential, low-voltage side.

due to the transformers. The line current does not have the marked tendency to droop apparent in Fig. 6, owing to the abscence of the Grand Rapids transformer bank.

Figs. 7 and 8 show curves of losses of the line from Junction to Kalamazoo, the former with no transformers on at the end and the latter with transformers connected.

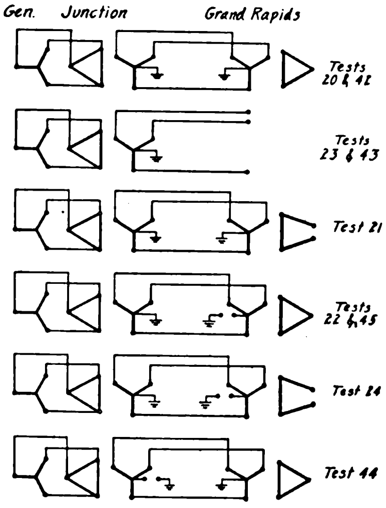

Fig. 10—Diagram of Connections of Power Transformers During Corona Tests with High-Tension Side of Transformers Y-Connected

The loss curves of Tests Nos. 12 and 14 are practically identical, except at the lower portion, where the additional loss of the transformers at Grand Rapids in Test No. 12 raises the curve above that of Test No. 14. The effect of the transformers is also seen in the line current curves.

An oscillogram of typical low-tension waves taken during these tests is reproduced in Fig. 9.

Y-Connection of Transformers

The Y-connected tests were made with the Junction-Grand Rapids line only. In some tests the transformer bank at Grand Rapids was connected to the circuit and in some cases omitted. In all cases the neutral either at Junction or Grand Rapids, and sometimes both, was grounded.

The following tests were made:

October 19, 1919:

Test No. 20. Line Junction to Grand Rapids. Grand Rapids transformers on. Neutrals grounded at Junction and Grand Rapids.

Test No. 21. Low-voltage delta open at Grand Rapids.

Test No. 22. Low-voltage delta closed at Grand Rapids. Neutral isolated at Grand Rapids.

Test No. 23. Grand Rapids transformers disconnected from line.

Test No. 24. Grand Rapids transformers on. Delta open and neutral isolated at Grand Rapids.

October 26, 1919:

Test No. 42. Line Junction to Grand Rapids. Grand Rapids transformers on. Neutrals grounded at Junction and Grand Rapids.

Test No. 43. Grand Rapids transformers disconnected from line.

Test No. 44. Grand Rapids transformers on. Neutral grounded at Grand Rapids. Neutral isolated at Junction.

Test No. 45. Grand Rapids transformers on. Neutral grounded at Junction. Neutral isolated at Grand Rapids.

The various connections are illustrated in Fig. 10, and the results of the tests are given in Tables XIII to XXI inclusive.

Although we have calibration curves for the various instruments we do not have such curves for the station potential and current transformers. It was

thought best, therefore, to give the readings uncorrected rather than to correct for the instruments only. In general the instrument corrections and instrument transformer ratios tend to reduce the readings while the phase angle corrections of the instrument transformers tend to increase them. In respect to current and potential therefore the results may be somewhat high while in respect to watts they are probably somewhat low. The corrections are not large, except at the lower readings where they are sometimes appreciable.

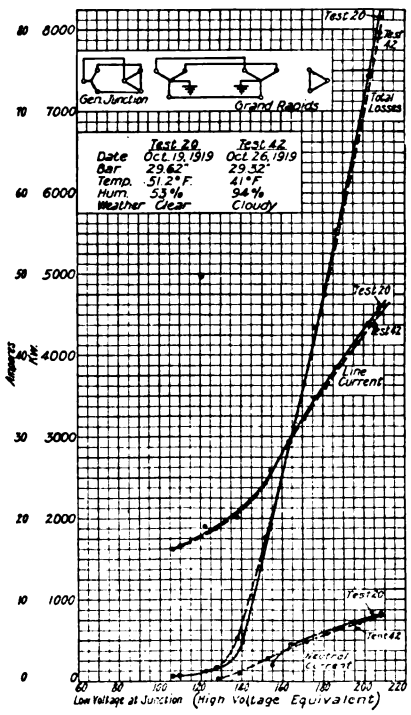

Fig. 12—Corona Loss, Tests 20 and 42—Line From Junction to Grand Rapids—Transformers on at Grand Rapids—Neutral Grounded at Grand Rapids and Junction

Corona loss, amperes line and amperes neutral for Tests 23 and 43 are plotted in Fig. 11 and for Tests 20 and 42 in Fig. 12. The results for the other tests are not plotted, but they follow very closely the plotted curves. In Fig. 13 is plotted the power factor for Test 20, also a comparison of the potentials at Junction and Grand Rapids.

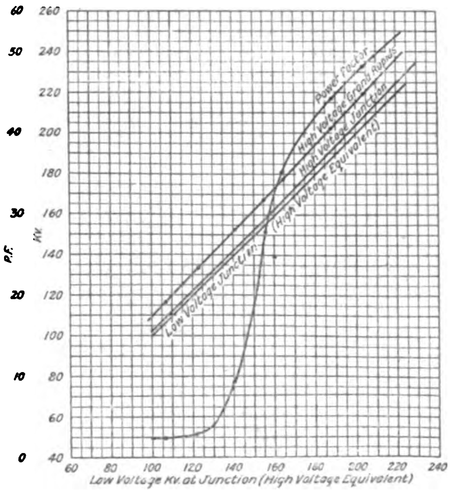

Fig. 13—Comparison of Potentials at Junction and Grand Rapids, Test 20

Discussion of Results. In these tests an ammeter was placed in the neutral ground, or if the neutral was open a voltmeter was placed between the neutral and ground. In some cases it was necessary to use a current transformer in the neutral ground and in some cases the current was read directly. In measuring the neutral voltage a potential transformer was used in all cases.

Figs. 14 and 15 show low-voltage waves of potential and current and high-voltage waves of ground current for Tests 23 and 20 respectively. Fig. 16 shows the potential between neutral and ground for Test 44. The oscillograms show that both the neutral voltage and current are of triple frequency. There are two explanations for this, one advanced by the writer and one by Mr. F. W. Peek. The writer's explanation is as follows:

In the low-tension delta of the transformer bank there is a triple-frequency circulating current which is required by the magnetization of the iron of the transformers. This current is forced through the impedance of the windings by a small voltage which multiplied by the ratio, is reproduced in the high-voltage windings. This voltage impressed between conductors and ground charges the capacitance of the transmission conductors to ground, the charging current of the three conductors in multiple flowing back through the grounded neutral. The action is much the same as for a Y-Y transformer bank with grounded neutral, except that the voltage involved is much smaller.

Mr. Peek ascribed this triple-frequency ground current to the corona, the theory being as follows:

The corona starts at a point well up on the ascending part of the voltage wave, and disappears when the wave has passed through a maximum and reached the same value on the descending portion. This occurs every half-cycle and has the effect of placing a pulsation or harmonic in the voltage wave. The pulsation may be of any odd frequency depending on the point at which the corona starts. Naturally the third harmonic being the first harmonic encountered and being in phase in all three legs, is the most conspicuous. This triple-frequency voltage, acting on the capacitance of the system, which itself is pulsating on account of the increase and decrease of diameter of the conductor due to corona, causes a triple-frequency charging current to flow through the capacitance to ground and back through the grounded neutral.

Mr. Peek has made some laboratory tests, which show conclusively that the greater part of this ground current is due to corona, in accordance with his theory, and that only a small portion of it may be ascribed to the triple-frequency magnetization of the transformers, as suggested by the writer. This greatly relieves the situation as it places the onus for this ground current on the corona, which may be avoided and not on the transformer magnetization which is unavoidable. Mr. Peek will describe his theory and tests in detail in a paper at this meeting.

The tests show that with open line and one neutral grounded the ground current is from 20 per cent to 40 per cent of the line current at corresponding voltage. With neutral grounded at both ends (and low-tension deltas closed) the neutral current at each end is from 10 per cent to 20 per cent of the line current, the current splitting in this case between the two ends. With transformers at both ends of the line but neutral grounded at one end only (Test 22), or with transformers at both ends of the line and both neutrals grounded, but the delta open at the receiving end (Test 21), the neutral current at the generating station is practically the same as when the line is open at one end.

With transformers at both ends and the neutral at one end only grounded, a voltage exists between the isolated neutral and ground as shown in Fig. 16.

It will be noted that the neutral current begins abruptly in the neighborhood of 140 kv., which means that at lower voltage the current was so small as to give no indication on the ammeter. Thus with the transmission line operating at normal voltage, the ground current will be negligible, and no trouble should be experienced from it.

Rise in Voltage. The power factor in the tests varies from 2 to 50 per cent leading. We would naturally expect a boost in voltage, due to this leading current passing through the reactance of the transformers and transmission line. Fig. 13 shows the voltage rise along the line for Test 20. The rise through the transformers was calculated. The voltage at the Grand Rapids end of the line was measured on the low-tension side, and the high-tension voltage is this measured voltage multiplied by the ratio, as there is no current passing through the transformers and therefore no change in voltage. The calculated rise in voltage along the line is considerably less than the measured rise.

The tests with open line (Grand Rapids transformers connected), Tests Nos. 23 and 43, should give

a greater rise than the tests with transformers at the end of the line. The calculated rise with open line, however, is much less than measured with transformers at the end of the line.

These discrepancies may be caused by change in capacitance due to corona, or by harmonics introduced by corona, which will be discussed later.

Open Delta. In Test No. 21 the transformers were on at Grand Rapids, with neutrals grounded at Junction and Grand Rapids. The low-tension delta was open at Grand Rapids. A voltmeter placed across the corner of the open delta read about 600 volts with 203 kv. at Junction.

In Test No. 24, in addition to having the low-tension delta open, the high-voltage neutral was isolated at Grand Rapids. Now a voltage was read

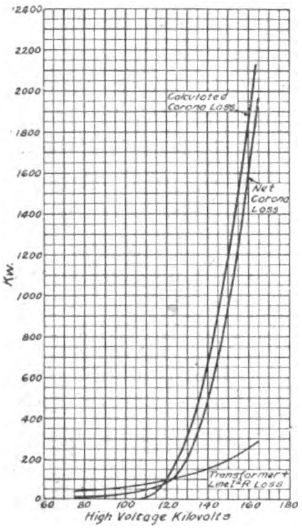

FIG. 17—COMPARISON OF CALCULATED AND MEASURED LOSSES, TEST 10

across the corner of the open delta which amounted to 13,500 volts with 203 kv. at Junction. One-third of this appears across each leg of the low tension. The triple-frequency leg voltage multiplied by the ratio of transformation gives the triple-frequency voltage across each leg of the high tension, and this voltage (75,000 in this case) appears between the neutral and ground. Such voltages may be expected with Y-Y connection without tertiary winding, and it will be noted that they rise to very high values.

COMPARISON OF CALCULATED AND TEST CORONA LOSSES

It is very difficult to get the true loss, either tested or calculated. The test loss must necessarily be taken on the low-tension side and is subject to correction for the transformer core loss and i^2r loss and the transmission line i^2r loss. Phase angle corrections of instrument transformers change the results. On account of the rise in voltage over the line, it is doubtful to what voltage the loss should be referred. On the other hand, in calculating the loss, there are certain assumptions to be made as to the irregularity factor, the spacing of conductors, etc. Corona loss starts first on the middle conductor and this is not taken into account in figuring e_0 with the geometrical mean spacing.

Nevertheless the tests here recorded are believed to be fairly accurate and the results representative of the actual corona loss. Also the calculated losses represent the losses accurately within the limitations of the formulas for a line which fulfills the assumed conditions.

See Fig. 17.

In Fig. 17 is given a comparison between the tested and calculated corona losses for Test No. 10. In these and the following calculations m_0 is assumed as 0.85 and m_v as 0.82. The test readings were corrected for instrument and instrument transformer errors, and from the total losses thus found are substracted the transformer core and i^2r loss and the line i^2r loss (see Table XXII). The high-tension voltage is calculated from the low-tension voltage and the constants of the transformers, and this voltage is considered uniform throughout the line. The corona losses are calculated and plotted against this high tension voltage. The calculated losses are higher than the test losses except at the lower part of the curve. Calculated e_0 is 108.1 while the test e_0 is about 120 kv. Calculated e_v is 148.5 kv.

In Fig. 18 are given comparisons of calculated and test losses for Tests 15 and 18. In this case the test losses given are the total losses, including transformer

losses and line i^2r. The voltage is the low-tension voltage times the ratio, uncorrected for rise through the transformer. The comparison here is useful mainly in showing the shape of the curves. The calculated e_0 for Test 15 is 86.6 kv. based on storm $e_0 = 0.8$ fair weather e_0. This is apparently too low a value. It may be that the rain was not sufficient to give such a lowering of e_0, although reports showed that there

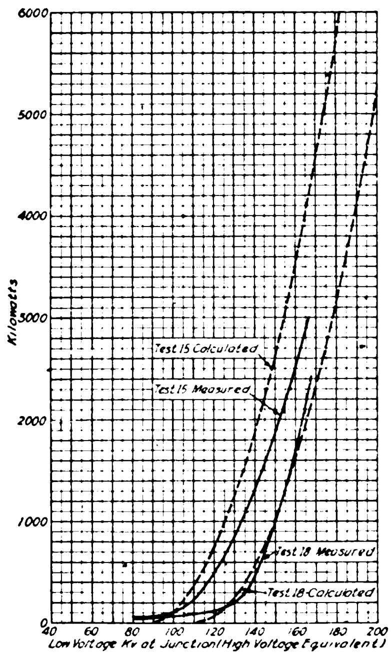

FIG. 18—COMPARISON OF CALCULATED AND MEASURED LOSSES, TESTS 15 AND 18

was a gentle drizzle at the two ends of the line and at Croton, part way along the line. The calculated e_v for Test 15 is 148.8 kv. For Test 18 the calculated e_0 is 110.4 and e_v 151.1 kv.

Fig. 19 gives a comparison of tested and calculated losses for Test 20. The test loss is the total loss less the transformer loss and line i^2r loss, (see Table XXIII). The calculated loss is plotted for the average of the high-tension voltages at Junction and Grand Rapids. Calculated e_0 is 107.5 kv., and e_v 148.6 kv.

In Fig. 20 are plotted the net corona loss (that is total test loss minus transformer loss at both ends of

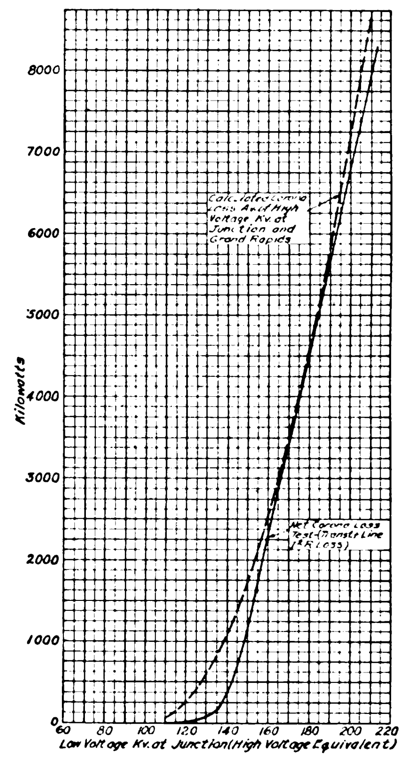

FIG. 19—COMPARISON OF CALCULATED AND MEASURED LOSSES, TEST 20

line and line i^2r loss) and the calculated corona loss for Test 42, (see Table XXIV). The losses are plotted against the average of the high-tension voltages at the two ends of the line as found by test. The calculated e_0 in this case is 108.9 and e_v is 149.3 kv.

The test readings of Tests 20 and 42 are subject

See Fig. 20

to correction for instrument and instrument transformer errors, which would probably increase the values of kilowatts at the low points.

It is evident from a comparison of the test and calculated curves shown on Fig. 17 to 20 inclusive that

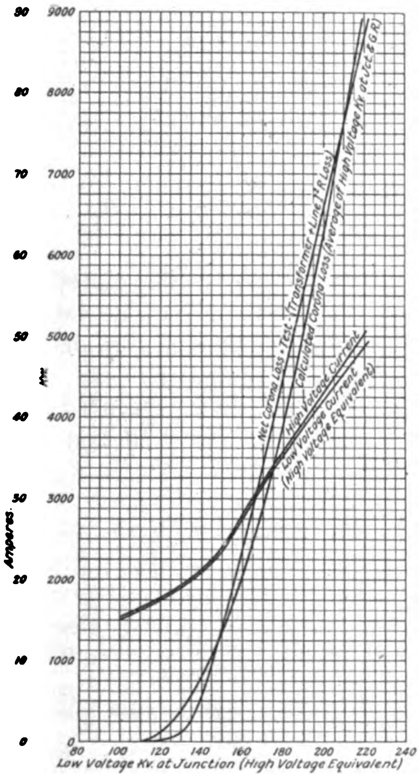

FIG. 20—COMPARISON OF CALCUALTED AND MEASURED LOSSES, TEST 42

while these curves are in general very much alike in shape and magnitude, still there are some marked discrepancies, and at the lower part of the curve in particular there are noticeable deviations. The test curves in all cases give a lower loss and have a more abrupt bend than the calculated curves. Peek explains this by saying that below e_v the quadratic law does not hold, that the loss here is due to irregularities and that the probability law governs. The probability law is stated:

$$P_1 = q^{-h\,(e_v - e)^2}$$

in which q is a coefficient depending on the number of spots and h is a coefficient depending on the size of the spots. This loss, therefore, depends on two coefficients whose value it is difficult to approximate.

Peek further states that it is of practical importance only to know the limits of the loss on this part of the curve and that e_0 should generally be the limit of the voltage on practical lines, as otherwise storm losses become excessive. This is very well taken and we have no doubt that Peek has stated the case correctly. The desirability of operating below e_0 is more evident than ever in view of the ground current described in this paper.

Nevertheless a large number of systems are operating between e_0 and e_v and in figuring on new systems or extensions to old systems, it is frequently an economical problem whether to go to a larger size conductor or to stand a limited amount of corona loss. In these cases it is desirable to be able to calculate approximately the losses between e_0 and e_v, and to know whether the actual losses will be higher or lower than the calculated losses.

It is doubtful whether the present data are sufficient or of enough accuracy to use in checking the corona law, but it would seem desirable that the law be checked by actual line tests to determine whether or not there is any regularity or uniformity below e_v or whether the deduction of any general law is hopeless, as intimated by Peek.

CHANGE IN CAPACITANCE

Some discrepancies were noted in these tests between the calculated charging current and the tested charging current of the line, between the calculated

voltage increase along the line and the measured voltage rise, also between the calculated ground current and the measured ground current. These quantities may be brought closer together by assuming that the corona which breaks down the air surrounding the

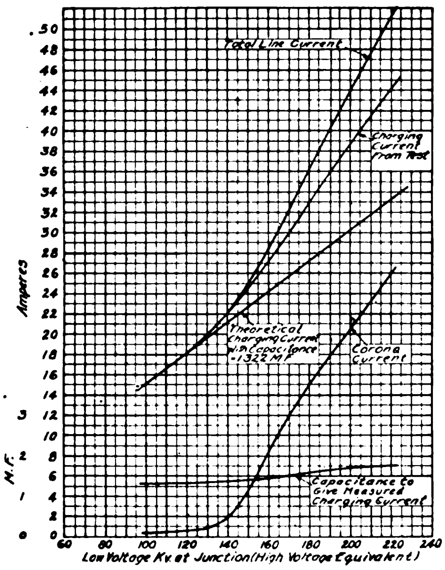

FIG. 21—COMPARISON OF CALCULATED AND MEASURED CHARGING CURRENT, TEST 20

conductor and makes it conducting has the effect of increasing the diameter of the conductor, thereby increasing the capacitance and decreasing the inductance from the calculated values. Also the harmonics placed in the voltage by the corona would naturally increase the charging current and the rise in voltage along the line.

100	105.8	15.2	16.2	1.406
110	116.1	16.7	16.6	1.313
120	126.5	18.2	18.3	1.33
130	136.9	19.7	20.2	1.356
140	147.3	21.2	21.8	1.36
150	157.8	22.7	24.3	1.415
160	168.2	24.2	26.6	1.452
170	178.7	25.7	29.6	1.522
180	189.2	27.2	32.9	1.598
190	199.6	28.7	35.7	1.642
200	210.1	30.4	38.5	1.685
210	220.7	31.7	41.5	1.728
220	231.1	33.3	44.3	1.76

See Fig. 21.

In Fig. 21 (see table XXV) the total high-tension current of Test No. 20 is plotted, also the power and reactive components, the former being due to the corona loss and the latter being the charging current. The theoretical charging current with constant capacitance of 1.322 microfarads to neutral is also plotted. It will be seen that there is a constantly increasing deviation between the calculated and tested charging currents. The values of capacitance which would give the tested charging current are plotted and it will be noted that they begin at 1.322 microfarads and increase with increasing voltage.

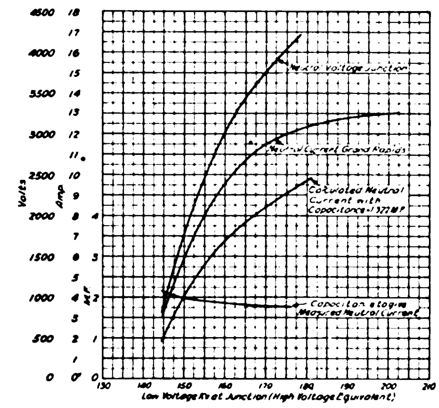

FIG. 22—COMPARISON OF CALCULATED AND MEASURED CURRENT IN GROUNDED NEUTRAL, TEST 44

On Fig. 22 are plotted the neutral ground current measured at Grand Rapids in Test 44, the neutral voltage at Junction and the calculated neutral ground current found from the neutral voltage and the theoretical capacitance of 1.322 microfarads from conductor to neutral, (see Table XXVI). The test values are greater than the calculated and tend to become increasingly greater at the higher voltages. There are also plotted the values of capacitance which would give the measured charging current. These are greater than 1.322 microfarads but appear to decrease with increasing voltage. This is not consistent with the preceding paragraph, in which the capacitance is found to increase with increasing voltage. If we assume that not all the neutral current is capacitance current, but part of it is true power, or corona current, then we can arrive at a reasonable capacitance curve. We, however, introduce a new element into corona loss, namely a triple-frequency component.

TABLE XXVI

COMPARISON OF MEASURED AND CALCULATED NEUTRAL CURRENT

TEST NO. 44

L. V. Kv. Junction (H. V. Equiv.)	Volts Neut. to Ground	Calc. neut. current $C = 1.322$ microfarads	Test neut. current chg.	Capacity to give test neut. current microfarads
145	900	2.02	3.25	2.128
150	1800	4.04	6.0	1.963
155	2475	5.55	8.0	1.903
160	3000	6.73	9.6	1.884
165	3425	7.68	10.75	1.849
170	3750	8.42	11.5	1.806
175	4030	9.04	12.0	1.754

See Fig. 22.

The actual rise in voltage over the line is apparently greater than the calculated rise, for example the tested rise in Test No. 42 at 180 kv.(equivalent high voltage) is 4300 volts or 2.34 per cent, while the calculated rise is only 600 volts or 0.33 per cent.

The above calculations are based on a capacitance of 1.322×10^{-6} farad and a reactance of 41.5 ohms for the 101.5-mile line, which are the calculated values for the particular size and spacing of conductor. Now if the radius of the conductor is increased to give increased capacitance as shown on Figs. 21 and 22, most of the calculated results show a much closer agreement to the tests. From this it appears that the radius of the conductor increases with the corona, perhaps being a function of the excess of the applied voltage over the critical corona voltage. The rise in voltage along the line is only partly accounted for in this manner, and harmonics may play a controlling part here.

Conclusions

Corona losses at approximately 210 kv. at the generating end and 225 kv. at the receiving end of a 100-mile line of 110,000-cir. mil conductor have been recorded.

The losses in general follow Peek's law, with some deviation especially at the lower voltages, where the tested loss is as a rule less than the calculated.

A current in the grounded neutral was encountered which at the higher voltages was about 40 per cent of the line current. This current begins at about the normal line voltage. It is apparently due to the corona, which causes a pulsation in the voltage wave and a triple-frequency current to flow through the capacitance to ground and back through the grounded neutral.

The line charging current, the current in grounded neutral and the rise in voltage along the line are all greater than calculated from the geometrical capacitance. This may be accounted for by an increased capacitance due to increased diameter of conductor caused by corona. Harmonics introduced into the voltage wave by the corona may contribute to the effect noticed.

The tests indicate a difference in corona loss with the neutral grounded and isolated, probably due to the flow of triple-frequency current in one case, and the distortion of voltage by triple-frequency component in the other.

The danger of overvoltage across legs and between neutral and ground with Y-Y connection is shown by Test 24.

The tests clearly indicate the desirability of operating a transmission line below the corona voltage, thus avoiding corona loss and its accompanying effects.

A NEW EXCHANGE BETWEEN FRENCH AND AMERICAN UNIVERSITIES

There has been for some time a regular annual exchange of professors between individual universities in France and America in regular academic fields, but there has never been, as yet, any such exchange in engineering or applied science. These subjects are taught in France under special faculties, not included in existing exchanges with America. Furthermore, the French methods of teaching these subjects are unlike our American methods, for various reasons, based on the history, traditions and sociology of the two countries. The great war showed the importance of engineering in production and distribution, and the many ties of friendship which bind us to France depend, in various ways, upon applied science. It should therefore, be to the mutual advantage of France and America to become better acquainted with each other's ideals and viewpoints, in the study and in the teaching of these great groups of subjects.

With these purposes in mind, the late Dr. R. C. MacLaurin, in 1919, as President of the Massachusetts Institute of Technology, consulted the presidents of six universities on or near the Atlantic seaboard, as to whether they deemed it desirable to cooperate in such a joint exchange of professors with France, on a plan definitely outlined. Their replies being very favorable to the project, a committee was appointed, with one member from each of the seven institutions, to report on the plan, and on methods of carrying it into effect. The committee met in December 1919, and ratified the cooperative plan with some few modifications. The present president of the committee is Director Russell H. Chittenden of Yale, and its secretary Dean J. B. Whitehead of Johns Hopkins.

Since the Institute of International Education in New York concerns itself with the interchange of college students and teachers from all parts of the world, the committee requested the Institute's director, Dr. Stephen P. Duggan, to undertake the negotiations between the committee and the French University Administration. The French have selected, for their first representative, Professor J. Cavalier, rector of the University of Toulouse, and a well-known authority on metallurgical chemistry, to come to America this fall, and to divide his time during the ensuing academic year among the seven cooperating institutions, namely, Columbia, Cornell, Harvard, Johns Hopkins, Massachusetts Institute of Technology, Pennsylvania and Yale.

The American universities have selected as their outgoing representative for the same first year (1921-22), Dr. A. E. Kennelly, professor of electrical engineering at Harvard University and the Massachusetts Institute of Technology.

Long-Distance Transmission of Electric Energy

BY L. E. IMLAY

of the Superpower Survey, New York, N. Y.

The paper discusses long-distance transmission of electric energy dealing with (1) the economic conditions which justify it, (2) the plant involved, and (3) the service that may be expected.

The economic conditions which justify long-distance transmission of electric energy are a cheap source of power with an insufficient local demand to absorb it, and a distant market to which the energy can be delivered cheaper than energy con be supplied at that point from any other source.

In dealing with the plant required for long-distance transmission some of the considerations that affect the design are discussed. A graphic method of determining line performance is illustrated by an example and some essential data on other lines are given. Among the important physical considerations entering into transmission line design, right of way, spacing of towers, line insulators, high-tension switches and lightning arresters are discussed.

Service is considered from the viewpoints of, what people demand, what perfect service will cost, and the service that may be expected from a large interconnected system consisting of steam plants at the mines, hydro plants wherever available and local steam plants.

IT IS PROPOSED in this paper to discuss long-distance transmission of electric energy from three standpoints. First, from the economic point of view, by consideration of the conditions which justify long-distance transmission. Second, from the physical viewpoint, by dealing with the design, construction, and operation of long-distance lines. Third, from the point of view of service, by consideration of the factors, contributing to continuity of service and its value to the people served. This discussion is to some extent based on studies which have recently been made in the development of a superpower system, for the industrial district along the Atlantic Seaboard.

THE ECONOMIC JUSTIFICATION FOR LONG-DISTANCE TRANSMISSION

The laws governing the distribution of electric energy under ordinary conditions, losses involved and the various items entering into distribution costs, are fairly well-known. However, when large amounts of electric energy are to be transmitted over long distances the problem is greatly complicated by factors which do not appear, or are negligible in the ordinary distribution of energy. In every power transmission problem the question to be answered is: Can energy be generated and transmitted to the point where it is needed more cheaply than it can be generated at the point of demand?

The two available sources of power at the present time are expansive force of steam and the energy of water acting from force of gravity. In addition to these we have various forms of chemical energy, energy from internal combustion engines, the mercury vapor engine, energy from the winds and tides and heat energy from the sun, but the application of these as prime movers to the generation of millions of kw-hr. for general distribution appears to be remote.

The point at which energy can be developed by water power is located for us by nature and we must make what we can of it. A power plant located at a waterfall is rarely in an industrial community or where an industrial community may be developed. There are exceptions to this as at Niagara Falls, but in general waterfalls are in out of the way places and their use for power development must either await a local demand, after factories or electrochemical works are built, or the energy must be transmitted to already developed communities where there is demand for it. The problem is whether it will pay to develop it at all, and if this is answered in affirmative whether it will pay better to use the energy nearby or to transmit it to a distant market.

Electric energy by whatever source of power it may be generated should be used in such manner as to supply the economic needs of the country at maximum efficiency. This in general means that hydroelectric energy generated at waterfalls away from centers of industry and steam-electric energy generated at the coal mines must be transmitted to distant centers of demand in order to find a market; but if a demand should exist near the place where the power is generated then that demand must be supplied first, and only the residue, if any, transmitted to the more distant point. This statement should be qualified by the proviso that the local demand for energy be such that the economic needs of the country be supplied by that means more cheaply than in any other way. For example, energy generated by water power at Niagara Falls should be used at that point for the manufacture of chemicals needed by all the people of the country and which can be manufactured and marketed from there more cheaply than anywhere else, rather than sent to New York with the attendant losses and cost of transmission. Niagara Falls energy should not be used locally for heating dwelling houses and factories, even if the producers could furnish it for this purpose, at a profit to themselves, as houses can be heated more economically in some other way. If such use were the only local means of absorbing Niagara energy, then such energy should be sent to a more distant market where it would serve a better purpose. Furthermore, Niagara energy should not be sent to more distant points so long as

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

there is a demand for it in Buffalo, or nearby cities. If, however, hydroelectric energy can be developed at Niagara Falls faster than it can be absorbed in the surrounding territory, it would be in order to build transmission lines to convey the excess energy even as far as New York provided it can be sold at a price which would permit the amortization of the transmission plant while the local demand is being built up. Thus if governmental permission could be obtained to divert water from the Niagara River for generation of 600,000 kw. it is quite within economic possibility that a block of 300,000 kw. could be transmitted to New York and sold at a price which would net a profit to the promoters and provide an adequate sinking fund to retire the investment in transmission equipment. The reason such expenditure can be justified is that energy in bulk is worth about three times as much in New York as it is worth in Niagara Falls.

There are many places where electric energy may be generated from water power where there is locally no present or prospective demand for it. Such locations in the eastern states where large amounts of undeveloped energy may be obtained are the St. Lawrence River, the rivers of the Adirondack Mountains, and the rivers of Maine. The question here is: Can these developments be made and the energy transmitted to any existing, or prospective markets, cheaper than a like amount of energy can be generated at the point where the demand exists, or developed and transmitted to that point from any other source? The competing source of energy will probably be steam-electric energy generated locally or at the mines.

In the case of long-distance transmission of energy from steam plants the same law holds good, that such energy should be used as near the point where it is generated as possible, provided the needs of the country are thereby supplied more cheaply than in any other way. If, for instance, there should be found an economic demand in the anthracite region of Pennsylvania for all the energy that can be generated in that region, due to limitation in supply of condensing water or steam sizes of coal, or to any other cause, then such energy should all be used in the anthracite region. In any case only the residue, after supplying the local needs, should be transmitted to distant centers of demand. The anthracite mines are very deep and require much energy for pumping ventilation and for haulage. In this region it requires 20 kw-hr. of energy to mine and place on the cars one ton of coal. When all the mines are electrified as they probably will be within the next few years, the 80,000,000 tons of coal mined per annum will require 1,600,000,000 kw-hr. of energy at a demand rate of about 400,000 kw. The railroads in the anthracite region will doubtless soon have to be electrified on account of the heavy tonnage and the steep grades. This territory is also developing a large miscellaneous industrial load. It is estimated that approximately 800,000 kw. will be required to supply the total demand for electric energy in this region within the next ten years. All this demand will have to be satisfied, before energy is sent from this region to distant markets.

There are limitations in generating power in the anthracite region due to the amount of condensing water and steam sizes of coal which are available. If, however, highly efficient generating plants are built to supply the 800,000 kw. needed for the local demand, considerable off peak power will be available for transmission to such load centers as New York and Philadelphia. There is also considerable diversity of load between these centers as the peak of the load in the Metropolitan District does not come on until a large part of the load in the anthracite region has gone off.

In the bituminous fields of the Appalachian region the conditions are very different from the conditions in the anthracite field. Very little shaft mining is done and consequently very little energy is needed for pumping water or hoisting. This condition will exist for some years until deep level mining becomes necessary. Eighty per cent of the bituminous mines are already electrified—the principal use of energy being for mine haulage. Therefore, almost all the energy which can be generated at the bituminous mines is available for distant markets.

Unfortunately there are few locations near the mines within reasonable transmission distances of load centers along the Atlantic seaboard where steam plants can be located convenient to coal supply and where there is ample condensing water. Investigation shows that there is no location within 300 miles of New York City where both coal and water can be found for a 100,000-kw. high-efficiency steam plant without the necessity of transporting coal from 10 to 50 miles by railroad. Therefore, quite an appreciable freight charge is involved even for such plants.

The cost of gathering coal from the mines and delivering it to the power plant which must be located where condensing water is available, has a very important bearing on the general problem of transmission of electrical energy from the coal mines. In order to justify the transmission it is necessary to show that the value of the energy lost plus the fixed charges on the cost of the transmission plant is less than the net cost of freight on coal required to generate the same amount of energy at the point of use.

In view of what has been said the economic justification for long-distance transmission of energy may be stated as follows: In the case of all energy generated, either steam-electric or hydroelectric, after the local demand has been satisfied, the residue may be transmitted to distant centers of demand when it can be delivered more cheaply than the energy can be supplied at that point from any other source.

Long-Distance Transmission Lines

It is not the purpose of this paper to show how to design high-tension transmission lines, nor how to calculate the performance of these lines, but to point out some of the considerations that must be taken into account and to give some typical examples of design and line performance that have been worked out.

A transmission line should be capable of transmitting the amount of energy for which it is designed at minimum cost. Kelvin's law may be used in the design of high-tension lines by including in the investment the cost of other apparatus which varies for the different sizes of conductors compared, as for example, towers, insulators, transformers, synchronous condensers, switch equipment, etc., the interest and depreciation on which shall equal the value of the energy lost. The law, however, must be applied with the reservation that corona must not be the limiting factor. The design of long-distance lines differs from the design of ordinary circuits for carrying electric energy in that certain factors must be taken into account that may usually be neglected. Corona, reactance and capacitance are each factors that have to be carefully reckoned with. Each of these characteristics present definite limitations which are susceptible of accurate determination in advance. These same limiting characteristics are useful in the operation of the line and may be regarded as making long-distance transmission of electricity possible.

Corona becomes a serious limitation to long-distance transmission at high voltage. There is a critical disruptive voltage for each size of cable, depending on the spacing and arrangement of conductors, the elevation above sea level and the meteorological condition of the atmosphere. Rain, fog, and particularly falling snow increase the tendency for energy to discharge from the conductors and lowers the critical voltage.

Thus for a particular voltage, elevation and climatic condition, there is a definite lower limit to the size of conductor that can be used irrespective of whether this is the most economical section so far as cost balanced against losses is concerned. It may easily happen in a particular instance that diameter in transmission conductor is more important than conductivity and this may determine the material of which the cable is composed or the manner in which it is made. Increase in diameter may be obtained by using aluminum or copper cable with steel core. Corona, however, has at least one redeeming quality in that it doubtless assists materially in dissipating induced high-frequency charges on the line that otherwise would be destructive to insulation of line, transformers and switches.

Reactance limits the amount of energy that can be transmitted over a given line. It varies with the size, arrangement and spacing of the conductors and the reactance volts vary with the current to be transmitted. With a particular line and a definite amount of energy to be transmitted the reactance voltage drop to be dealt with is decreased by increasing the vo tage. Where reactance is the factor limiting the amount of energy that can be transmitted over a given line the only way to increase the amount of energy that can be transmitted is to increase the voltage. This in turn may be limited by corona unless the diameter of the cable is increased. Increase in size and consequent cost of conductors for a particular transmission has a definite limit depending on the cost of producing energy in some other way at the point of destination. Reactance is useful, in that it limits the current that can flow in case of short circuit. It thus prevents destruction of the windings of transformers from excessive mechanical strains and makes it possible for switches to open the circuit during short circuits by limiting the flow of current to an amount that can be successfully broken.

It may be mentioned here that by an arrangement of divided conductors, two cables being suspended from one insulator a few inches apart and used as a single conductor—the reactance of the line may be greatly reduced and its capacity proportionally increased. This will enable the line to transmit a much greater amount of energy without increasing the synchronous condenser capacity necessary to regulate it, or conversely if the amount of energy is not increased less synchronous condenser capacity will be required. This advantage is obtained without increase in weight of copper and change in resistance of conductors. The following illustrates the effect of thus dividing the conductors:

	Single Conductors	Divided Conductors
Length of line	350 miles	350 miles
Size of conductor.........	(1)—605,000 cir. mils	(2)—302,500 cir. mils
Energy transmitted per circuit..................	150,000 kw.	150,000 kw.
Voltage of transmission....	220 kv.	220 kv.
Losses..................	14,900 kw.	18,180 kw.
Synchronous condenser capacity required at full load.	76,000 kv-a.	40,350 kv-a.

Capacitance determines the charging current of a line, and depends on spacing, diameter and arrangement of the conductors, frequency and length of the circuit. If full voltage is impressed on a transmission line at the generating end and the receiving end of the line is left open the voltage of the receiving end may rise to such a value as to cause serious damage. At the same time the charging current flowing into the line which must be supplied by the generators may be equal to or even greater than the energy current on the line when fully loaded. This may be much in excess of the capacity of one of the largest generators in the generating station. In case of the 350-mile 220-kv. line just mentioned with single conductors the charging current which must be furnished at the generating station with 220 kv. impressed on the line at 60 cycles is nearly 100,000 kv-a. for each three-phase circuit (200,000 for the two circuits in parallel). This is about equal to the current carrying capacity of four 50,000-kw.

(59,000-kv-a. at 85 per cent power factor) generators operating in parallel. In other words, it will require generator capacity necessary to provide 200,000 kv-a. leading current to energize such a two-circuit line designed to transmit 150,000 kw. The charging current being leading in the armature of the generator tends to increase its excitation thus making it self-exciting, possibly to such an extent that it becomes beyond control of the separate field excitation usually provided. In the case cited above, if the frequency were 25 cycles, the charging kv-a. would be about 40,000.

Synchronous condenser or synchronous reactor capacity may be so adjusted to a transmission line as to neutralize lagging or leading current at any point in the line. Capacitance in a line serves much the same purpose as synchronous condenser capacity, the difference being that the former is distributed along the line and cannot be controlled, while condensers are generally located at the receiving end only and can be adjusted to compensate for change in power factor and load. In gradually loading up a line there is a point at which the charging current resulting from capacitance just balances the reactance thus giving unity power factor at the generating end of the line. On a long transmission line it may be found advisable at normal loading to operate with a leading power factor at the generating end of the line which results in unity power factor near the middle of the line and a lagging power factor at the receiving end.

Many factors enter into the choice of voltage for a transmission line. Other conditions being equal, that voltage should be chosen which will permit the energy to be transmitted at minimum cost. The writer knows of one instance where 100,000 kw. was transmitted 2½ miles at 12,000 volts as the price of copper was such that the interest on the investment in copper plus the value of the energy lost in the 12,000-volt circuits was less than the interest on the cost of step-up and step-down transformers, and the other items of cost that the higher voltage would have involved. The economic voltage is dependent upon the amount of energy involved. In the case of very long lines and large amounts of energy the economic voltage is the highest that the state of the art will permit. This at the present time is about 220,000 volts. On shorter lines it may be desirable to adopt a voltage that corresponds to that of other lines in the vicinity in order that the circuit may run in parallel without the introduction of transformers. Determination of the proper voltage for a project requires careful analysis of all the factors bearing on the problem after full knowledge of the value of these factors has been ascertained.

Frequency will generally be determined by the prevailing frequency of the district to be supplied. Up to 350 miles it is practicable to design operative transmission lines for either 60 or 25 cycles, the prevailing frequencies in this country. Beyond this distance it may be found advisable to use the lower frequency in order to keep the reactance and capacitance susceptance within practical limits. There is very good reason to believe that 60 cycles will eventually prevail in this country and all new projects except those involving very long transmission lines should be at this frequency. Even in those communities where 25 cycles now prevail it is usually practicable to take on new business at the higher frequency so that eventually the lower frequency may be retired. In the beginning there was very good reason for the adoption of 25 cycles on account of it being impracticable to build 60-cycle synchronous converters for changing to direct current. Sixty-cycle synchronous converters have now been developed which answer all requirements, and the reason for the lower frequency more expensive apparatus no longer exists.

It is particularly unfortunate that the two prevailing frequencies in this country are such that frequency-changers are necessarily very expensive. There is only one speed, namely 300 rev. per min., which results in a ratio of 25 to 60 cycles. Such machines must have 10 poles for the 25-cycle end and 24 poles for the 60-cycle end, thus necessitating a very expensive machine even for small installations. If 30 cycles had been chosen instead of 25 the matter of changing frequency would have been greatly simplified as the lower frequency machine would then have a pole ratio to the higher of 1 to 2, and in general could be built at much lower cost. This would have been of considerable advantage in the transition of 25-cycle systems in this country to a 60-cycle standard. Or if 50 cycles had been chosen as is generally the case in foreign countries a ratio of 1 to 2 would have also resulted.

The performance of a transmission line may be completely determined graphically with the degree of accuracy necessary for preliminary studies by the use of vector diagrams indicating currents and voltages at the two ends of the circuit and applying the auxiliary constants of the circuit which account for the distribution effect. These constants may be read direct from the Wilkinson Charts. The following illustrations of this graphic method are given as applied to a 225-mile 220-kv., 60 cycle transmission, designed to transmit 300,000 kw. and supply an industrial distributing system at 85 per cent power factor. The transmission will consist of two tower lines, each supporting two circuits; additional line characteristics and load data are given on the diagrams which apply to one 605,000-cir. mil aluminum steel reinforced three-conductor circuit. Under normal conditions each circuit will transmit 75,000 kw. and under emergency conditions will transmit 150,000 kw. The voltage will be held at the high-voltage side of the raising transformers and at the low-voltage side of the lowering transformers. This somewhat simplifies the calculations as it eliminates the impedance of the raising transformers from consideration. In each of these solutions the impedance of the lowering transformers is added to the line im-

pedance and regarded as if it were distributed line impedance. The percentage of error due to this assumption is shown in the lower right-hand corner of each diagram. For an exact determination of the performance of a very long line the complete method of solution would be demanded. In this complete method the localized impedance of the raising and lowering transformers is not considered as distributed line impedance but treated as localized impedance. The illustrations show, in addition to a complete graphical method of solution, the mathematical solution which exactly parallels it. The quantities given on the illustration have been carried out to an extreme degree of refinement so that the error in results as determined by this simplified approximate method compared with the more complicated complete method (not shown here) could be accurately obtained. It may be noted that the approximate solution shown by illustration takes into account the effect of the condenser and lowering transformer losses flowing over the circuit and the effect of the magnetizing current of the lowering transformers in reducing the effective capacity of condenser capacity under load.

Fig. 1 shows the conditions existing at no-load with normal load connections and with line and lowering transformers energized. With 220 kv. at low-voltage side of lowering transformers, synchronous reactor capacity of about 30,000 kv-a. will be required to hold the voltage at sending end at 230 kv. The illustration indicates that this capacity of synchronous reactor will hold the sending end voltage at about 227 kv. but the table of percentage error for this method indicates that the voltage at sending end as determined by this method is about 2.13 per cent low. The complete method would give the sending voltage as 230 under this condition. To maintain

FIG. 3

the same voltage (220 kv.) at both receiving and sending ends of the line about 20,000 kv-a. synchronous reactor capacity will be required as shown in Fig. 4.

Fig. 2 shows the performance of the system at normal load of 75,000 kw. per circuit and 220 kv. at the load. Under these conditions about 42,000-kv-a. synchronous condenser capacity will be required to hold receiving voltage at 220 kv. with an 85 per cent power factor load. If the voltage at sending end of the line is also held at 220 kv. with load conditions remaining the same, the synchronous condenser capacity required will be about 53,000 kv-a. as shown in Fig. 4.

Fig. 3 shows the performance of the system when emergency load of 150,000 kw. is carried by each circuit. This condition may exist for short intervals while one tower line is out of service for repairs. With

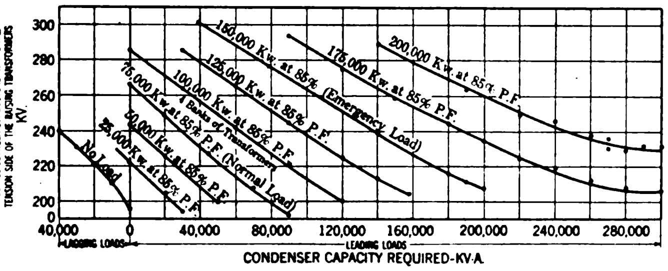

FIG. 4

230 kv. at sending end of line there will be required about 157,000 kv-a. synchronous condenser capacity to hold receiving voltage at 220 kv. with an 85 per cent power factor load. If voltage at sending end is also held at 220 kv. about 173,000-kv-a. condenser capacity will be required, as shown in Fig. 4.

Fig. 4 indicates, under various conditions of sending end voltage, the amount of energy which may be delivered to an 85 per cent lagging power factor load with 220 kv. at receiving end over this 225-mile, 60-cycle circuit consisting of three 605,000-cir. mil aluminum conductors. The synchronous condensers capacities corresponding to different sending end voltages are shown for various loads. It may be noted that with 230 kv. at sending end the maximum amount of power which can be transmitted over this circuit is about 200,000 kw. which will require synchronous condenser capacity at receiving end of about 300,000 kv-a.

The curve also shows that 25,000 kw. can be transmitted with about 222 kv. at sending end of line without any synchronous condenser capacity. It also shows that 75,000 kw. (normal load) could be transmitted with 266 kv. at sending end of line without any synchronous condenser capacity.

The following are the essential data on performance of some lines proposed for supply of energy to the superpower zone:

Power to be transmitted	300,000 kw.	300,000 kw.	300,000 kw.
Voltage at receiving end	220 kv.	220 kv.	220 kv.
Cycles	60	25	60
Length of line	350 mi.	350 mi.	115 mi.
No. of tower lines	2	2	2
No. of circuits per tower line	2	2	1
Size of conductors Aluminum	605,000 cir. mils	605,000 cir. mils	920,000 cir. mils
Steel	78,000 cir. mils	78,000 cir. mils	211,000 cir. mils
Normal load per circuit	75,000 kw.	75,000 kw.	150,000 kw.
Emergency load per circuit	150,000	150,000	300,000
Power factor of load	85 per cent	85 per cent	85 per cent
Power factor gen. end (normal load)	0.893 ld	0.884 ld	0.93 lg
Power factor rec. end (normal load)	0.983 lg	0.934 ld	0.97 lg.
Power factor gen. end (emergency load)	0.983 lg.	0.983 lg.	0.91 lg.
Power factor rec. end (emergency load)	0.879 ld.	0.894 ld.	0.98 ld.
Synchronous condenser capacity required (normal load)	152,000 kv-a.	90,000	141,000 kv-a.
Line losses (normal load)	29,800 kw.	36,360 kw.	13,800 kw.
Transformer core losses (normal load)	4,500 kw.	6,000 kw.	4,500 kw.
Synchronous condenser losses (normal load)	6,100 kw.	3,600 kw.	5,640 kw.
Total losses (normal load)	40,000 kw.	45,960 kw.	23,940 kw.
Efficiency of transmissions (normal load)	88.1 per cent	86.7 per cent	92.6 per cent

It may be of interest to note that in the 60-cycle, 350-mile line, with voltage held the same at both ends, the voltage in the middle of the line is approximately 6 per cent higher than at either end. In the 25-cycle line under similar conditions the "bulge" is only about 1 per cent.

The proper design of a transmission system requires special and thorough knowledge of the physical conditions to be met both in construction and operation of the line. The following points are applicable to all long-distance transmission systems:

(1) The right of way must be of ample width, in order that the conductors may be adequately spaced and so that there may be no danger of the conductors of adjacent lines coming in contact with each other. The right of way must be kept cleared so that growing trees cannot possibly come in contact with the conductors. Standing trees must be left so far away that when felled they do not reach the lines. Transmission lines have often been greatly hampered by inadequate rights of way; owners have had to be content with grants for use of public highways, or to make such terms as they could with private owners. In many cases easements could be obtained only on the basis that trees should not be trimmed except by special consent of the owners. This has resulted in many crooked lines, every bend involving a hazard. A transmission line of the magnitude we are considering is often a more important carrier than a railroad, and there should be laws granting the right of expropriation so that a right of way may be obtained commensurate with the importance of the service which it must render to the public. The lines should change direction as infrequently as possible, even slight curves should be avoided wherever possible. On account

of the expense and hazard involved in dead end angle towers tangents must be as long as the character of the country will permit. Wherever possible the right of way should be located away from cultivated areas, as the lines will then be less subject to interference from the activities of the people and the cost of the land will not be so great. Lines should not parallel railroads or communication circuits of any kind if this can be avoided.

(2) The transmission line should consist of steel towers with maximum spacing consistent with strength of conductors and most economical cost. For conductors of moderate size and under the usual assumptions as to limiting conditions of tower spacing will be as follows: For hard drawn copper about 800 feet, for steel reinforced copper about 1000 feet; for steel reinforced aluminum cables this may be increased to about 1500 feet. The configuration of the ground will probably call for many shorter or longer spans but these should be avoided when possible. Few towers mean few insulators, each of which is necessarily a danger point. The conductors for the 220,000 volt lines should be spaced at least 18-ft. delta, or its equivalent, but 21-ft. spacing is better. If vertical spacing is adopted the conductors should be staggered so that ice falling from one conductor may not cause a short circuit with the conductor below it. In areas where sleet prevails this matter must be given careful attention. Authentic records exist of sleet forming over 1½ inches in radial thickness on line conductors. In case the transmission line lies wholly within a sleet area the cost of construction to withstand this extreme loading may be prohibitive. In this case provision should be made so that during a sleet storm one or more of the circuits may be loaded until they are warm enough that ice will not form on them. The remaining line, or lines should be short-circuited and separate generators used to send enough current through them to keep them warm. This method has been used by one large transmission company for several years with entire success. In this way the lines may be preserved through a severe sleet storm and kept ready for service although it may be somewhat hampered while the storm lasts. With proper patrol organization the stations at the ends of the line should be kept informed of climatic conditions along the line at all times.

Clearance between conductors and towers should be such that with maximum wind deflection there will be no flash-over to ground. In the past this has been one of the most frequent causes of interruption to service.

(3) The strings of strain insulators should be graded or other means provided so that excessive voltage strains do not come on the units nearest the conductors, when lines are operated at 220,000 volts or higher. The writer sees no great objection to grading the disks, and a fairly even distribution of potential among the insulator units can be obtained in this way. It has been objected that linemen will not pay attention to orders and will install the first unit that comes to hand when it is necessary to make a replacement. After twenty years' experience in operating and maintaining transmission lines the writer believes that this is not a valid objection and that effective organization will prevent such happenings.

(4) Switching must be reduced to its lowest terms. There should be no taps from the transmission line between the step-up transformers at the generating station and the step-down transformers at the point of delivery. Where possible, switching should be done on the low-tension side of the transformers but a certain amount of switching to shift the load from one circuit to another on high-tension lines will be unavoidable. Manufacturers have successfully provided oil switches for 150,000-volt circuits involving comparatively large amounts of power, and switches for 220 kv. circuits will have no heavier duty as the currents are smaller. High reactance inherent in transformers and lines contribute to limiting the currents at time of short circuit to comparatively small amount, thus minimizing the duty imposed on oil switches.

(5) Neither overhead ground wires nor lightning arresters should be provided on circuits of 220,000 volts or higher as it is believed they will cause more trouble than they will prevent. Induced high-frequency charges will be absorbed by the large capacity of the lines and dissipated by corona.

While it is essential that the transmission system be properly designed and constructed, and that the physical conditions surrounding the line be under control of the operating company, the operating organization is of even greater importance. Years are required in which to build up an operating personnel which will get the best service from a transmission system. Eternal vigilance is the price of service, and this can be obtained only with an intelligent, loyal, well trained and well paid operating staff.

The Service That Can Be Expected From Long-Distance Transmission

Continuity of service cannot be readily evaluated. In a densely settled community where many thousands of people are entirely dependent on the public utility systems for light, power and transportation, it is customary to set a high value on continuity of service. Public utility companies have gone on the principle that absolute continuity of service, so far as humanly possible, is necessary, and they have provided large excess of generating capacity and duplicate feeder systems at great expense to accomplish this result. The utility manager has in mind the multitude of complaints that arise whenever an interruption to service, however slight, occurs and however small this inconvenience to the company's patrons

may have been. Human nature, in this age of rushing effort to accomplish work in its frantic pursuit of pleasure, is impatient at delay. An insignificant interruption to traffic in New York caused by failure of power supply furnishes opportunity for much complaint and publicity in the newspapers all of which is very embarrassing to the utility companies. It must be admitted that much of this frenzy for haste is infectious and is contracted from seeing others so impelled and not from any necessity in the case. Subway and elevated trains must be on time. The commuter hastens to his suburb only to sit down and read the paper for an hour before dinner. Broadway must be brilliantly lighted with thousands of lights every minute of every evening or the crowds are disappointed. In short the service must be perfect.

In some parts of our country large amounts of energy for transportation, power and lighting are brought from power plants located at waterfalls in the mountains. The people understand this and know of the various climatic and other elements beyond human control that may effect this service. A few times in a year there may be interruptions to the service. They do not like it but it is expected, no one is perceptibly the worse for it, and life goes on as usual. Now if these communities were to have the service demanded by New York City, there would have to be large reserves in generating plants, possibly steam plants in the cities would be required, the transmission lines would have to be duplicated and perhaps built along different routes and many other safeguards taken at very great expense. The people would have to pay the cost which might easily be double the price they are now paying for energy. Can they afford it? New York demands perfect service and, generally speaking, gets it. New York also pays for it. Can she afford it? Like many other things in New York the people pay for this superservice whether they can afford it or not.

The standard of service now given by many of our long-distance plants is not the best that can be attained for there is not one of these, if it were to be rebuilt at the present time, that could not improve its service, although the present standard is high and is being steadily improved. New long-distance lines now building are taking advantage of past experience and increased knowledge of the causes of trouble and means of preventing it. One of the reasons for trouble experienced in the past is that the developing companies were hampered by financial limitations. They could not build as well as they knew how for lack of money and had to do the best they could with the means available. When a plant is once built and in operation it is very difficult to raise additional money solely for the purpose of improving the service, and without expectation of increased revenue. Material improvement in service would generally mean entire reconstruction of the transmission lines and the earning power of very few plants would stand the additional cost.

In order to secure the opinion of those most favorably situated to judge as to whether energy transmitted over long lines can be delivered with the continuity necessary to satisfy the requirements of users of energy in the Superpower Zone, a series of questions were propounded to them premised by the assumption that the energy should be transmitted from either steam or hydroelectric stations ranging from 100,000 to 300,000 kw. in capacity over transmission lines of the highest grade of construction distances ranging from 100 to 300 miles.

Sixteen answers were received from prominent men holding responsible positions either as consulting or operating engineers of companies operating long-distance transmission lines in this country. These men, as well as the history of the transmission systems they are identified with, are well-known to engineers.

The answers received naturally reflected the experiences of the companies which these engineers represent. However, leaving out of account the psychology of the matter as affecting their answers there was practical unanimity of opinion that two tower lines, each supporting two circuits, each tower line with its circuits being capable in emergency of transmitting the entire load, would reasonably insure continuity of service of the character required by the metropolitan district of New York.

Long-distance transmission plants are not the only ones subject to interruptions. Local steam-electric plants are also subject to interruptions from storms, strikes, freight blockades, and from other causes. The remedy for this is numerous and varied sources of supply and interconnection of plants. This is now being carried out locally in various parts of the country particularly in New England, the south Atlantic states and in California, and is the method being proposed on a large scale by the Superpower Survey in the Washington-Boston district. When the whole country is connected with a large network of interconnecting lines between load centers, and these load centers are arranged for supply from local steam stations, large steam stations in neighboring cities, steam stations at the mines, and hydroelectric stations from sites both far and near, continuity of service will be assured far beyond what can be obtained from any single or local source of supply, however well safeguarded. The communities will then be practically independent of strikes or storms or meteorological conditions and will have better and more reliable service than can be obtained in any other way.

The author wishes to acknowledge the assistance of Messrs. William Nesbit, P. H. Thomas, and P. M. Lincoln, in preparing the diagrams and in the calculations, the results of which are given in this paper.

Carrier Current Telephony and Telegraphy

E. H. COLPITTS and O. B. BLACKWELL
Western Electric Co. American Telephone & Telegraph Co.

Concluded from page 421 of JOURNAL for May, 1921.

Commercial Apparatus and Installations

Under this section there is given a description of the apparatus which has been developed for commercial service and of the manner of employing it in actual installations in the Bell Telephone Plant. To date there have been developed and put into commercial use, three distinct types of multiplex carrier systems, as follows:

1. A carrier telephone system in which the carrier is transmitted.
2. A carrier telephone system in which the carrier is suppressed.
3. A carrier telegraph system

There has also been developed a two-way repeater set employing vacuum tubes, and suitable for use with any one of these three systems.

We will consider these systems in the order noted above, including the repeater more specifically under the first system, and will then discuss the general considerations as to their practical uses which are common to all the systems.

Carrier Telephone System Employing Transmitted Carrier. The apparatus which characterizes this type of system is indicated diagrammatically in Fig. 42, which shows the terminal circuit arrangement of one two-way channel.

This circuit can perhaps be most simply explained by tracing the path of currents involved in telephone transmission, which is shown by heavy lines in the figure. Voice frequency currents originating in the low-frequency line on the left pass through the low-frequency hybrid coil, *L H*, into the vacuum-tube modulator, *M*. There is likewise fed into the modulator the carrier current from the vacuum-tube oscillator, *O*, shown in light lines. Of the components of modulation appearing in the output circuit of the modulator, the transmitting band-filter, *T F*, suppresses all except one side band, either the upper or lower as desired, and the carrier, which it transmits or passes into the circuit common to all of the transmitting channels. The transmitting currents from this and the other channels then pass through the carrier hybrid coil and out on the carrier line.

The balancing networks, *L N* and *C N*, shown in Fig. 42, are important elements in determining the satisfactory operation of the system. The network, *L N*, on the left balances the low-frequency line and is similar to those used in ordinary telephone-repeater practise. The network, *C N*, on the right is of the type discussed above in the section on lines, and is illustrated in Fig. 35. It includes apparatus for balancing the office cabling and the line filters as well as the line itself.

The currents received from the line, which in the case of any given channel consist of one side band accompanied by its carrier, pass through the carrier hybrid coil and are selectively passed to the appropriate receiving circuits by means of the receiving

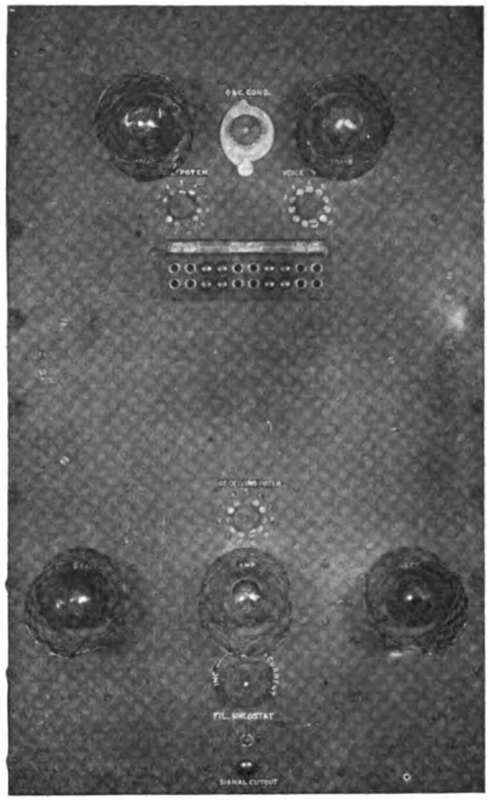

Fig. 43

band filters, one of which is shown at *R F*. The current passing through the filter *R F* is then amplified and demodulated in the two-stage vacuum-tube unit, *A D*, and the voice frequency currents appearing in the output circuit are selected from the other components of demodulation by the low-pass filter, from which point in the circuit they pass through the low-frequency hybrid coil, *L H*, to the connecting voice frequency line.

It should be pointed out that Fig. 42 indicates the points of connection for the transmitting and receiving circuits of the other two-way channels of the multiplex system, which are led to additional low-frequency lines through sets of apparatus which are exact dupli-

cates of the one shown, except for the modifications necessitated by the use of different frequencies over the different channels.

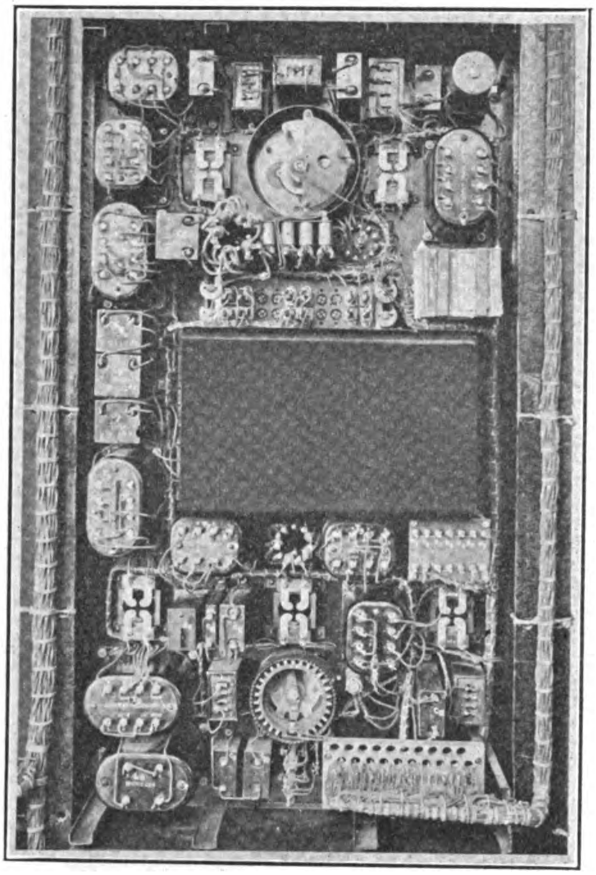

Fig. 44

The relays and the rectifier, employed in signaling by the methods already discussed, are also shown in the figure in light lines.

For convenience the apparatus itself is mounted on panels which are attached to relay racks in the central offices. The vacuum tubes peculiar to a two-way channel along with their immediately associated coils and other apparatus, are mounted on a panel by themselves, front and back views of which are shown in Figs. 43 and 44. At the top of Fig. 43 may be seen the oscillator and modulator tubes mechanically protected by wire cages, the control and dial of the condenser for adjusting the frequency of the oscillator, and similarly the potentiometers for controlling the supply of carrier and voice currents to the modulator. The jacks facilitate access to the various portions of the circuit for testing purposes. Below are shown the three vacuum tubes of the receiving circuit, the potentiometer for controlling the line current supplied to the detector input, the filament-current rheostat and a signal lamp with cut-out key. The remainder of the apparatus is mounted on the back of the panel, Fig. 44, and when installed is protected by metal covers.

An assembly of panels of the type just described, each associated with an individual carrier telephone channel, together with other apparatus about to be described, is shown in Fig. 45. At the left may be

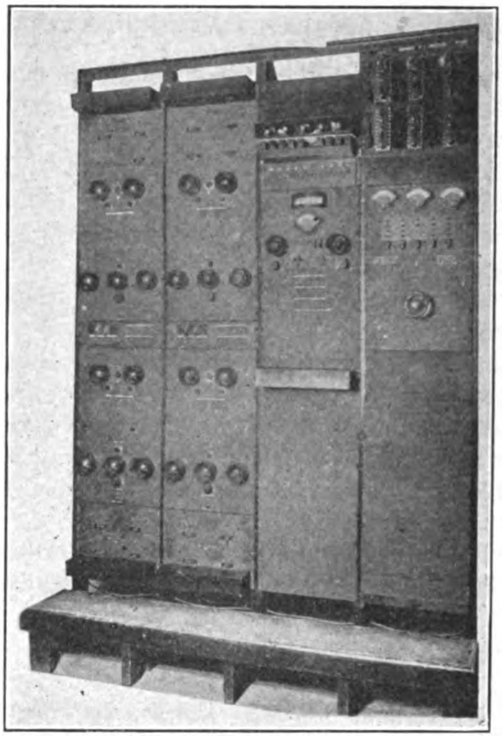

Fig. 45

seen four of the panels, three working in this instance and one spare, such as were shown in Fig. 43. The band-filters discussed above are mounted as individual units, of one of which a photograph is shown in Fig. 46. The coils and condensers are shown secured to a mounting plate; and this plate is clamped to the

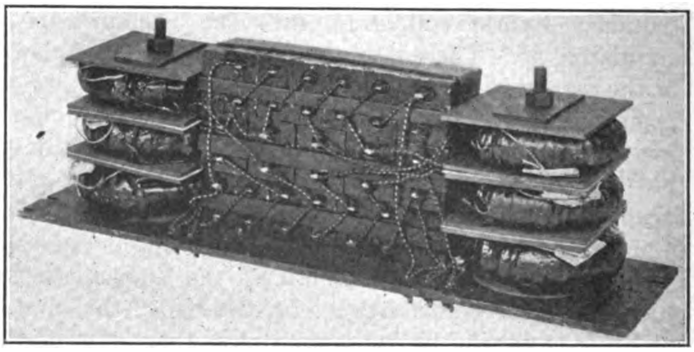

Fig. 46

vertical rack immediately adjacent to the vacuum-tube panel with which it is electrically associated. In Fig. 45 these filter-units may be seen located just above and below the vacuum-tube panels. In the two bavs to the right are mounted the apparatus controlling the power supply to the tubes, the apparatus used in the routine maintenance tests, and the hybrid coils and signaling relays.

The repeater set, which can be used with any of the carrier systems so far employed, embodies the circuits shown in Fig. 22. A front view of an actual set is

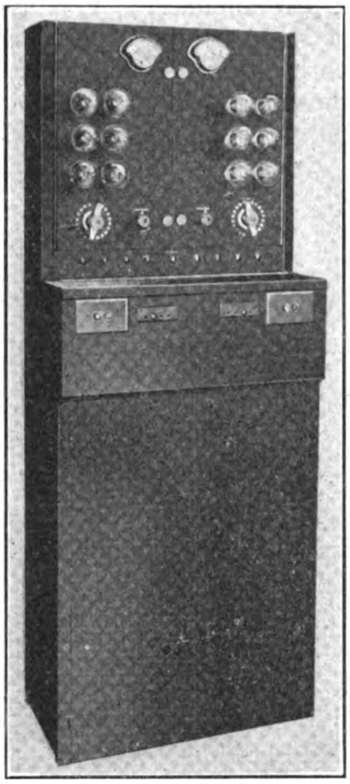

Fig. 47

shown in Fig. 47. This set includes the two-stage push-pull amplifiers, one for operating in each direction, and the necessary filters and hybrid coils for associating the set with the line. The balancing networks are located on shelves of a nearby rack. Also there is furnished a testing unit which may be associated with a number of such repeaters, usually up to four.

An illustration of an installation of this type is afforded by the Harrisburg-Detroit system, which is planned for New York-Detroit telephone service. A diagrammatic layout of this system is given in Fig. 48.

The carrier terminals are located at Detroit and Harrisburg, and the three carrier channels are brought from Harrisburg into New York as voice frequency circuits of the four-wire cable type. The system is provided with three intermediate repeaters at the points indicated. An additional open wire circuit between Harrisburg and Detroit is equipped with the necessary line filters at the terminals and the intermediate points, to make it readily available as a spare line-circuit. This spare line-circuit may be employed subsequently for a second carrier system. In its course from Harrisburg to Detroit the carrier system is superimposed upon two different voice frequency circuits in turn. One of these is a New York-Chicago circuit, which the carrier system takes between Harrisburg and Beaver Dam, at which point it deviates from the route pursued by the carrier system. The remaining portion follows a different voice frequency circuit from Beaver Dam to Detroit. This illustrates the possibility of transferring the carrier systems from one voice frequency circuit to another en route. The separation of the carrier channels from the regular voice frequency channel, at each of the intermediate points, enables the two sets of channels to be handled entirely independently of each other in their operation and maintenance. For example, at Pittsburgh a

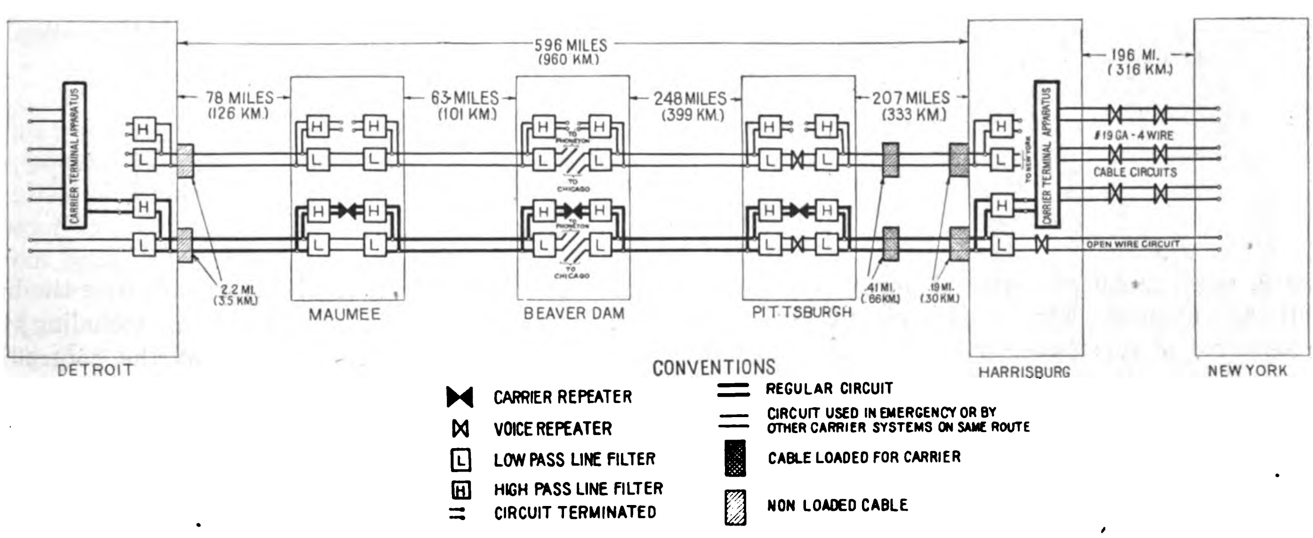

Fig. 48

repeater is inserted in the voice frequency circuit as well as in the carrier frequency channels, while at Beaver Dam and Maumee the repeaters are inserted in the carrier channels only. The occurrence of sec-

tions of intermediate cable in the system is indicated in the figure. The effect of the cable sections between Harrisburg and Pittsburgh was specifically referred to in the section on Lines.

Carrier Telephone System with Suppressed Carrier. The second type of carrier telephone system has been designed to operate on the principles of carrier suppression and harmonic carrier generation which were quite fully discussed above. In comparison with the system just described it is rather more complex and the base-frequency amplifier which selectively amplifies this frequency and supplies it to the line as shown. In the transmission circuit it will be noted that in addition to the balanced modulator, *M*, already described, a push-pull amplifier, *T A*, is used to increase the volume of side-band current transmitted. The high-pass filter between the modulator, *M*, and amplifier, *T A*, prevents the latter from being overloaded by the voice currents in the output of the modulator. The balanced demodulator, *D M*, serves to prevent

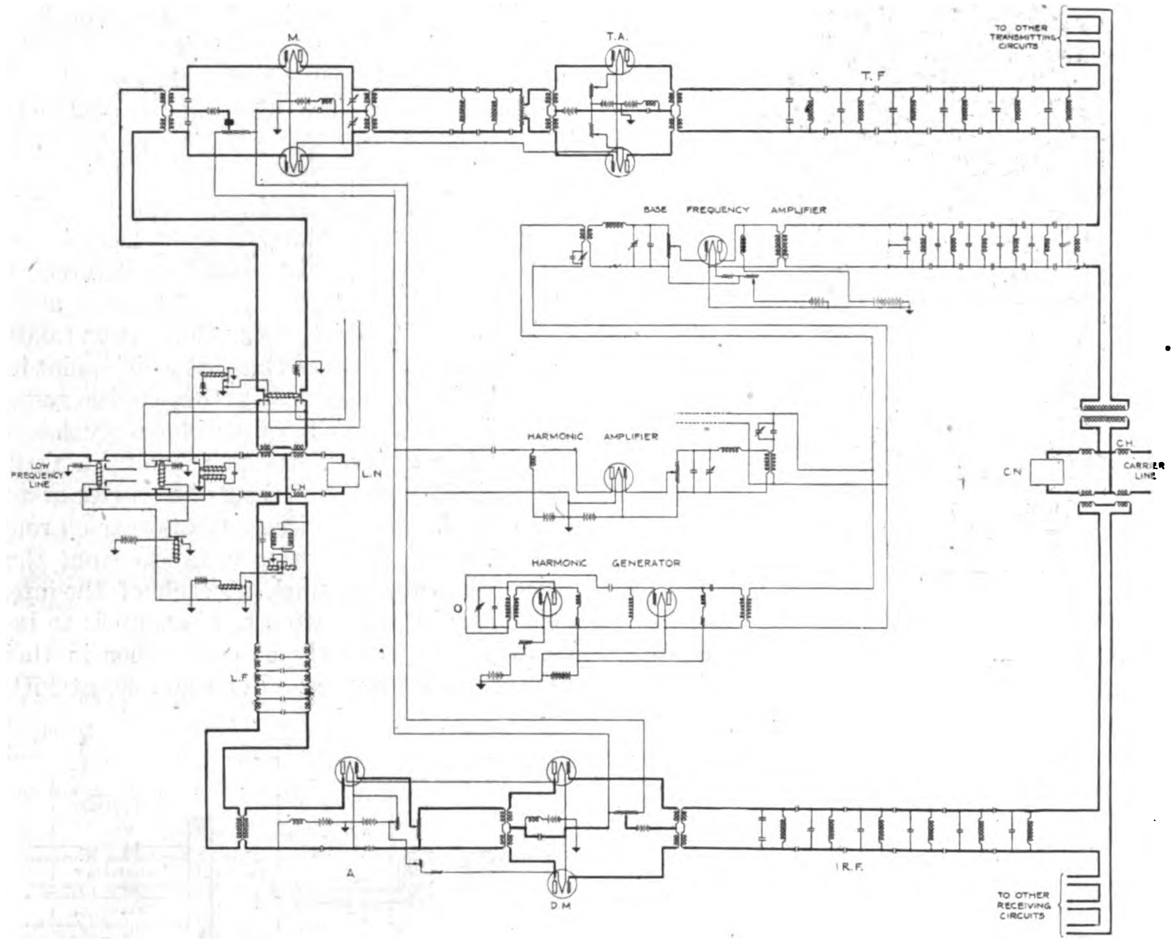

Fig. 49

there is more auxiliary terminal apparatus common to all the channels. Fig. 49 is a circuit diagram of one terminal of one two-way channel together with the common carrier-supply circuits. As usual, the transmission circuits are indicated by heavy lines, while the light lines show the carrier-supply and the signaling. The system indicated is one designed to use the same carrier frequency for both directions of a two-way conversation. Therefore the harmonic generator is shown as feeding through the same selective circuit and harmonic amplifier, into the modulator, *M*, and the demodulator, *D M*. The harmonic generator is supplied with the base frequency from the oscillator, *O*, and in addition to supplying the harmonics it also supplies the base frequency to the terminals of the transmission of the local carrier back over the line. The carrier-supply apparatus shown, including the harmonic generator, is that used at the controlling station. At the distant station the arrangement is modified to provide for amplifying the base frequency received from the incoming carrier line and supplying it to a harmonic generator which supplies the various frequencies through the amplifier to the modulators and demodulators associated with each channel.

The apparatus for this system has been mounted on unit racks of self-supporting type. One such unit holds the sending apparatus for one channel and another the receiving apparatus. Illustrations of these are shown in Figs. 50 and 51. Apparatus such as tubes

and potentiometers is located with convenient accessibility and the space below is used for filters, condensers and other apparatus which requires practically no attention or adjustment. Similar racks are used for the base-frequency oscillator and harmonic generator, the harmonic amplifiers, the testing circuits and the auxiliary low-frequency apparatus.

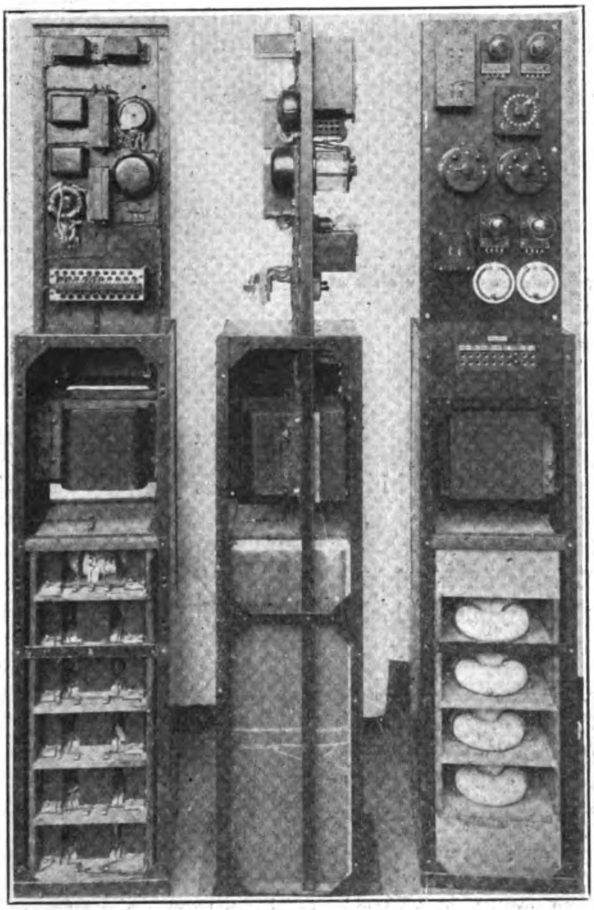

Fig. 50

This type of apparatus is employed, for example, in the Harrisburg-Chicago system, the circuits of which are extended into New York as voice frequency circuits in order to provide New York-Chicago service. This system spans a somewhat greater distance than the Harrisburg-Detroit and includes four intermediate carrier repeater stations. Fig. 52 shows diagrammatically the layout of the whole system. For insurance of service a second set of line wires is arranged for carrier operation as illustrated. In general the plant features are the same as in the case of the Harrisburg-Detroit installation above. Because each carrier circuit in this system employs the same carrier frequency for transmission in the two directions, greater care was taken to make the lines of uniform impedance and to simulate them with their associated balancing networks.

In the Harrisburg-Pittsburgh section, this system is operated over the same pole line as is the one previously described and also with a multiplex carrier telegraph, later referred to. This has required a special transposing of the line wires between these two points.

The appearance of the apparatus at the terminal offices is shown by Fig. 53, which is that located at the Chicago terminal. In the center of the group of panels is seen the test panel by means of which the routine maintenance tests of the apparatus and lines are made.

A typical repeater installation at an intermediate office is shown in Fig. 54, which is that located at Cleveland. Two repeater units, one a spare unit, are provided; and located beside them is the testing unit employed for maintenance tests and switching.

Carrier Telegraph System. The fundamental circuit of a carrier telegraph channel has already been shown in simplified form by Fig. 23. Fig. 55 shows the circuits for associating ordinary telegraph sending and receiving loops with one terminal of a duplex carrier telegraph channel. It also shows

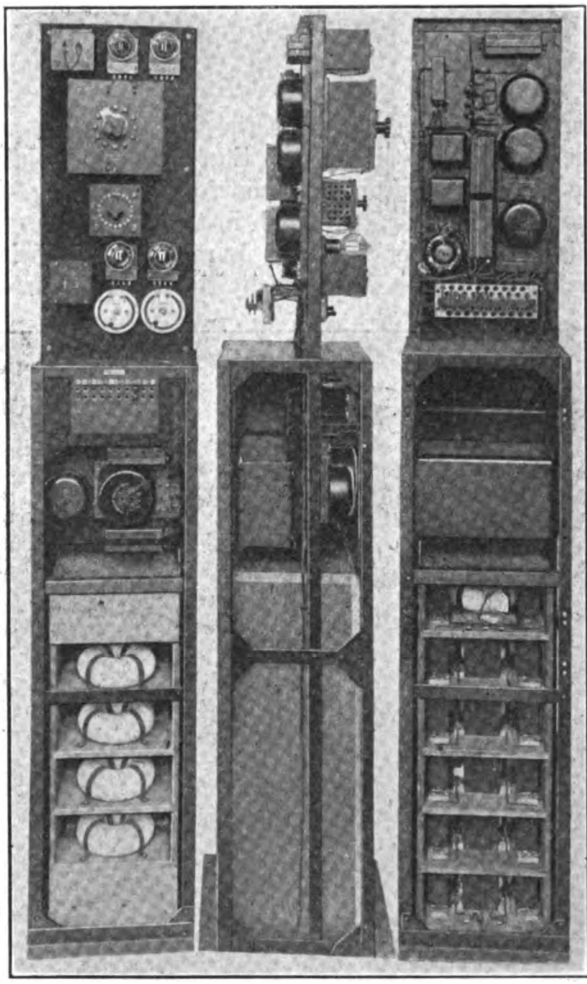

Fig. 51

schematically the high-frequency side of the system including the selective circuits and the vacuum-tube apparatus. The operation of the high-frequency side of the system will be clear from a consideration of the simplified telegraph circuit and from what has been said of the operation of the very similar carrier telephone apparatus. It may be said, however, that the

discrimination by tuned circuits between the sending and receiving channels which are of different frequencies is supplemented by the line-balancing arrangement shown, as in the telephone system first described above.

mounted on a self-supporting rack Fig. 56. On the front of the panel may be seen the vacuum tubes, the meters for observing the signaling currents, the sounders and key for monitoring, and the switches

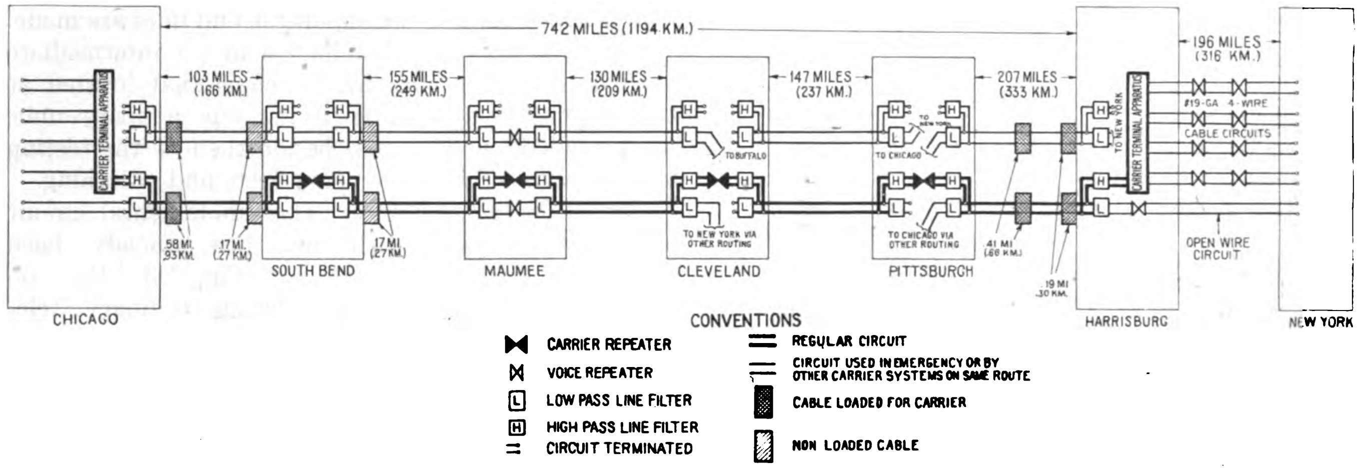

Fig. 52

Referring to the operation of the low-frequency side of the system, it will be seen that the manipulation of the sending operator's key controls the sending relay of the carrier apparatus which in turn impresses the signals on the carrier current. In receiving, a sensitive polar relay is shown, operated by the rectified current,

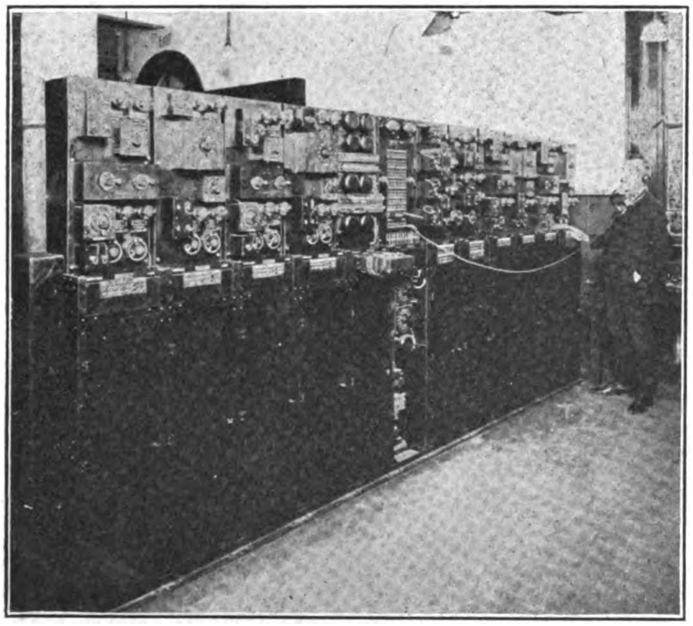

Fig. 53

which in turn transmits the signals into the local subscriber's loop in the form of the usual direct-current impulses. In the actual apparatus switches are provided by means of which the sending and receiving channels are associated with a common subscriber-loop for half-duplex operation.

The apparatus for one terminal of one full-duplex carrier telegraph channel, represented in Fig. 55, is

associated with the subscriber's loop circuit. The panel at the top is hinged to afford ready access to the apparatus mounted on the back. In the lower compartment are located the tuned circuits, the adjustable condensers of which are visible. Below these can be seen the cylindrical case which contains the sensitive receiving polar relay.

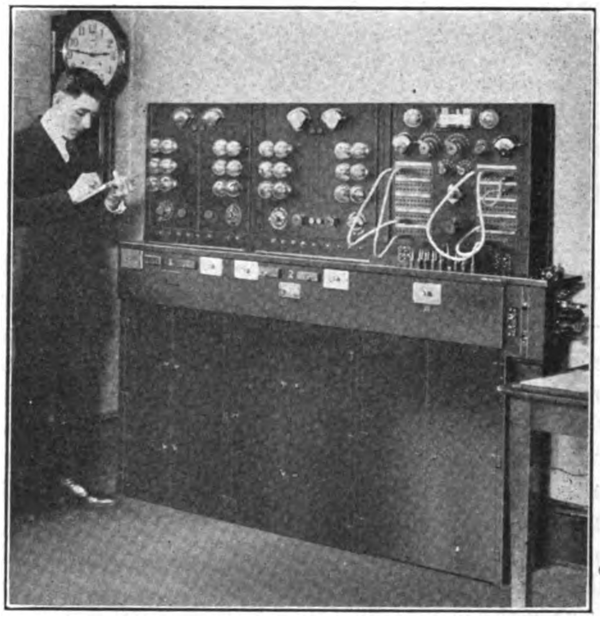

Fig. 54

Fig. 57 shows a group of carrier telegraph sets with an associated testing unit constituting a part of a complete installation located at Pittsburgh. At the top of the testing unit may be seen the relay and sounder of a regular test wire which extends along the route taken by the carrier system, a meter for measuring high-frequency line currents and the dials associated

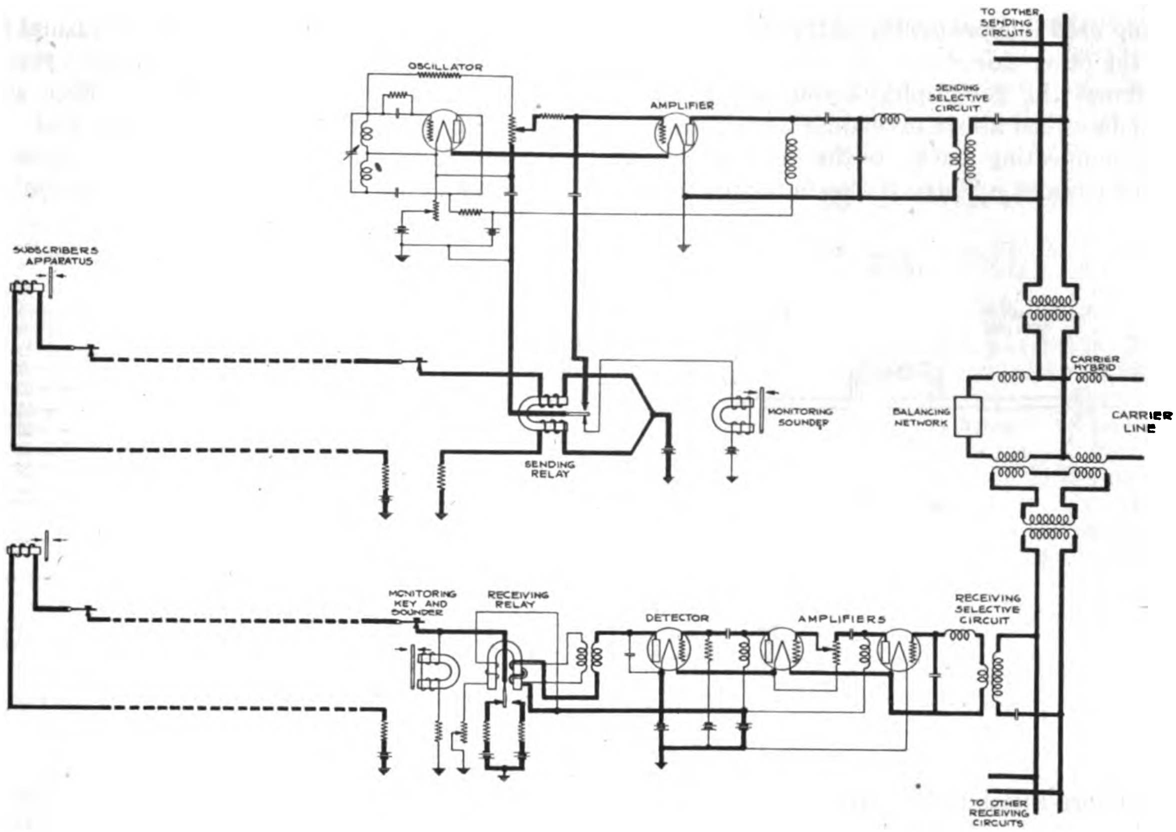

Fig. 55

with an oscillator for testing purposes. The jacks afford access to circuits of any of the carrier telegraph panels grouped with the test unit.

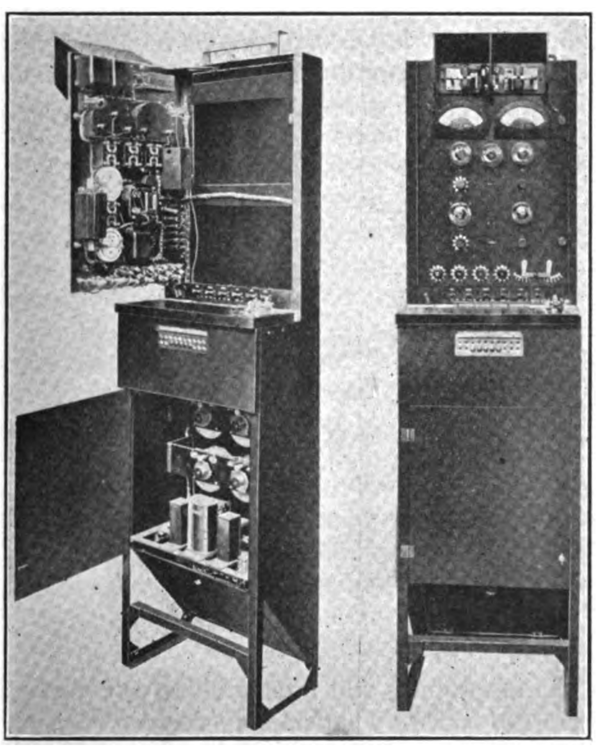

Fig. 56

The layout of the ten-channel Harrisburg-Chicago carrier telegraph system which includes the equipment of Fig. 57 is shown in Fig. 58. The circuits connecting the Harrisburg terminal to New York, where the most of the telegraph business terminates, are also shown. Pittsburgh, it will be noted, is not made merely a repeater station, as is Beaver Dam, but instead is

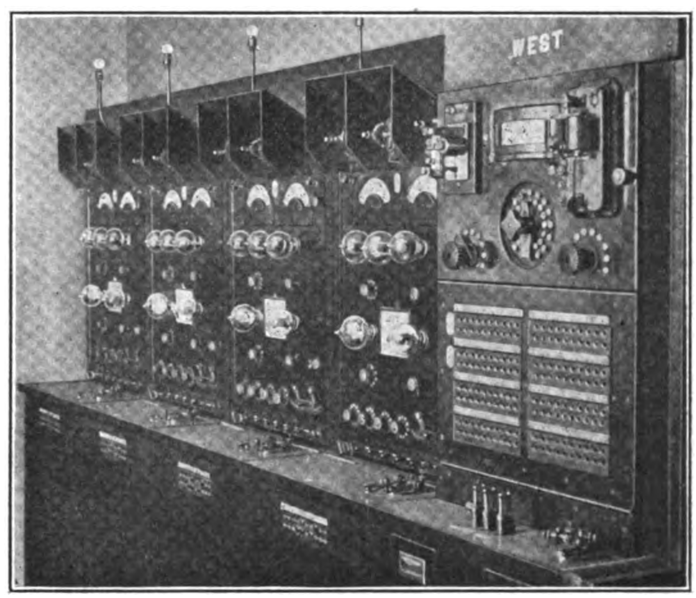

Fig. 57

equipped with two complete sets of carrier telegraph terminal apparatus. This is done to permit of connection between the through channels and local telegraph loops and also to permit of any one channel on

one side being used independently of the corresponding channel on the other side.

Fig. 59 shows the geographic layout of the three installations described above extending west from Harrisburg and connecting back to the seaboard cities through cable circuits. There is also indicated on this map the Baltimore-Pittsburgh telephone system, which was originally installed for giving Washington-Pittsburgh service.

General Considerations. An important aspect of the carrier developments described above is that they have placed the art upon a quantitative basis and enabled carrier installations to be engineered and put into operation in much the same way as is done for regular repeater telephone circuits. The transmission layout of the system is determined from a consideration of data on line characteristics and from the characteristics of the apparatus. In carrying out an installation, a certain amount of preparatory work must usually be done on the lines, including particularly the loading of intermediate sections of cable and transposition work. In the offices, the apparatus is installed in much the same way as are the more usual forms of telephone equipment, taking certain precautions, however, to minimize the lengths of office wiring included in the high-frequency circuits and to avoid cross-talk in the wiring interconnecting the individual apparatus units. The battery supply currents for the vacuum tubes are usually furnished from the existing 24-volt telephone batteries and 120-volt Morse batteries.

The grade of service given by carrier circuits, both telephone and telegraph, is as a rule quite up to the high standards which prevail for the long-distance circuits of the Bell plant. Not only is it possible to deliver the volume of transmission necessary for enabling the carrier circuits to be greatly extended by the addition of ordinary circuits at the ends, but also the naturalness and intelligibility of transmission is preserved to a very satisfactory degree.

The carrier telephone channels are terminated in the long-distance switchboards in the usual way as, for example, at New York and Chicago for the Harrisburg-Chicago system described above; and connections

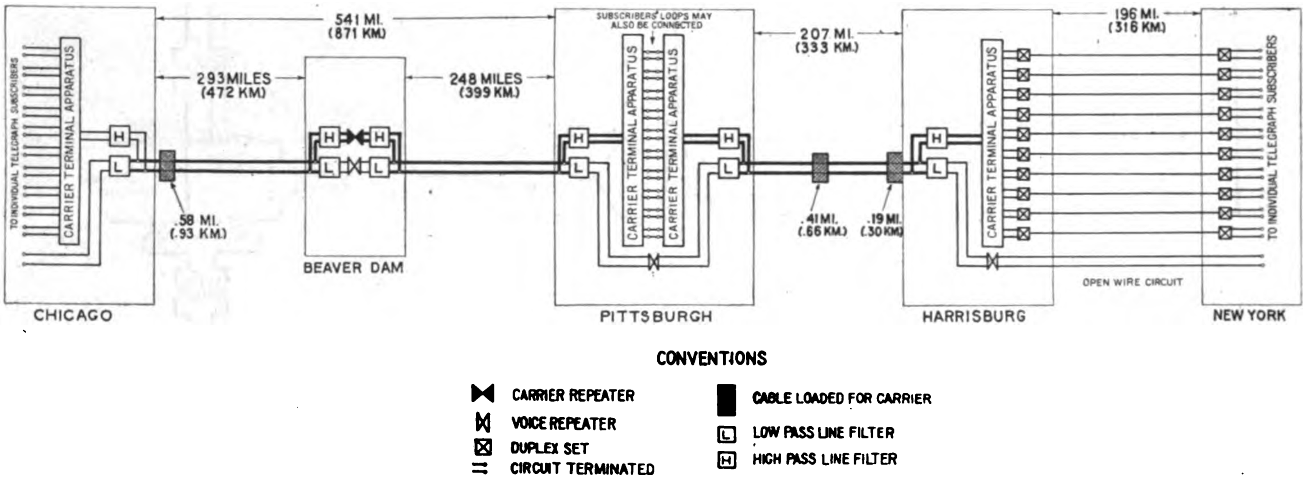

Fig. 58

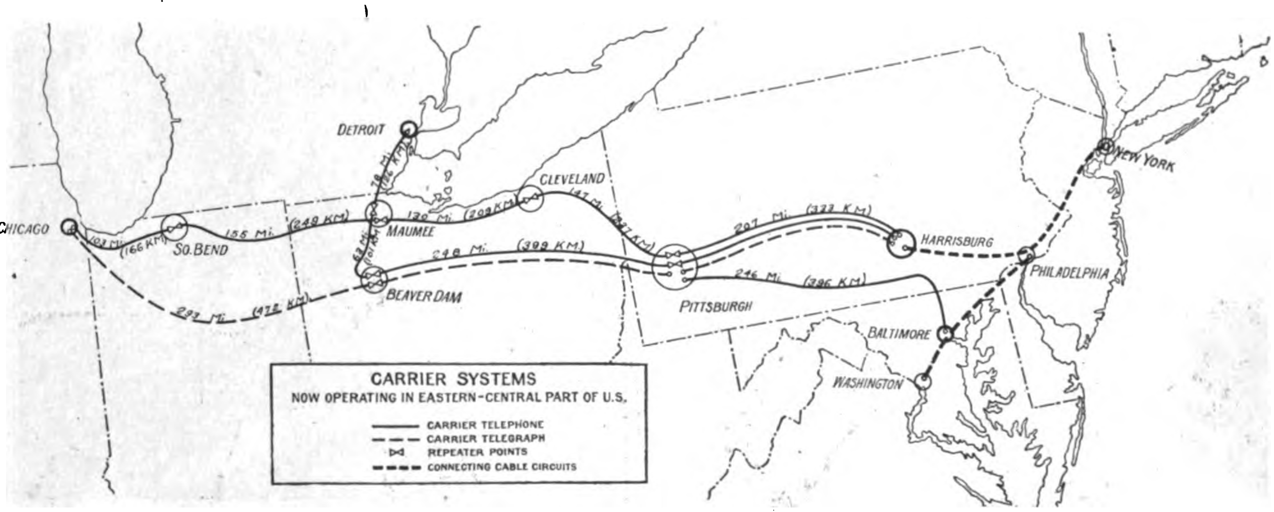

Fig. 59

are put up by the long-distance operators, using the regular toll cords. In fact, to the operators such circuits are indistinguishable from the regular long-distance repeatered circuits. The operator rings at the terminals of the connecting circuits in the standard manner, and the signals are automatically relayed over the carrier telephone channel as indicated in the circuit diagrams above, so that each carrier telephone channel is provided from end to end with its own signaling channel. The satisfactory working out of such operating features as these has been of much importance in completing the commercial usefulness of carrier telephone systems.

As has been indicated above the carrier telegraph systems as well as the carrier telephone systems, are designed to fit as an integral unit into a comprehensive wire plant, the relay-circuit arrangements providing for automatic repetition between the carrier channels and the connecting circuits, whether the latter be subscribers' loops or an additional section of long-distance circuit. The carrier telegraph circuits are used in the Bell plant, as are the regular composited Morse circuits, to furnish leased-wire service. The requirements for this service are particularly exacting as regards continuity and quality. The carrier telegraph circuits have proved to be very satisfactory in meeting these demands.

Reference was made in the first part of the paper to the fact that the carrier apparatus required for meeting the high standards of operation of a public service communication system is expensive. The technique involved in the art is so fascinating that one may readily lose sight of the more practical matter of costs, but to the engineer the economics of the situation are all-important, for it avails nothing if it is not possible to accomplish by the new method the same, or better, results than were obtainable with the old, at no greater cost. Carrier telephone systems—at least in the present state of the art—are economical in a general public service communication system only for use over relatively long distances. Of course, whether carrier can be justified in any given case depends upon factors peculiar to that case; in some instances, for example, it may not be physically possible to provide additional wires over a given toll line or cable route, in which case the relatively high apparatus costs may be easily justified. The carrier telegraph system is also essentially a long-distance proposition, although it is sometimes possible to warrant its use for distances somewhat shorter than in the case of telephone systems.

The authors wish to state that this paper is based largely upon the results of the engineering and research work of a great number of engineers on the staffs of Col. J. J. Carty, Vice-President of the American Telephone and Telegraph Company, and of Col. F. B. Jewett, Chief Engineer of the Western Electric Company. They desire particularly to acknowledge their obligations to Messrs. R. V. L. Hartley and Lloyd Espenschied, who, in addition to their very valuable contributions to the development of the art, have rendered special assistance to them in the work of preparing this paper.

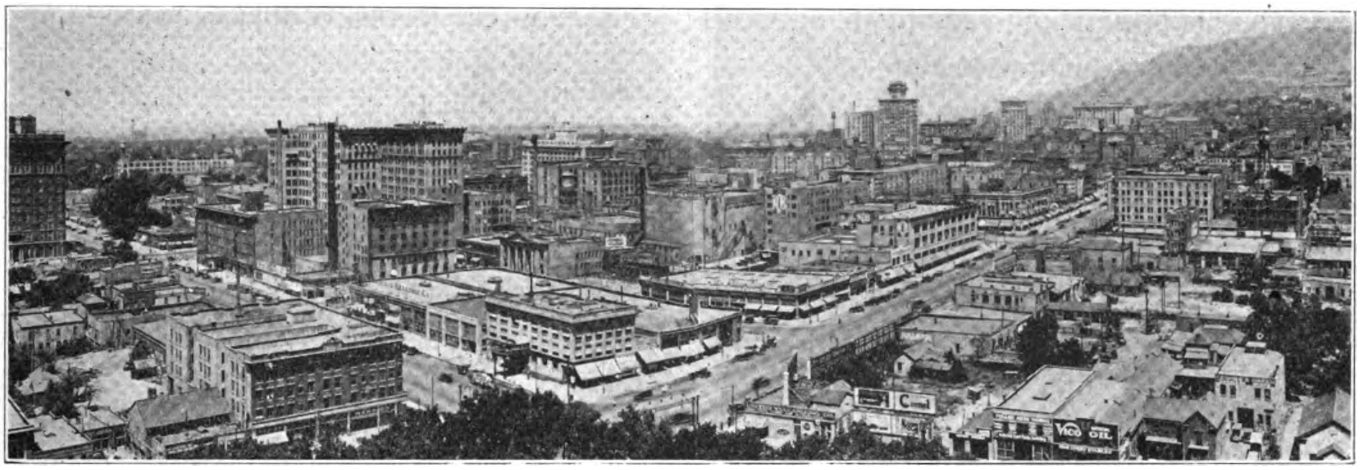
1919 TRANSACTIONS ERRATA

In the paper on "Problems of 220-Kv. Power Transmission," by A. E. Silver, published in Part 2 of the A. I. E. E. TRANSACTIONS, Vol. XXXVIII, 1919, Figs. 4, 5, and 6 on pages 1050, 1051, and 1052 each have one curve incorrectly drawn. These curves show transmission line characteristics. Correction slips are being prepared in the form of pasters, and will be sent on request to any one desiring to make these corrections.



SALT LAKE CITY FROM COUNTY BUILDING

Annual and Pacific Coast Convention

Salt Lake City, Utah, June 21-24, 1921

In the joint Thirty-seventh Annual and Tenth Pacific Coast Convention the Institute has provided an unusual opportunity to combine all the pleasures and benefits that are coincident with attendance at the yearly national meetings, with a trip to the center of scenic America. The Convention Committee and the Utah Section have arranged a program of technical sessions, excursions, dinners, lectures, recitals; tennis, golf and baseball; a program every detail of which has been so carefully mapped out, that arrangements to attend can be made with the full assurance that no effort has been spared to make this year's Convention a signal success.

Ladies are especially invited to attend and will find the afternoon and evening events of particular interest.

Institute headquarters will be located at the Hotel Utah and all technical sessions will be held there. Information Bureau and Registration Booth will be located on the mezzanine floor of the hotel.

An outline of the program follows:

Tuesday, June 21

The convention will open on Tuesday morning, June 21, 10.00 a.m. with an Address of Welcome by Charles R. Mabey, Governor of Utah, followed by the Annual Presidential Address by Arthur W. Berresford. A technical session will then take place. Directly succeeding the technical session, a luncheon for the Section Delegates is scheduled. This will serve as an opportunity for the delegates to become acquainted and to discuss points of interest to the Sections. Tuesday afternoon there will be a trip on foot past the most interesting, historical, Latter Day Saints buildings, followed by a short lecture and organ recital in the Tabernacle. At 7:00 p.m. an auto trip has been arranged to reach the famous Wasatch Boulevard at sunset and later to Capitol Hill. A return will be made to the Hotel Utah in time for an informal reception at 9:30 p.m., followed by dancing.

Wednesday, June 22

Wednesday morning, 9:30 a.m., the second technical session will be held. On Wednesday afternoon, a special train will leave from the Oregon Short Line depot at 12:30 p.m., over the Bingham and Garfield Railroad. Lunch will be served on the train. This trip, in addition to magnificent views of Great Salt Lake and Salt Lake Valley will provide an opportunity for Institute members to inspect a typical mining canyon. surface workings of the largest metal mine in the world with mills and smelters. On Wednesday evening there will be a meeting of the Section Delegates and Officers of the Institute, which will be open to all interested. A piano and harp lecture recital is scheduled for the evening at 8:30 p.m., Hotel Utah.—Mrs. Jacob A. Kahn, Pianist and Mrs. Marsh B. Boothby, Harpist.

Thursday, June 23

Thursday morning, beginning 9:30 a.m., will be devoted to the third technical session. The Board of Directors will meet at luncheon Thursday noon, and follow the luncheon with a short business meeting. For the forenoon, a special Entertainment for the ladies has also been scheduled, with a luncheon at the Literary Club. Thursday afternoon is assigned to an automobile trip to the Utah Power and Light Company's Terminal Station, the terminus of three 130,000-volt transmission lines, and said to be the largest outdoor substation in the world. Arrangements will also be made for those who wish to devote the time to golf or tennis. For the after-dinner entertainment, Dr. Broaddus will deliver an illustrated lecture on the wonderful canyons of Utah.

Friday, June 24

Friday morning, June 24, 9:30 a.m., is assigned for the presentation of various miscellaneous technical papers. On Friday afternoon, the finals of the Golf and Tennis Tournaments will be held. A baseball game between Eastern and Western members will start at 2:00 p.m. Bathing at Saltair Beach is scheduled from 5:00 p.m. to 7:00 p.m., followed by a Big Western Dinner in the Ship Cafe, with dancing for those who wish it.

Saturday, June 25

On Saturday, various *After Convention Trips* have been planned to local points of engineering interest, such as electric railways, power stations, pumping plants, smelters, mills, etc. Trips can also be made to Mountain Parks, Canyons, Brighton, Park City, and Bird Island, or to the Shoshone Falls, Bryce Canyon, Zion Canyon, the Grand Canyon and Yellowstone Park. For details see "After-Convention Trips and Excursions" below.

TENTATIVE PROGRAM OF TECHNICAL SESSIONS

Tuesday, June 21—10:00 A. M.

Welcome Address, by Charles R. Mabey, Governor of Utah.
President's Address, by Arthur Berresford.

Technical Committee Reports

Hydroelectric Developments at Niagara Falls, by J. L. Harper, and J. A. Johnson, both of Niagara Falls Power Company, Niagara Falls.

Modern Developments in Waterwheels, by W. M. White, Allis-Chalmers Co.

Wednesday, June 22—9:30 A. M.

Long Distance Transmission of Electric Energy, by L. E. Imlay. Superpower Survey, New York, N. Y.

Voltage and Power Factor Control of 66,000-Volt Transmission Lines Connecting Two Generating Stations, by Raymond Bailey, Philadelphia Electric Company.

Symposium on Long-Distance Transmission Systems.

a. *Voltage Regulation and Insulation for Large Power Long. Distance Transmission Systems,* by F. G. Baum, Consulting Hydroelectric Engineer, San Francisco, Cal.

b. *Some Transmission Line Tests,* by W. W. Lewis, General Electric Co., Schenectady, N. Y.

c. *Notes on the Operation of Large Interconnected Systems,* by L. L. Elden, Edison Electric Illuminating Co., Boston, Mass.

Modern Production of Suspension Insulators, by E. H. Fritz, Pittsburgh High-Voltage Insulator Co., and G. I. Gilchrest, Westinghouse Electric & Mfg. Company.

Thursday, June 23—9:30 A. M.

Voltage and Current Harmonics Caused by Corona, by F. W. Peek, Jr., General Electric Co., Pittsfield, Mass.

A Solution of the Porcelain Insulator Problem, by E. E. F. Creighton, General Electric Co., Schenectady, N. Y., and F. L. Hunt, Turners Falls Power & Electric Company.

Transformers for Interconnecting High-Voltage Systems or for Feeding Synchronous Condensors from a Tertiary Winding, by J. F. Peters and M. E. Skinner, both of the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

Electric Strength of Air Under Continuous Potentials and as Influenced by Temperature, by J. B. Whitehead and F. W. Lee, both of Johns Hopkins University, Baltimore, Md.

Friday, June 24—9:30 A. M.

Little Things from Little Places, by Guido Semenza, Local Honorary Secretary of A. I. E. E., for Italy; Consulting Engineer, Milan, Italy.

Synchronous Motors for Ship Propulsion, by E. S. Henningsen, General Electric Co., Schenectady, N. Y.

Magnetic Properties of Compressed Powdered Iron, by Buckner Speed and G. W. Elmen, both of the Western Electric Co., New York, N. Y.

Heat Losses in Conductors in A-C. Machines, by W. V. Lyon, Massachusetts Institute of Technology.

HOTEL RESERVATIONS

All members expecting to attend the convention should make their hotel reservations immediately. Address communications to Hotel Committee, A. I. E. E., 1212 Walker Bank Bldg., Salt Lake City, Utah.

HOTEL RATES, EUROPEAN PLAN

Hotel Name	Double Room One or Two People		Single Room One Person		Approximate Number Rooms
	With Bath	Running Water	With Bath	Running Water	With Bath
Utah	$8.00	$5, $6			
*Newhouse	$4, $5, $6	None	$3, $3.50, $4	None	100 All with bath
Kenyon	$3.50	$2, $2.50	$2.50	$1, $1.50, $2	40 to 50 rooms
New Grand	$3, $4, $5, $6	$2.00	$2, $2.50, $3	$1.50	30 rooms
Moxum	$4.00	$3.00	$3.00	$2.00	40 rooms
Semloh	$3, $3.50	$2.00	$2, $2.50	$1.25, $1.50	50 rooms
Wilson	$3.00	$1.50, $2	$2.50	$1, $1.50	30 rooms
Cullen	$3, $3.50	$2,$2.25,$2.50	$2, $2.50	$1.25, $1.50 $1.75, $2	25 to 30 rooms
Peery	$2.50,$3,$3.50	$2, $2.50	$2, $2.50	$1.50, $2	30 to 40 rooms

*Also 25 rooms with 2 single beds in each at $6.00.

TRANSPORTATION

It is important that members consult their local railroad agents and decide on the exact and most advantageous route to and from Salt Lake City for their purpose, and make their reservations as early as possible. Summer Excursion Rates take effect June 1st, offering round trip fares considerably below those now prevailing. These tickets permit stop-overs en route and are good until about October 31st.

Arrangements can be made to visit Yellowstone Park, the greatest scenic drawing card in the western United States, either enroute to or en route from the convention. The actual round trip fare via Yellowstone will not exceed that to Salt Lake City, and return, direct, the only additional expense being for transportation and accommodations in the Park. All expenses for the 4½ day trip through the Park amount to $45.00 via auto and camp route, and $54.00 via auto and hotel route.

As a very large number of eastern members will, of necessity, pass through Chicago, it is pointed out that the last train leaving Chicago in time to reach Salt Lake City for the first Convention session, Tuesday morning, June 21st, is train No. 19 over the Chicago and North Western R. R. and Union Pacific R. R. This train leaves Chicago 10:30 a. m., Sunday, June 19th, arriving in Salt Lake City at 8:20 a. m., Tuesday, June 21st. The round trip fare (summer excursion rates, all roads) from Chicago to Salt Lake City will be $77.76. Persons wishing to go over this route on the train mentioned above should communicate with E. E. Bogardus, City Agent, Chicago & Northwestern R. R., 148 S. Clark St., Chicago, Ill., and obtain their Pullman reservation; additional cars will be added to the train to meet the demand.

Those wishing to return via Kansas City or St. Louis can make the trip via the Denver & Rio Grande R. R. and the Missouri Pacific, passing through the magnificent Royal Gorge.

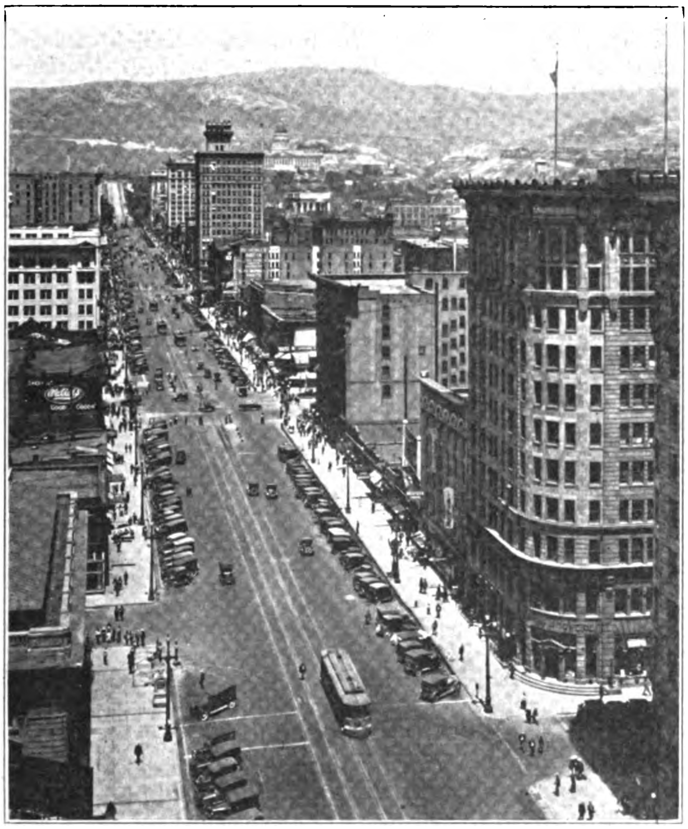
It is assumed that some members will wish to extend their trip to the Pacific Coast, and in that event should purchase Pacific Coast Summer Excursion tickets at their initial point, with stop over at Salt Lake City; similarly, members from the Pacific Coast may obtain summer excursion rates to points in the East with stop over at Salt Lake City.

SPORTS

Mershon Golf Cup. The Mershon Golf Cup will again be offered in competition. In the conditions of gift Past-President Mershon stipulated that to become the personal property of any member of the Institute he must twice win the golf tourna-

ment. So far, six golf enthusiasts have their names inscribed on the trophy.

John B. Fisken Cup. This cup, presented to John B. Fisken by the Portland Section, will also be competed for but by members of the Pacific Coast Section only. The winner of the golf tournament at which it will be offered will hold the cup only for the succeeding year.



BUSINESS DISTRICT, SALT LAKE CITY

In addition to the Golf and Tennis Tournaments and the Baseball Game between Eastern and Western members it will be possible for those members desiring to devote more attention to this feature to arrange for additional tennis or golf. The gymnasium of the Latter Day Saints immediately adjacent to the hotel will be available for the free use of members and will afford special bathing and exercise at any time of day.

LADIES ENTERTAINMENT

The Chairman of the Ladies Entertainment Committee has prepared a program which will provide a very wide range of entertainment. An effort will be made to have available at all times for those ladies who desire them, automobiles, guides to the Country Club, parks or canyons; tennis courts, gymnasium privileges; all kinds of bathing, sulphur water, fresh water, salt water. Six excellent bathing resorts including two hot springs are close to the city. Salt Lake City has many excellent stores and theatres. The wives of local members are planning to entertain the ladies with luncheons, theatre parties, drives, etc., during the time allotted to technical sessions. As a particular point of interest the committee calls attention to the fact that the National Federation of Womens Clubs will hold its annual convention in Salt Lake the week of June 12 to 16.

AFTER CONVENTION TRIPS AND EXCURSIONS

The following brief summaries give information regarding cost, method of transportation and time required for a number of trips which will interest engineers, both from the professional or educational standpoint and the scenic.

In the Rocky mountain country in which the Convention will be held, the electrical energy used is almost entirely developed by water power. Engineers interested in the production, transmission and distribution of power will have opportunity to see how it is done under very difficult topographical conditions. A number of the trips outlined show the application of hydroelectric power to the mining industry and how the problems of transmission are met.

A Bureau of Information will be maintained in the Hotel Utah where full information regarding any of the trips mentioned may be obtained and where visitors should register for such trips as they may desire to make.

Park City. The richest silver camp in the world and oldest in Utah. Elevation, 8000 to 11,500 feet. Located about 35 miles east of Salt Lake City on the Denver and Rio Grande Railroad, on transcontinental automobile route, an easy hour and a half drive from the city through beautiful Parley's Canyon. The largest electrolytic zinc plant in the west is located here. Representatives of the Utah Power and Light Company will welcome all visitors and conduct them on inspection. Reached by railroad or stage; fare approximately: $5.00. Time required: one day.

Eureka. Elevation, 6400 to 11,000 feet. Eureka is without doubt the most interesting metal mining camp in Utah. Produces copper, lead, zinc, silver, gold, iron and many of the rarer minerals. Shipments average fifteen million pounds of ore a week. Located about 75 miles due south of Salt Lake City on the Denver and Rio Grande or Salt Lake Route, or can be reached by automobile. Representatives of the Utah Power and Light Company will welcome all visitors and conduct them on inspection. Fare: railroad—approximately $9.00. Time required: two days. Fare: automobile—about $25.00 for the trip. Time required: one day.

Carbon County Coal Mines. 6,000,000 tons of high grade bituminous coal mined in this field in 1920. Interesting feature of this field is that instead of using steam electric power produced

SOUTH TEMPLE STREET, SALT LAKE CITY

from their own coal the mining Companies find it economical to purchase hydroelectric power for their mining operations. The mines are located 125 miles south of Salt Lake City and reached by the main line of the D. &. R. G. Ry. Railway fare, $13.74 round trip. Time about one and one-half days.

Mills and Smelters. If you are interested in seeing how ores are smelted and refined and have but a limited amount of time available, a short visit to either the United States Smelting Refining and Mining Company's smelter at Midvale, or the American Smelting and Refining Company's smelter at

Murray will be worth while. Both smelters can be reached by street cars which pass Convention headquarters. Cost of trip $2.00. Time required: one day.

Salduro—Potash Works. On the Great Salt Lake Desert, 100 miles west of Salt Lake City is a potash industry, a subsidiary of the Solvay Process Co. It is located on the main line of the Western Pacific Railroad and if you are going through to California over this road, you may be interested in stopping off one day to see it. It is a two day trip to see this industry and return to Salt Lake City. You will be taken care of over night at Salduro at nominal cost and can look over the process and return to Salt Lake City the next day. Total cost of trip, approximately $20.00.

Zion National Park, Cedar Breaks, Grand Canyon National Park and Bryce Canyon. A ten day scenic trip, magnificent in extent, has been arranged which takes in Zion

Bingham Copper Mines

National Park, Cedar Breaks, the North Rim of the Grand Canyon and Bryce Canyon, a new and unexplored country. If time is not available shorter trips can be made to any one or two of the above points of interest.

Round trip tickets for the popular "all Expense Tours," via National Park Transportation & Camping Company service, include all auto transportation and all meals and lodgings en route.

Zion and Grand Canyon Parks, Cedar Breaks and Bryce Canyon, 10 days, $140.00 per person.

Brighton Resort. (Big Cottonwood Canyon). One of the most inspiring touring trips to the heart and tops of the Wasatch range, southeast from Salt Lake City, is that to Brighton Resort, 36 miles from the city by automobile through Big Cottonwood Canyon. Here is a mountain locked retreat of striking and unusual beauty, one of the best for midsummer rest, recreation, and study. The altitude is 8600 feet. Accommodations at this charming Alpslike retreat are provided at the Brighton Hotel and the Balsam Inn, including lodgings and meals. The round trip fare from Salt Lake City will be $4.00 during the A. I. E. E. Convention.

MOUNTAIN CLIMBS

Those who feel the "Call of the Wild" will be able to satisfy it, for the Wasatch Mountains are almost at the door of the Hotel. All sorts of "climbs" and "hikes" are available, long cimbs, short ones and intermediate. If visitors will make their desires known at the Bureau of Information, full directions will be given and arrangements made for any kind of a climb or "hike" desired.

A. I. E. E. DIRECTORS MEETING
MAY 20, 1921.

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Friday, May 20, 1921.

There were present: President A. W. Berresford, Milwaukee; Past-Presidents C. A. Adams, Calvert Townley, New York; Vice-Presidents Charles Robbins, Pittsburgh, L. T. Robinson, C. S. McDowell, Schenectady; Managers Walter A. Hall, Boston. Wm. A. Del Mar, W. I. Slichter, L. F. Morehouse, E. B. Craft, New York, G. Faccioli, Pittsfield, F. D. Newbury, Pittsburgh, Harold B. Smith, Worcester; Treasurer George A. Hamilton, Elizabeth, N. J.; Secretary F. L. Hutchinson, New York. Present by invitation, William McClellan, of Philadelphia.

Approval by the Finance Committee of monthly bills amounting to $21,391.57 was ratified. The annual report of the auditors was presented.

Annual reports of the Board of Directors, the Treasurer, and of standing committees, were presented and accepted.

A report was presented of the Board of Examiners covering its meeting held May 13, 1921; and the actions taken on applications at that meeting were approved. Upon the recommendation of the Board of Examiners the following action was taken upon pending applications: 195 Students were ordered enrolled; 237 applicants were elected to the grade of Associate; 21 applicants were elected to the grade of Member; 19 applicants were transferred to the grade of Member.

The Meetings and Papers Committee reported upon plans in progress for the Annual and Pacific Coast Convention, at Salt Lake City, June 21-24, and presented a recommendation that the October meeting be devoted to the subject of lightning protection, under the auspices of the Protective Devices Committee, with the location of the meeting probably at Philadelphia. The Committee further reported that in connection with the joint meeting with the Society of Naval Architects and Marine Engineers to be held on the afternoon of November 17, 1921, a lecture will be given in the evening of the same day by Professor A. N. Goldsmith, on "World Communication." The report of the Committee was accepted.

Authority was granted for the organization of a Student Branch at Swarthmore College, Swarthmore, Pa.

The required procedure for amending the by-laws having been complied with, the Board voted to amend Section 44 of the by-laws to read as follows:

> Sec. 44. Reprints of any paper published by the Institute not exceeding 50 copies, will be furnished without covers, free of charge, for the personal use of the author if requested within thirty days after publication. Special covers will be charged for at cost.
>
> For reprints in excess of 50 copies, or when ordered later than specified above, a charge will be made.

The appointment of a Secretary for the year beginning August 1, 1921, was considered in accordance with Section 37 of the Constitution; Secretary F. L. Hutchinson was reappointed.

Upon the recommendation of the Chairman of the Committee on Economics of Electric Service, the Board voted to discontinue this committee at the close of the present administrative year, and directed that the necessary steps be taken to amend the by-laws accordingly.

Approval was given to the admission of the American Institute of Architects to membership in the American Engineering Standards Committee.

An invitation from the Society for the Promotion of Engineering Education, was accepted, to send a delegate to the annual meeting of that Society, June 28-July 1, 1921; and the President was authorized to appoint a delegate.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the Journal under suitable headings.

ANNUAL MEETING

ELECTION OF OFFICERS

The Annual Meeting of the A. I. E. E. was held in the Engineering Societies Building, New York, on Friday evening, May 20, 1921, President Arthur W. Berresford presiding.

The annual report of the Board of Directors was presented in abstract by Secretary Hutchinson. Pamphlet copies of this report had been printed in advance and are available to any member upon application to the Secretary of the Institute.

The report of the Committee of Tellers on the election of officers was then presented (printed elsewhere in this issue) and in accordance therewith, President Berresford announced the election of the following officers, whose terms will begin August 1, 1921: *President*, William McClellan, Philadelphia, Pa.; *Vice-Presidents*, Walter A. Hall, Boston, Mass.; N. W. Storer, Pittsburgh, Pa.; William A. Del Mar, Yonkers, N. Y.; C. G. Adsit, Atlanta, Ga.; John C. Parker, Ann Arbor, Mich.; F. W. Springer, Minneapolis, Minn.; H. W. Eales, St. Louis, Mo.; Robert Sibley, San Francisco, Cal.; O. B. Coldwell, Portland, Ore.; F. R. Ewart, Toronto, Ont.; *Managers*, A. G. Pierce, Pittsburgh, Pa.; R. B. Williamson, Milwaukee, Wis.; Harlan A. Pratt, New York, N. Y.; *Treasurer*, George A. Hamilton, Elizabeth, N. J.

The above, together with the following hold-over officers, will constitute the Board of Directors for the next administrative year: A. W. Berresford, Milwaukee, Wis.; Calvert Townley, New York, N. Y.; Walter I. Slichter, New York, N. Y.; G. Faccioli, Pittsfield, Mass.; Frank D. Newbury, Pittsburgh, Pa.; L. E. Imlay, New York, N. Y.; F. F. Fowle, Chicago, Ill.; L. F. Morehouse, New York, N. Y.; Harold B. Smith, Worcester, Mass.; James F. Lincoln, Cleveland, Ohio; E. B. Craft, New York, N. Y.

The wide geographical distribution of the Institute's Directors is indicated by the fact that thirteen states and Canada are represented in the above list.

REMARKS OF PRESIDENT-ELECT McCLELLAN

At the close of the business session President Berresford introduced President-Elect William McClellan, who spoke as follows:

It would be really a very strange man who would not be very happy, yes, and somewhat set-up at this time when such a very great honor is announced to him. After having worked along for a great many years with the men of an Institute like this, brother professional men, and then after these years to have been chosen to occupy this office of president, which has been held by so many prominent and worthy men, is about as great an honor as could come to any professional man.

At times like this I have sat in the audience and heard men say they had a feeling of humility, and all they asked for was to be able to do as well as their predecessors had done, and sometimes I might have slightly questioned their sincerity; but I assure you that tonight, when it comes to this position and I am faced with the responsibility of this very great office at the head of this wonderfully noble profession, there is a feeling of humility, and one does look at the work of his predecessors almost with awe, and wonders if by any possibility he can measure up to it.

But then right in the same moment comes a great feeling of buoyancy, especially just now, when we look forward and see what is to be done, because it is going to be a great year; and when we see and think of the great things that are facing the profession of engineering—and electrical engineering has certainly played its part among the leaders; when we look at the great movements taking place in which this profession is interested and concerned, they seem almost endless.

I have in mind that during the year, largely under the inspiration of one of our past-presidents, we have been able to get this new American Engineering Council working to take care of the interests of the profession, and to take care of the public welfare, so far as engineers can help in it. I see, through the leadership of that great engineer, Herbert Hoover, The Federated American Engineering Societies pointing the way to greater and greater work for the profession to accomplish, giving it a new vision, giving it a point of view which it never has had before.

Then, due to the war, I see opportunities for this profession, and they are many. Take the railroad situation, appalling as it is in this country today. Think of this great country with all its natural resources, with all its agricultural and mechanical and mining and manufacturing wealth. And then to see these great public utilities struggling, to see the great public not understanding their real function among us, that is, as facilities lying at the very basis of all our business. Without the railroads, without the power companies, without the electric railways, gas companies, telephone companies, water companies, and others, it would be utterly impossible in these times to conduct business, and as they are strong and able to function, so business will march forward, strongly and powerfully.

Then we are talking of reorganizing the government, and it is the purpose of engineers to play their part in connection with that. Further we have this great question of foreign trade, because we have passed in this country (and those engineers among you here that are connected with manufacturing plants know it), from the time when foreign trade was more or less of a luxury for a few people, to the time when it is the foundation of our prosperity. Someone has figured that the domestic demand in this country would not take over 70 per cent of the average of the productive capacity of the country, and if we worked to the potential productive capacity of the country, no one knows how much foreign trade and commerce we could supply.

We are not ready for it, and have not the facilities. One of the things we must do is to put a large number of foreign buyer

on their feet; for while we have magnificent national facilities for the buyer on his feet, we have none for those who are not on their feet. That work applies to the banker, but there is a side of engineering to it; as the bankers have said the risks are too great for them to sift out the weak from the strong, which is the work of the engineer, and no one can do it better than the engineer. We must turn our eyes to foreign trade and foreign commerce. It is our business; and we must assist in the formation of a great investment bank, that corresponds in foreign trade to what we call the investment banker in this country, in order to put that foreign buyer on his feet, so that he can buy from us and increase our prosperity and put our whole productive capacity to work.

Then you come back to the definition of what an engineer is—a man who can make one dollar do scientifically, according to engineering principles, what it would take $10.00 to do otherwise, and one man to do what it would ordinarily take ten men to do, etcetera. In this country of prosperity we must do things, and the engineer has a tremendous share in that great task, brought on partly by the war, more I think discovered by the war than brought on or caused by it, although one cannot deny our greatly increased productive capacity is largely due to it. Now, I say under these circumstances we need men. If engineers were called on today to solve this great immigration problem that seems to be worrying the country, I do not think they would turn back these immigrants, these able-bodied, fine, strong men and women, brought up to manhood and womanhood and ready to come here to work—they are worth a huge number of dollars to us. I think we would find some way of getting them into the country. We might establish ports of entry in the West, so that they could not stay here in New York; or if we selected them on the other side, that would be an engineering method; and then put them where they are needed, that would also be an engineering method; and the engineering genius of this country has to be applied to the problem before we can hope to succeed in having the prosperity we dream of. And as I look forward to the coming year, my only hope and prayer is that we all can play our part, small or great, as it may be, in this great task of rendering America prosperous.

LECTURE BY DR. ALBERT W. HULL

President Berresford then introduced Dr. Albert W. Hull, of the Research Department of the General Electric Co., who delivered a lecture on "The Magnetron—A New Electric Valve." The lecture was illustrated by numerous lantern slides and experimental demonstrations. It will be published in a future issue of the JOURNAL.

After a rising vote of thanks to Dr. Hull, the meeting adjourned.

REPORT OF COMMITTEE OF TELLERS ON ELECTION OF OFFICERS

To the President,
American Institute of Electrical Engineers.

DEAR SIR:

This committee has carefully canvassed the ballots cast for officers for the year 1921-1922. The result is as follows:

Total number of ballot envelopes received		4651
Rejected on account of bearing no identifying name on outer envelope, according to Art. VI, Sec. 34, of the Constitution	50	
Rejected on account of voter being in arrears for dues on May 1, 1920, as provided in the Constitution and By-laws	99	
Rejected on account of ballot not being enclosed in inner envelope, or being improperly marked, or on account of inner envelope bearing an identifying name, according to Art. VI, Sec. 34, of the Constitution	145	
Rejected on account of having reached the Secretary's office after May 1, according to Art. VI, Sec. 34, of the Constitution	19	313
Leaving as valid ballots		4338

These 4338 valid ballots were counted, and the result is shown as follows:

For President

The scattering votes referred to in this report are shown in records of the committee deposited at Institute headquarters.

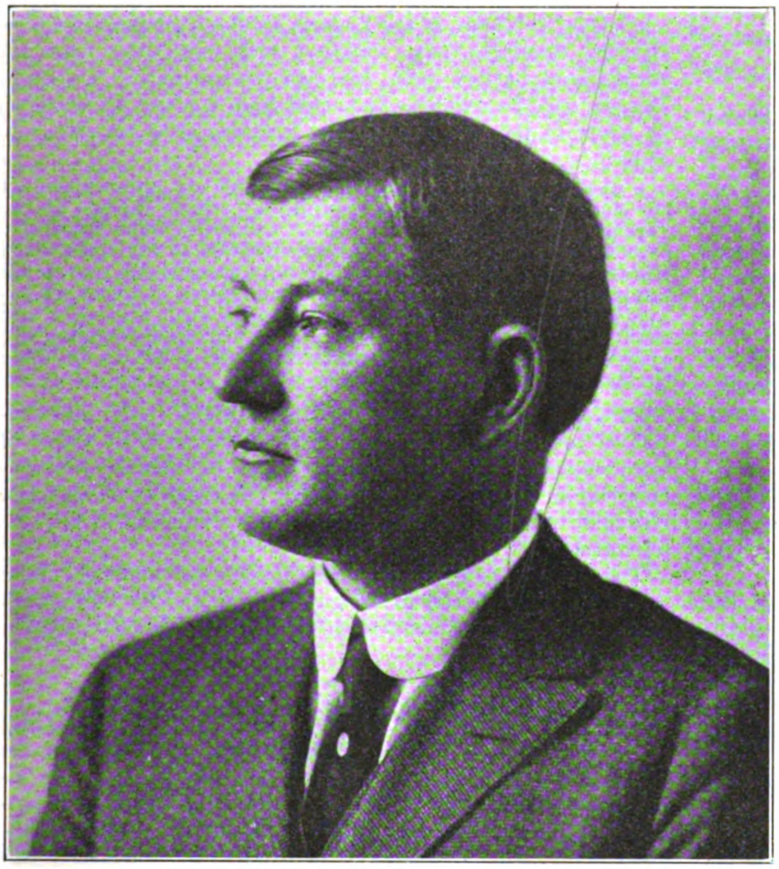
Respectfully submitted,
E. A. SKEHAN,
(*Signed*) JOHN D. POLLOCK
W. W. VERNON
CLYDE DRAKE,
WM. E. SEAMAN.

May 13, 1921. *Committee of Tellers.*

WILLIAM McCLELLAN
President Elect of A. I. E. E.

Dr. William McClellan has been elected President of the American Institute of Electrical Engineers for the year beginning August 1, 1921, as announced in the report of the annual meeting published elsewhere in this issue.

Mr. McClellan is a Philadelphia man by birth and education. He was graduated from the University of Pennsylvania in 1900 with the degree of B. S. and later with the degree of Ph. D., and in 1913 received the degree of E. E. After his graduation he was employed with the Philadelphia Rapid Transit Company engaged in all forms of railway and construction work, and became engineer in charge of construction. He left in 1905 to go to New York, with Westinghouse Church, Kerr and Company, and was later one of the managing engineers of this firm engaged in electrification and work on the railway terminals and tunnels. In 1907 he became associated with H. T. Campion of Philadelphia, in construction engineering, which association has been maintained to date, the present firm, McClellan and Campion, having offices in New York City and Philadelphia.



WILLIAM McCLELLAN
PRESIDENT ELECT A. I. E E

Mr. McClellan was for three years electrical engineer and Chief of the Division of Light, Heat, and Power of the Public Service Commission of New York State, Second District. Sometime after resigning from this work he organized and managed the rate investigation of the New York Telephone Company for the Commission.

Just before the war he was appointed Dean of the Wharton School of Finance and Commerce of the University of Pennsylvania, and remained there until 1919, when he became Vice-President of the Cleveland Electric Illuminating Company. During the war he was Director of the Intercollegiate Intelligence Bureau in Washington, an association of all the principal colleges of the United States to assist the government in obtaining trained men.

President-Elect McClellan has been active in Institute affairs. He first joined the Institute in 1904, was transferred to the grade of Member in 1909, and became a Fellow in 1912. He has been Manager and Vice-President of the Institute, and has served on various committees. He has also contributed valuable papers and discussions at meetings. He is a member of the American Society of Mechanical Engineers, of the American Society of International Law, the American Economic Association, the Academy of Political Science in the City of New York, the American Political Science Association, the Merchants' Association of New York, the American Gas Institute, and is at present a member and Chairman of the Finance Committee of the Executive Board of the American Engineering Council. His various society activities as well as his engineering experience well fit him to take up his duties as President of the American Institute of Electrical Engineers, and he brings to that office a broad vision and high ideals, coupled with executive ability, which will keep up the standards of the Institute.

BRADLEY STOUGHTON RESIGNS AS SECRETARY OF A. I. M. E.

Mr. Bradley Stoughton tendered his resignation as Secretary of the American Institute of Mining and Metallurgical Engineers, to the members of the Board of Directors of that Institute, on May 17, 1921. Mr. Stoughton expressed his reasons by his belief, as indicated to the president and some members of the Board two years ago, that the office of Secretary should not be a permanent one; but at that time he was persuaded to defer resignation until a more convenient time for the Institute. He feels that this time has now arrived. The Board of Directors accepted with regret Mr. Stoughton's resignation, expressing its appreciation of his long and efficient service to the Institute, and of the self-sacrifice with which he has devoted himself to the interests of the organization at the expense of his own professional choice or financial advantage. He became Secretary of the A. I. M. E. in 1912, and since that time the Institute has greatly increased in membership and in activities. Mr. Stoughton has offered to remain in his present office for a reasonable time, to assist his successor, when appointed, in familiarizing himself with the details of the work.

A. I. E. E. 1921 STANDARDS

A new edition of the Standards of the A. I. E. E. has been published and is now available for distribution. This edition which bears the date 1921 has been completely revised in form by the Standards Committee, under the direction of chairman L. T. Robinson, in order to correct some inherent defects in the form of the earlier editions, and to better adapt it to receive the additions which are made from time to time.

A number of changes in substance has been made and some new sections have been added in the new edition, which also contains the International Electrotechnical Commission rules for electrical machinery, adopted in 1919.

The book contains 172 pages 6 by 9 in., flexible cloth binding, price $2.00. (Discount of 25 per cent to Institute members.)

AMERICAN ENGINEERING COUNCIL

NATIONAL PUBLIC WORKS DEPARTMENT

American Engineering Council has announced that it would start a nationwide campaign for the establishment of a National Department of Public Works.

It will take over the entire machinery of the National Public Works Department Association, organized in Chicago in 1919 to bring about the reorganization of the Department of the Interior by the establishment of a National Department of Public Works. Senator Reed Smoot of Utah and Representative C. Frank Reavis of Nebraska, sponsors of the original public works legislation, are now leading in the movement for general government reorganization which, the engineers say, was largely inspired by the activity for public works reform.

Upon the recommendation of its Committee on Public Affairs, Council has officially determined that it will not concern itself with the general reorganization activities of the government, but will confine its efforts to the engineering and allied aspects of the Smoot-Reavis Committee program. This view, it was said, was shared by Herbert Hoover, who retired as president of Council. Adoption of a clear attitude on public questions was one of the last acts of Mr. Hoover's regime as head of Council.

At a meeting to be held in St. Louis on June 3, and which will be attended by engineers from many cities, Council will consider an elaborate plan for renewing the public works campaign in every state. The old public works state organizations will work in harmony with American Engineering Council under the general direction of L. W. Wallace, executive secretary of Council.

FOREIGN RELATIONS COMMITTEE

American Engineering Council has organized a Foreign Relations Committee with L. B. Stillwell of New York as chairman. Discrimination against American patents in Europe, the Council announces, has ceased as a result of the passage of the Nolan Treaty Patent Bill on March 3. The Patents Committee of Council had previously reported that American inventors were at a great disadvantage in foreign countries because of the lack of proper legislation. Council urges the passage of pending patent legislation to increase salaries in the United States Patent Office which is being crippled by wholesale resignations. The Patent Office, it was said, faces disorganization if remedial legislation is not enacted at the present session.

VISITING MEMBER PRIVILEGES WITH FOREIGN ENGINEERING SOCIETIES

The attention of the membership of the Institute is again called to the fact that several years ago, namely, in 1912 during the administration of President Gano Dunn, arrangements were made with several of the foreign Engineering Societies, entitling visiting members of the American Institute of Electrical Engineers to the privileges of membership in the Societies concerned for a period of three months, and foreign members visiting the United States are accorded corresponding privileges of Institute membership for a like period.

The underlying purpose of the formulation of this plan was the promotion of closer relations between the Institute and foreign Electrical Engineering Societies.

The Societies with which this arrangement is at present in force are as follows:

Institution of Electrical Engineers (Great Britain)
Societe Francaise des Electriciens (France)
Associazione Elettrotecnica Italiana (Italy)
Koninklijk Instituut van Ingenieurs (Holland)
Association Suisse des Electriciens (Switzerland)
Denki Gakwai (Japan).

There has been prepared for the use of Institute members while abroad a form of certificate which will serve as credentials from the Institute to foreign Societies. Any Institute member in good standing intending to go abroad may obtain such certificates upon application to the Secretary of the Institute, a separate certificate being furnished for each foreign Society.

Prof. A. R. Nissar, of the Victoria Jubilee Technical Institute, Byculla, Bombay, India, obtained such certificates from Institute headquarters some time ago for use during a visit to Europe, and the following is quoted from a recent letter which he wrote to the Secretary of the Institute after his return to India:

> I also take the opportunity to express my appreciation of the courtesies extended to me during my trip to Europe by the various sister Institutions in those countries, more especially France and Switzerland, on the presentation of my credentials, without which it would have been impossible to secure the numerous visits to places of electrical interest. I had an enjoyable and most instructive trip through such courtesies and shall be greatly obliged to you if you will kindly express my appreciation through the columns of the A. I. E. E. JOURNAL to the various sister Institutions of Europe.

Foreign engineers visiting the United States, upon presentation of proper credentials, are often furnished with letters of introduction to Institute members and to officers of manufacturing and operating companies. The facilities at Institute Headquarters, including the Library, are also accorded to visiting members.

The visiting member privileges involve no expense, either to Institute members or to foreign members, and the advantages which they offer commend them to the favorable consideration of the membership.

ROCHESTER ENGINEERS MEET

The engineers of Rochester participated in a joint dinner on May fifth, at the Powers Hotel, in which the following societies took part: American Association of Engineers, American Institute of Electrical Engineers, American Legion—Engineers' Post, American Society of Mechanical Engineers, Rochester Engineering Society, Rochester Society of Architects, and Rochester Society of Technical Draftsmen. Calvert Townley of the A. I. E. E., and first vice-president of the Federated American Engineering Societies, was the principal speaker of the evening. In his talk Mr. Townley prescribed a cure for business depression, saying that we must stimulate world trade by restoring the foreign markets. Putting the present stagnation of industry and commerce as due to the breaking down of our export trade, he suggested as a remedy the buying up of the most promising of European industries by American capital, and their operat on under American management, providing work at food wages for European labor, so as to create general prosperity on the other side of the water and thus restore normal purchasing power. In the meantime, he pointed out, the securities of the industries taken over, could be converted through the banks into American securities, enabling the promoters, with good management, to make a profit at both ends of the line, and at the same t me performing a valuable service to the country by creating an adequate outlet for surplus American products.

Other speakers were: W. Roy McCanne, president of the Rochester Chamber of Commerce, and Charles C. Evans,

president of the Rochester Society of Architects, who were introduced by John A. Robertson, of the Eastman Kodak Company, as toastmaster. Entertainment was provided by John P. Day, comedian, and Jesse B. Millham, song leader.

PAGEANT OF PROGRESS EXPOSITION

CHICAGO, JULY 30 TO AUGUST 14

The Pageant of Progress Exposition, to be held on Chicago's $5,000,000 Municipal Pier, July 30th to August 14th, 1921, will present a panorama of industrial progress, promising to be one of the greatest exhibits in years. One of the features will be electricity shown in all its variety of applications, and visitors to the exposition will see for the first time a complete history of the development and use of electricity.

The exhibits are being planned to tell the story of electricity in a picturesque manner. One sub-section, consisting of a series of six booths, will be devoted to the miniature representation of electric transportation. On the floor space of this section there will be full sized electric vehicles. Directly above these exhibits will be a panoramic painting, one hundred and forty feet in length, showing some scenes along the right of way of the Elevated and North Shore Electric roads, with a tiny model train in constant operation along the pictured track. Above this painting with its miniature train, will be a second painting. This will have scenes taken from along the right of way of one of the transcontinental railroads which has been electrified in part. This painting, which will also be one hundred and forty feet in length, will show miniature power houses, waterfalls, and tunnels, and there will be several model electric trains which run along this route and through the tunnels, operating continuously.

The story of lighting will also be told in an interesting fashion, and several surprising exhibits will be shown to illustrate the remarkable changes which take place due to lighting effects. These exhibits have been developed as a result of many interesting laboratory experiments. The many features will be so all-inclusive that it will take a day to see just the electrical exhibit alone in its entirety.

AMERICAN ENGINEERING STANDARDS COMMITTEE

CONFERENCES ON STANDARDIZATION

In compliance with a joint request from the American Institute of Architects and the National Association of Electrical Contractors and Dealers, the American Engineering Standards Committee held a conference in New York, on May 10th, to which representatives of all interested national organizations were invited, for the purpose of adopting a program looking toward the establishment of national symbols for electrical equipment in buildings. It was decided to ask the American Institute of Electrical Engineers, the National Association of Electrical Contractors and Dealers, and the American Institute of Architects to become sponsors for a sectional committee to deal with this subject. It was brought out at the conference that electrical equipment for buildings on land and afloat should be considered the same, and this ruling was adopted. Thus electrical equipment for ships will be included with that for other buildings.

The Bureau of Standards and the Society of Automotive Engineers, which have agreed to act as joint sponsor for a Safety Code for Aeronautics, called a conference in Washington, D. C., on May 13th. Representatives of interested national organizations were invited, to consider the scope of the proposed code, the method of its development, and the make-up of the sectional committee to be organized. This committee is now being organized under the sponsorship of the Bureau of Standards and the Society of Automotive Engineers.

STANDARDS RECENTLY APPROVED

Standards recently approved by the American Engineering Standards Committee include the following:

Submitted by the American Society for Testing Materials as Tentative American Standards:

5-1921 Standard Method for Distillation of Bituminous Materials Suitable for Road Treatment.

6-1921 Standard Method for Sampling of Coal.

7-1921 Standard Test for Toughness of Rock.

The Committee has also approved as American Standard the following code submitted by the National Fire Protection Association:

8-1921 National Electrical Code.

PERSONAL MENTION

H. R. Noack of the Pacific States Electric Company has been elected vice-president of the company.

John P. Rockwood has changed his business address from 95 Liberty Street to 71-73 West Broadway, New York City.

Frank V. Burton has left the Bryant Electric Company, Bridgeport, Conn., and is now sales manager for Henry D. Sears, Boston.

Kay A. Christiansen has left the Federal Telegraph Co., Palo Alto, Cal., to locate with the Pacific Tel. & Tel. Co., San Francisco, Cal.

F. Hymans, who was with the Otis Elevator Company, is now located with the Vibration Specialty Company, 303 Harrison Bldg., Philadelphia.

John E. Kelly, formerly of Humboldt, Tenn., is now resident manager of the Honduras Henequen Co., Inc., at Tegucigalpa, Republic of Honduras.

Harry W. Motter, of George F. Motter's Sons, York, Pa., announces the removal of the firm's office and storeroom to 335 West Market Street.

H. W. Hough, formerly with the Daniel M. Leuhrs Co., Cleveland, Ohio, is now with the Cleveland Electric Illuminating Co. as research engineer.

P. H. Chase has severed his connection with the American Railways Company, Philadelphia, and is now with the Philadelphia Electric Company.

J. R. Cravath has recently become president of the Pioneer Electric Company, electrical engineers and contractors, of Richmond, Cal.

J. P. Fish, who was with Stone & Webster, Boston, will be Located in India, with The Angus Company, Ltd., No. 3, Clive Row, Calcutta, India.

Harold C. Smith, formerly with the Iowa Telephone Company, Des Moines, Iowa, is now with the N. W. Bell Telephone Company, Fargo, North Dakota.

Jerome Blaisdell has left the Commonwealth Electric Co., Summit, N. J., and is located with The Depew & Lancaster Light, Power & Conduit Co., Lancaster, N. Y.

Chas. C. Allen, formerly with Dwight P. Robinson & Co., Inc., New York, is in Dallas, Tex., with the W. C. Hedrick Construction Co. Mr. Allen is vice-president of the company.

J. Ludwig Hansen, formerly of St. Anthony, Idaho, has moved to Salt Lake City, where he has established an office as consulting electrical engineer, in the Utah Saving & Trust Building.

W. L. Laing has changed from the Shepard Electric Crane & Hoist Co., Montour Falls, N. Y., to the Champion Engineering Co., of Kenton, Ohio, where he is superintendent of service and erection.

Charles F. McLaughlin has resigned as manager, Service Engineering Department, Kentucky Actuarial Bureau, and is now special agent at Bellefontaine, Ohio, for the Continental Insurance Company.

David D. Gibson, Jr., formerly with Stone & Webster Corporation as a designer, is now located with the Y. M. C. A. Extension School of New York City as associate head of the Electrical Department.

Charles H. Keel, formerly of the General Electric Company and of the Curtiss Aeroplane Corporation, has opened an office at 15 Park Row, New York City, for the practise of patent and trade-mark laws.

F. F. Burroughs, with the Mutual Fire Prevention Bureau, formerly located at Oxford, Mich., announces the removal of the bureau to 230 East Ohio St., Chicago. Mr. Burroughs is one of the managers of the bureau.

C. H. Shepherd, formerly electrical engineer in charge for the Commissioners of Lincoln Park, Chicago, has entered private practise as a consulting engineer specializing in street-lighting and general power-system engineering.

George C. Dean, of Dean, Fairbank, Obrieght & Hirsch, announces the removal of the firm's offices to 15 Park Row Building, New York City, where the practise of patent, trade-mark and corporation law will be continued.

R. S. Daniels, for fifteen years with the Washington Water Power Company of Spokane, Washington, has left for Berkeley, Cal., to take a position as assistant to the chief engineer of the California-Oregon Power Company of San Francisco.

Edmund J. Henke is now president of the American Electric Fusion Corporation, Chicago, recently organized, manufacturers of electric welding apparatus. Mr. Henke has been engaged in this field for a number of years.

Charles H. MacDowell was elected president of the Western Society of Engineers at the election held May 4th. Mr. MacDowell is president of the Armour Fertilizer Works, and brings to this position a wide experience as an executive.

Hartley Rowe, manager of the Detroit office of Lockwood Greene & Co., Engineers, has been transferred to Boston, as district manager of the Boston office, succeeding Kenneth Moller who was recently elected into the firm of Lockwood, Greene & Co.

Frank Sawford, formerly chief engineer of the Taylor Engineering Company, Ltd., Vancouver, B. C., has opened an office at 609 Credit Foncier Building, Vancouver, as consulting and constructing mechanical and electrical engineer, specializing in industrial power plants.

George Smith has been made president and general manager of the Vim Electric Company, Inc., of New York City, specializing in electric power equipment. Mr. Smith was formerly associated with the General Electric Company for eighteen years altogether, ten years of which were spent at the Sprague Electric Works as commercial engineer, and as manager of motor and generator sales.

F. H. Wilkins, European general manager of the International Western Electric Company with headquarters in London, has been elected a vice-president of his company. Mr. Wilkins entered the employ of the Western Electric Company forty years ago, eventually becoming manager of its New York branch. In 1910 he went to Europe to look over foreign trade conditions and a year later was made European general manager of his company.

Ira Cushing is now associated with The Condit Electrical Mfg. Co., South Boston, Mass., as a sales specialist, paying particular attention to circuit breakers, switchboards, and switching arrangements. Mr. Cushing had been with the General Electric Co. for more than eighteen years up to last year, when he was sales-engineer representing the Three-E Co., in New England. He is at present secretary-treasurer of the Boston Section of the Institute.

William S. Lee, vice-president and chief engineer of the Southern Power Company, Charlotte, N. C., has been elected president of the Piedmont & Northern Railroad, to succeed the late Z. V. Taylor. Mr. Lee has been connected with engineering construction in the South for nearly twenty-seven years, and has been a leader in the electrification of industries there. He has been vice-president of the Piedmont & Northern Railroad, which takes power from the Southern Power Company's system.

M. O. Leighton has been appointed director of the south-eastern branch of the Engineering Business Exchange, New York City, with offices in the McLachlen Building, Washington, D. C. The exchange conducts the purchase and sale of engineering and technical business properties. Mr. Leighton was for the past three years active in the work of Engineering Council being chairman of the National Service Committee. A. C. Oliphant, who was also a member of the National Service Committee of Engineering Council, will be associated with Mr. Leighton in the exchange.

F. M. Feiker of New York, vice-president and chairman of the editorial board of the McGraw-Hill publications, has been appointed as personal assistant to Mr. Hoover, his duties to consist of organizing and developing those branches of the Department of Commerce which relate directly to commerce and industry. Mr. Feiker has actively aided Mr. Hoover along other lines, having been a central figure in the movement with Mr. Hoover and the heads of engineering societies to enlist engineers in the problems of public service which resulted in the formation of the Federated American Engineering Societies, from the presidency of which Mr. Hoover has just retired; and being of aid in the development of the plan for the elimination of waste in industry, which was undertaken at Mr. Hoover's suggestion. He is a graduate of the Worcester, Mass., Polytechnic Institute, class of 1904, and an electrical engineer by profession.

OBITUARY

JOEL E. ANDERSON, of Joliet, Ill., died on April 2, 1921, following an operation. Mr. Anderson was born in Joliet, January 11, 1892, and received his early education there, later entering the Armour Institute of Technology, from which he was graduated in 1917. He then continued work with the Sanitary District of Chicago at the hydroelectric plant at Lockport, where he had been engaged part of the time during his college course, until April, 1918, when he enlisted in the army to serve during the war. After the war he was employed by the Cline Electrical Manufacturing Company, Chicago, and remained with that company until his death. Mr. Anderson was an Associate of the INSTITUTE.

WILLIAM A. LYNN, of Vallejo, Cal., died at San Francisco, April 10, 1921. Mr. Lynn was born near Salinas, Cal., October 5, 1873, and was graduated from the College of Mechanics, University of California, in 1897. During the next year he had charge of the University of California electric light station, and then became an instructor of Electrical Engineering in the university, leaving in 1902 to take a position with the San Jose and Santa Clara railroad. In 1908 Mr. Lynn was appointed to the position of expert electrical aid at the U. S. government yard at Mare Island, which position he held at the time of his death. His service was largely that of a consulting engineer, and his advice in engineering matters was continually sought by his associates. Mr. Lynn made many friends, particularly among the younger men, to whom he offered his personal interest and advice. He had been an Associate of the INSTITUTE since 1899.

WILLARD L. CANDEE, one of the pioneers in the telephone field, died suddenly on April 24, 1921. Mr. Candee was born in Yonkers, N. Y., March 28, 1851, and became interested in the telephone when it was still a novelty. He did much toward making its use popular, a telephone line which he built in Brooklyn between his boarding house and his father's residence being one of the first in that city. His range of engineering experimental work included arc lighting, telegraphing from a moving train, and the protection of exposed wires. Mr. Candee was connected with several of the older electrical companies in New York, having helped to organize the Jablochkoff Electric Light Company and the Telephone Company of New York, both of which were later sold. In 1884 he organized with Mr. Charles A. Cheever the Okonite Company, Ltd., of which he served as president for a number of years. Mr. Candee was formerly Captain of Company D of the Twenty-third Regiment of the National Guard of New York State, and belonged to the Montauk Club, the Brooklyn Riding and Driving Club, the Lotos Club of New York, and was a prominent Freemason. He joined the INSTITUTE in 1904.

EDWARD BENNETT ROSA, chief physicist of the United States Bureau of Standards, died suddenly in his office on May 17th.

Dr. Rosa has done notable work in electrical research. He was born in Rogersville, New York, Oct. 4, 1861. After his graduation from Wesleyan University, Middletown, Conn., in 1886, he entered Johns Hopkins University, Baltimore, and received the degree of Doctor of Philosophy. After serving as an instructor at the University of Wisconsin and as Professor of Physics at Wesleyan he became chief physicist of the Bureau of Standards in 1901.

One of his first achievements was to develop the physical side of the respiration calorimeter with Professor W. O. Atwater at Wesleyan. This apparatus was of great value in the pioneer investigations of the value of foods.

With Dr. Dorsey as collaborator Dr. Rosa in 1907 began work on the determination of the ampere. With Dr. Grover he collected practically all the known formulas for computing induction. This collection is known throughout the world as a model.

Another achievement was to definitely establish the laws governing electrolytic corrosion, a problem of major importance to public utility companies operating underground gas and water pipes and electric railways.

In the World War Dr. Rosa developed a number of scientific instruments of great value to the American forces in France. Among these were a sound ranging device for locating big guns, the geophone for detecting mining operations, the development of aircraft radio apparatus and the improvement of radio direction finders by which enemy ships and aircraft could be located. Under his direction the Bureau of Standards has established what is perhaps the finest radio research laboratory in the country. Dr. Rosa also perfected devices to insure safety devices in industrial plants.

Dr. Rosa has served as a member of the Standards Committee of the American Institute of Electrical Engineers; and of the Committees on Papers, and Nomenclature and Standards, as chairman of the Research Committee and as a director of the Illuminating Engineering Society; and he has been a very active worker for the American Engineering Standards Committee. At the time of his death he was an official representative of the Illuminating Engineering Society on the Governing Board of the American Association for the Advancement of Science; a Fellow of the American Institute of Electrical Engineers; a member of the U. S. National Committee of the International Electrotechnical Commission; a member of the main Committee of American Engineering Standards Committee as a representative of the U. S. Department of Commerce and a member of the Executive Committee; chairman of the Rules Committee, and chairman of the National Safety Code Committee of the A. E. S. C. In addition to the organizations just named he was a member of the National Academy of Sciences, American Philosophical Society, American Association for the Advancement of Science, the American Physical Society, the Societe de Francaise de Physique, the Washington Academy of Sciences, the Philosophical Society of Washington, and was secretary of the International Committee on Electrical Units and Standards.

He has been the recipient of the Elliott Cresson medal of the Franklin Institute.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Leo Arany, Room 201 Parkway Bldg., Broad & Cherry Street, Philadelphia, Pa.

2.—Paul H. Butler, Pittsburgh Transformer Co, 30 Church St., New York, N. Y.

3.— DeLos De Tar, 411 East 15th Street, Kansas City, Mo.

4.—Harry Dowling, 425 South Street, Pottstown, Pa.

5.—George W. Huey, R. F. D. No. 5, Wilkinsburg, Pa.

6.—Ernest H. Pearson, Electric Machinery Co., Minneapolis, Minn.

7.—Basil B. Pilcher, 691 East 230th Street, New York, N. Y.

8.—Martin Tracy, Tunnel Camp, Britannia Mines, Howe Sound, B. C., Canada.

9.—Harry Wilson, c/o J. G. White Engg. Corp., Marcus Hook, Pa.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (APRIL 1-30, 1921.)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or text of the book.

All the books listed may be consulted in the Engineering Societies Library.

ALUMINUM.

By George Mortimer. Lond. and N. Y., Sir Isaac Pitman Sons, Ltd. (Pitman's common commodities and industries.) 152 pp., illus., tables, 7 x 5 in., cloth $1.00.

This little book gives a clear description, suited to the needs of lay readers and business men, of the processes by which aluminum is made and of its uses in industry, particularly in automobile and aircraft construction, the chemical industry, electro and electrical engineering.

CHILTON TRACTOR INDEX. Vol. 4, No. 1, January 1921.

Phila., Chilton Co. 456 pp., illus., tables 10 x 7 in., paper. $2.00.

This semi-annual handbook is a reference book for those interested in tractors and farm power machinery. It includes a directory of manufacturers of tractors, specifications of those on the market, with illustrations of most of them, a directory of manufacturers of farm power machinery, electric plants, motor trucks, etc., and a list of makers of tractor parts and equipment. General articles and tables of data valuable to makers and users are also included.

THE ELECTRIC LAMP IN INDUSTRY.

By G. Arncliffe Percival. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd. (Pitman's coommodities and industries.) 112 pp., illus., 7 x 5 in., cloth. $1.00.

A brief non-technical account of the development of electric lamps, with descriptions of the types in use today and the methods of manufacture. Not intended as a technical treatise, but for those desiring a general knowledge of the subject.

THE ELECTRIFICATION OF RAILWAYS.

By H. F. Trewman. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1920. (Pitman's technical primer series.) 78 pp. diagrams, 7 x 4 in., boards, $1.00.

This little volume is an outcome of the discussion as to the advisability or otherwise of electrifying the railroads of Great Britain, a subject of general interest because of the necessity for relieving railway congestion and utilizing coal in the most economical manner. Without going into technical details covered in the books on electric traction, the author brings forward the commercial aspect of the matter and calls attention to some of the main questions to which attention must be paid. Sufficient electrical information is given to enable these points to be understood by readers who are not electricians.

ELEMENTS DE MECANIQUE A L'USAGE DES INGENIEURS: RESISTANCE DES MATERIAUX.

By Robert d'Adhemar. Paris, Gauthier-Villars et Cie, 1921. 185 pp., diagrams, 9 x 6 in., paper.

In writing this book the author has attempted an introduction to the theory of the resistance of materials, in which the hypotheses that have been adopted to simplify the subject in practise are set forth as briefly and simply as is possible.

FIRE TESTS OF BUILDING COLUMNS.

By Associated Factory Mutual Fire Insurance Companies, the National Board of Fire Underwriters, and the Bureau of Standards, jointly conducted at Underwriter's Laboratories in Chicago, 1917-19. 388 pp., illus., charts, tables, 9 x 6 in., cloth. $2.50.

This pamphlet presents the results of an investigation undertaken to ascertain the ultimate resistance against fire of protected and unprotected columns as used in the interior of buildings, and their resistance against impact and sudden cooling from hose streams when highly heated. The results of 91 fire and 15 fire and water tests are given, including tests of representative types of steel, cast iron, concrete-filled pipe and timber columns, protected and unprotected, and reinforced concrete columns. It is stated to be the most complete investigation ever made.

HERBERT HOOVER; THE MAN AND HIS WORK.

By Vernon Kellogg. N. Y. and Lond., D. Appleton & Co. 1920. 375 pp., port., 8 x 5 in., cloth. $2.00.

Dr. Kellogg's book is the attempt of an observer, associate and friend, to tell, simply and straightforwardly, the personal story of the man and his work up to the present. His boyhood, education, work in Australia, China and London are recounted briefly, and much space is given to his work for the relief of Belgium, as American food administrator and as American relief administrator. As appendixes are given four important addresses by Mr. Hoover.

HIGH-TENSION SWITCHGEAR.

By Henry E. Poole. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitman's Technical Primer Series.) 118 pp., illus., 7 x 4 in., boards. $1.00.

The book gives a brief, general account of the subject. The more important points in the design are considered, but highly technical details are omitted, the object being to present the fundamental principles in a practical manner, so that the volume will fill the need for a handy survey of the subject for those who have not time for elaborate treatises.

HUMAN ENGINEERING; A Study of the Management of Human Forces in Industry.

By Eugene Wera. N. Y. and Lond., A. Appleton & Co., 1921. 378 pp., 8 x 5 in., cloth. $3.50.

This volume is a contribution to the discussion of the relationship of labor, capital and society in the industrial development of the world. Neither the old nor the modern school of management has succeeded in removing labor unrest, owing, in the author's opinion, to the ignoring of labor as a social group and disregard of the social purpose of industry. To present the principle of stimulating labor as a whole toward production at large for social purposes is the object of the present work.

The author studies the evolution of the ideas governing industrial relations, interprets the essentials of present issues, presents certain democratic tendencies and develops a typical organization for class cooperation. Other sections analyze the different psychological associations of men involved in industry, discuss the principles of human engineering and outline their application.

THE INTERPRETATION OF RADIUM AND THE STRUCTURE OF THE ATOM.

By Frederick Soddy. Fourth edition, revised and enlarged N. Y., G. P. Putnam's Sons, 1920. 260 pp., plates, illus., 8 x 6 in., cloth. $3.75.

This book is intended as a presentation of the subject in non-technical language, which will bring the ideas involved and their bearing upon current thought within the reach of the lay reader. The present edition has been rewritten to correspond with present knowledge, and a second part has been added in which the later developments, particularly those that bear upon the problem of the constitution of the atom, are set forth in briefer and less elementary form.

JOHN DALTON.

By L. J. Neville-Polley. Lond., Society for Promoting Christian Knowledge; N. Y., The Macmillan Co., 1920. (Pioneers of progress.) 63 pp., port., 7 x 5 in., cloth. $.80.

This brief biography gives the essential facts concerning Dalton's life, but is chiefly devoted to his scientific labors and their influence on chemistry. These are described carefully with as much detail as is usually wanted.

MAINTENANCE OF WAY CYCLOPEDIA.

Compiled and edited by E. T. Howson, E. R. Lewis, K. E. Kellenberg, assisted by Homer Hughes. N. Y., Simons-Boardman Publishing Co., 1921. 860 pp., plates, illus., diagrams, 12 x 9 in., cloth. $15.00.

The aim of the editors of this volume has been to present, in the simplest terms and the most convenient grouping, information covering a wide variety of subjects, of interest to railroad employees, division officers in charge of maintenance, operating officers having supervision over maintenance, purchasing agents and manufacturers. To accomplish this they have selected that which is representative of the best in this field, set forth the standards approved by technical societies and described devices of proved value.

The text is divided into sections covering Track, Bridges, Buildings, Water Service, Signals, Wood Preservation, and General Subjects. The arrangements of each section is alphabetical and the treatment deals with classes of appliances rather than with individual devices. A catalog section gives detailed information on specific contrivances. The volume contains over 2500 illustrations.

MARINE AND STATIONARY ENGINES.

By A. H. Goldingham. Second edition, revised and enlarged. N. Y., Spon & Chamberlain; Lond., E. & F. N. Spon. 1921. 206+27 pp., illus., plates, tables, 8 x 5 in., cloth. $3.15.

This treatise is offered to designers and operators in need of concise, practical information on the various types and designs of Diesel engines. The book opens with a brief account of the theory of the engine. This is followed by a description of the details of construction, and discussions of indicator diagrams, of the advantages and disadvantages of Diesel engines, and of their operation and maintenance. These general topics are followed by descriptions and drawings of many types of engines, illustrated by drawings.

THE MATHEMATICAL THEORY OF ELECTRICITY AND MAGNETISM.

By J. H. Jeans. Fourth edition. Cambridge, University Press. 1920. 627 pp., 10 x 7 in., cloth. $8.00. (Gift of the Macmillan Co., N. Y.)

Contents:—Electrostatics and current electricity.—Magnetism.—Electromagnetism.—Relativity.

There is a certain well-defined range in electromagnetic theory, the author states, which every student of physics may be expected to have covered with more or less thoroughness before proceeding to the study of special branches or developments of the subject. The present book is intended to give the mathematical theory of this range of electromagnetism, together with the mathematical analysis required in its treatment. It is written for the student and for the physicist of limited mathematical attainments.

The main changes in the fourth edition consist in a rearrangement of the later chapters and the addition of a new chapter on the theory of relativity. This attempts to present the broad outlines of the theory in the simplest possible way, suitable for students who approach the subject for the first time, equipped with such knowledge of general electrical theory as can be gained from the rest of the book.

MUNICIPAL ACCOMPLISHMENT IN CITY PLANNING.

Edited by Theodora Kimball. Bost., National Conference on City Planning, 1920. 79 pp. 9 x 6 in., paper.

This pamphlet summarizes the answers to a questionary sent to about 125 American cities that have been interested in city planning. It forms a convenient record of what has been accomplished in this direction during recent years, and lists the specific reports that have been made for the different cities.

NOTES ON IRRIGATION, ROADS AND BUILDINGS AND ON THE WATER SUPPLY OF TOWNS.

By William Lumisden Strange. N. Y., E. P. Dutton & Co., 1921. 849 pp., plates, illus., 9 x 6 in., cloth. $18.00.

In this volume an engineer with thirty years' experience on public works, chiefly in the Indian Public Works Department, presents the results of his professional career for the benefit of younger members of the profession. The book does not deal with matters of design, formulas and similar material available in the usual treatises, but discusses general principles and constructive details.

Much the largest section of the book is devoted to irrigation, which is discussed in considerable detail. The other subjects, town water supplies, roads and buildings are treated briefly. The book refers especially to Eastern conditions, and is intended to aid engineers there, who are usually general practitioners, called upon to carry out many kinds of work.

RADIOTELEGRAPHISCHES PRAKTIKUM

By H. Rein. Dritte auflage, von K. Wirtz. Berlin, Julius Springer, 1921. 557 pp., illus., diagrams, 9 x 6 in., cloth. 120 M.

The needs of the engineer in charge of radiotelegraph and radiotelephone stations are considered in this volume on the technique of plant operation. The various machines and apparatus are described, and their erection, methods of operation and maintenance explained. Directions are given for the necessary measurements, and the derivation of the more important equations is given. The work has been considerably expanded in scope since the publication of the second edition in 1910.

THE TESTING OF MOTIVE-POWER ENGINES

By R. Royds. Second edition. Lond. and N. Y., Longmans, Green and Co., 1920. 392 pp., diagrams, tables, 9 x 6 in., cloth. $7.50.

This book is intended for students with an elementary knowledge of motive-power engineering, who desire information on the practical testing of motive-power engines. Special attention is given to the variable conditions under which a plant may operate and the necessity for systematic arrangements where a series of trials is contemplated.

This edition has been revised and modified to meet modern developments.

THERMODYNAMICS AND CHEMISTRY.

By F. H. Macdougall, N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 391 pp., tables, 9 x 6 in., cloth. $5.50.

This book is intended for the advanced student in chemistry, for whom the author has endeavored to write a book that, in addition to being accurate, logical and sufficiently rigorous, will furnish him with numerous examples of the application of principles of the science.

DIE WARMEVERLUSTE DURCH EBENE WANDE UNTER BESONDERER BERUCKSICHTIGUNG DES BAUWESENS.

By Karl Hencky. Munchen und Berlin, R. Oldenbourg, 1921. 124 pp., illus., tables, 10 x 7 in., paper. 26 M.

This work is based on extensive experiments on the heat conductivity of walls of the usual types and of the customary building materials, carried out at the Munich Technical High School. From the results of these and general laws of the conduction of heat, the author has formulated equations to be used in designing heating installation. The book is intended for architects and for engineers engaged in the design of heating plants as a practical aid in calculating the size of installation.

THE WELDING ENCYCLOPEDIA.

Compiled and edited by L. B. Mackenzie and H. S. Card. Welding Engineer Publishing Co., 1921. 224 pp., illus., 9 x 6 in., cloth. $5.00.

This book is a collection of information on oxyacetylene electric and thermite welding, arranged in concise alphabetical form for ready reference. The material has been largely selected from the files of the "Welding Engineer," and is practical rather than theoretical in character.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—April 26, 1921. Paper: "Automatic Industrial Control." Author: Mr. S. H. Oberschmidt, Sales Engineer, Cutler-Hammer Co. A series of slides illustrating the talk were shown. Attendance 26.

Atlanta.—April 28, 1921. Elec. & Gas Bldg. Business meeting; adoption of Constitution and By-laws. Attendance 18.

Baltimore.—March 18, 1921, Johns Hopkins University. Subject: "Engineering in Connection with Street Railway Problems." Speaker: Mr. Charles De Mott Emmons, President, United Railways & Electric Co., Baltimore. Attendance 110.

April 15, 1921. Johns Hopkins University. Subject: "The Problem of the Electric Motor Car." Speaker: Dr. Charles P. Steinmetz. Attendance 500.

Boston.—May 3, 1921. Engineer's Club, Boston. Subject: "Electric Propulsion of Ships." Speaker: Mr. B. P. Coulson, Jr., General Electric Company, Schenectady. Attendance 85.

Chicago.—March 28, Western Society of Engineers Rooms. The moving picture "Queen of the Waves" was shown, followed by presentation of a paper on "Electric Propulsion for the Merchant Marine" by Mr. Wilfred Sykes, of the Steel & Tube Company of America. Attendance 128.

April 25, 1921. Western Society of Engineers Rooms. Joint meeting of the Chicago Sections of the A. I. E. E., A. I. M. & M. E., Association of Iron and Steel Electrical Engineers and the Electrical Section of the Western Society of Engineers. Papers "Demand Factor of Coal Mining Loads" by Mr. Carl Lee, Peabody Coal Company, and "Power Distribution Systems for Coal Mines" by Mr. W. C. Adams, Allen & Garcia Company. The papers were illustrated with lantern slides, and a film prepared by the U. S. Bureau of Mines and the Peabody Coal Company entitled "Modern Coal Mining Methods" was shown. Attendance 210.

Cincinnati.—April 14, 1921, Assembly Hall, Union Gas & Electric Company. Professor A. M. Wilson, of the University of Cincinnati, explained the operation of and demonstrated the Oscillograph. Col. T. H. Schoepf, Vice-President of the Cincinnati Traction Company, gave an interesting talk on economic operation of the Cincinnati street cars, and showed by the installing of the kilowatt-hour meters how the motormen have materially reduced kilowatt consumption per car mile. Attendance 53.

Cleveland.—April 19, 1921. Cleveland Engineering Society Club Rooms. Mr. R. F. Strickland, of the Nela Park Laboratories, arranged a "Wireless Concert" for the evening. Difficulty was encountered with the apparatus, due to both the receiving and sending apparatus being in high steel buildings. Attendance 248.

Connecticut.—April 22, 1921, Lawn Club, New Haven, Conn. Organization meeting. Adoption of By-laws; election of officers as follows: Chairman, Professor Charles F. Scott; Secretary-Treasurer, Mr. A. E. Knowlton; Executive Committee, Messrs. Samuel Ferguson, W. H. Bristol, W. C. Bryant, E. H. Everit and G. B. Leland. The Speaker of the evening was Dr. William McClellan of Philadelphia, who took as his topic the larger opportunities and obligations of the engineer and made an especial plea that the Section devote its thought to these broader aspects as well as to the details of engineering manufacture or operation. He expressed the wish that the Institute and the Section might indulge in more frank and open discussion of the baffling problems of the engineer. Reference was made to the aims and accomplishments of the recently formed Federated American Engineering Societies and to the fact that most of its work to date had been of the nature of unselfish public service rather than direct efforts to promote the advancement of the engineering profession. In concluding, Dr. McClellan urged that the fluid state of the world's business and political situation demanded that the citizen and engineer take counsel of courage and not of fear. Attendance 43.

Denver.—April 16, 1921. Kenmark Hotel. Subjects: "A Post Graduate Degree in Electric Traction, by a Steam Railroad Executive" by Mr. Ernest Stenger, of the Denver Tramway Company; "The Necessary Improvements in the Denver Water Systems" by W. F. R. Mills, Manager of the Water Commission of the Denver Water System. Attendance 30.

Detroit-Ann Arbor.—March 17, 1921. Subject: "Induction Motors." Speaker: Mr. Lane, Chief Engineer, Westinghouse Company. Attendance 250.

April 8, 1921. Subject: "Storage Batteries for Motor Power Service." Speaker: Mr. H. M. Beck.

Erie.—May 10, 1921, Academy High School Election of officers, for ensuing year as follows: Chairman, Mr. C. H. Schum; Secretary, Mr. P. B. Mansfield; Executive Committee, Messrs. H. Lamp, James Burke and H. Hansen. Subject: "Energy in its Relation to Modern Theory." Speaker: Dr. Charles P. Steinmetz. Dr. Steinmetz gave a popular exposition of the relativity theory, making use of several simple analogies, and avoiding all use of mathematics. Attendance 1385.

Fort Wayne.—April 21, 1921. G. E. Club Rooms. Subject: "Clocks and Watches, the History, Principles and Devices of Time-Keeping." Speaker: Mr. Chester I. Hall. After the talk the audience witnessed several interesting motion pictures including the manufacture of lead storage cells and the early discoveries relating to electricity. Light refreshments and smokes were provided by the Entertainment Committee. Attendance 40.

Indianapolis-Lafayette.—March 25, 1921, Chamber of Commerce, Ind. Subject: "Artificial Precious Stones." Speaker: Professor Frank B. Wade, Shortridge High School. Attendance 55.

April 29, 1921, Chamber of Commerce Building. Subjects: "The Effects of Low Power Factor Upon the Distribution of Electrical Energy and their Relation to Rate Schedules" by Professor C. Francis Harding, Purdue University; "The Determination of Power Factors in Polyphase Circuits" by Professor D. D. Ewing, Purdue University. Attendance 77.

Ithaca.—March 25, 1921, Franklin Hall, Cornell University. Papers: Abstracts were presented by various members of the School of Electrical Engineering of Cornell University as follows: "The Report on the Atlantic Super-Power Project," by Messrs. B. K. Shaner and H. A. Metzger; Lamme's "Story of the Induction Motor," Mr. R. C. Burt; "Automatic Stations and Substations," by G. C. Firket and C. Y. Yeh; "Flutter in Telephone Transmission," S. J. Cammataro. Attendance 23.

Kansas City.—April 29, 1921, University Club. Paper: ""Steam Turbines and Turbo-Generators." Author Mr. C. C. Douglas, of the General Electric Compay. The paper was illustrated by slides. Two reels of motion pictures entitled "Queen of the Waves" were also shown. Attendance 34.

Lehigh Valley.—May 5, 1921. Organization meeting. Adoption of By-laws; election of officers as follows: Chairman, Mr. L. C. Brooks; Secretary, Mr. H. G. Harvey. The meeting was held jointly with the Easton Educational Electrical Association. A moving picture furnished by the Westinghouse Elec. & Mfg. Co., entitled "A Romance of Rails and Power" was shown, followed by a most interesting and instructive talk by Dr. William McClellan on "The Broader Outlook of Engineering." The subject was dealt with in a broad manner

and appealed strongly for a more active interest in civic and political affairs on the part of engineers in general. Attendance 113.

Los Angeles.—April 22, 1921, Edison Hall. Subject: "Insulation of Extra High-Voltage Transmission Lines." Speaker: Professor Harris J. Ryan. (Illustrated by lantern slides). Mr. Harold Michener reviewed the history of the transmission insulator in Southern California leading up to the report of Mr. R. J. C. Wood on 220 kv. Insulator Studies. Mr. Wood gave a graphic description illustrated by numerous lantern slides of the studies made at Stanford University and in the Edison Laboratory on suspension insulator strings for 220 kv. lines. Attendance 140.

Milwaukee.—April 8, 1921. Local section Membership Committee gave a dinner at the Blatz Hotel in welcome to the newly elected members of the Section and applicants. Mr. A. W. Berresford, President of the A. I. E. E., was present and related in an interesting way incidents of his recent trip to England. He also covered briefly, for the benefit of the new members, the various phases of the activities of the A. I. E. E. and The Federated American Engineering Societies. Attendance 126.

April 20, 1921, Milwaukee Athletic Club. Subject: "The Social and Economic Status of the Engineering Profession." Speaker: Professor John C. Parker, University of Michigan. Professor Parker suggested that the standard of the engineering profession could be raised by increasing the college course to six years, and to include in the curriculum subjects which would prepare the engineer to take a more active part in the affairs of the nation. Attendance 200.

Minnesota.—March 28, 1921, Y. M. C. A. Subject: "Application of Electrical Energy to Industrial Processes." Speaker: Mr. V. A. Hain, General Electric Company, Chicago. The speaker enumerated the various uses to which electric ovens and furnaces are now being used, and pointed out the wide range of application to which this apparatus could be put today. He further gave the figures indicating the rapid growth and relative amounts of electrical energy used today in this class of industrial application. Attendance 22.

Philadelphia.—May 9, 1921, Drexel Institute. Subject: "Advantages of the Institute to Engineering Students". Speaker: Mr. H. P. Liversidge, The Philadelphia Electric Company. Films on various phases of the Electrical Industry were shown as follows: "Spiragraph," "Conquest of the Forest," "Revelations by X-Rays," "The Electrical Giant," "Forging Lines of Fellowship," "Making Telephones in Tokio." Attendance 204.

Pittsfield.—April 14, 1921, Park Club. Subject: "The Magnitude of the Stars." Speaker: Dr. Harlan T. Stetson, Professor of Astronomy, Harvard University, Cambridge, Mass. Attendance 125.

Portland.—March 22, 1921, University Club. Subject: "The Atlantic-Pacific Highways and Electrical Exposition." Speaker: Mr. John E. Gratke. A one-reel film entitled "The Electrical Giant" was also shown. Mr. Charles Austin, Radio Expert, gave a practical demonstration of wireless telephony and telegraphy which proved very interesting and instructive. Attendance 103.

April 22, 1921, Multnomah Hotel. In place of the regular meeting the Section joined in the Merchandising Conference" given by the General Electric and the Pacific States Electric Companies. As an added attraction, Mr. Robert Sibley made an address on "What Electrical Development means to Portland and the Columbia Basin." Attendance 50.

Providence.—May 3, 1921, Rooms of the Providence Engineering Society. Joint meeting with the Power Section of the Providence Engineering Society. Subject: "Bituminous Coal Stoker Practise." Speaker: Mr. F. C. Vandervort, Jr., of the Westinghouse Elec. & Mfg. Co. Attendance 40.

Rochester.—April 22, 1921. Mr. K. A. Hawley of the Locke Insulator Company, presented a discussion of the insulation of superpower lines. Mr. Hawley described the difficulties to be overcome in insulating the 220,000 volt lines soon to be put in service on the Pacific Coast. He described the results obtained in the laboratory by using graded strings of insulators and static shields to obtain better voltage distribution across long strings of suspension units. Attendance 48.

San Francisco.—March 24, 1921, Engineers' Club. Joint meeting with the American Society of Mechanical Engineers. Subject: "Efficiencies in Steam-Driven Power Plants." Speakers: Messrs. Robert Sibley and E. H. Delaney. Attendance 60.

Schenectady.—April 15, 1921, Edison Club Hall. Subject: "Illuminating Engineering." Speaker: Mr. W. D'A. Ryan, Director, Illuminating Engineering Laboratory of the General Electric Company. Colored slides were shown covering four main topics, historic lighting, from the early ages to the present, the Panama Pacific Exposition, modern street lighting and spectacular illumination. Attendance 210.

April 22, 1921, Edison Club Hall. Subject: "Engineering Organization." Speaker: Mr. A. W. Berresford, President of the A. I. E. E. Following an interesting discussion two motion picture films were shown, entitled "A Woolen Yarn" and "Our Daily Bread." Attendance 120.

May 6, 1921, Edison Club Hall. Subject: "The Origin and Energy of the Lightning Flash." Speaker: Dr. Charles P. Steinmetz. Dr. Steinmetz discussed the various phases of lightning explaining the theory thoroughly from beginning to end. All points were illustrated by pictures and explained by mathematical examples. Attendance 435.

Seattle.—April 19, 1921, Arctic Club Assembly. Subject: "The Introduction of the Automatic Telephone in Seattle." Speaker: Mr. D. J. Lundy. The speaker explained the operation of the new equipment and the procedure in connection with calls transferred from the automatic system to the manual. Diagrams and models were used in the explanation of the new system. Attendance 90.

Spokane.—April 15, 1921, Spokane Hotel. Dinner meeting. Subject: "Some Features of Early Electrical Developments in Spokane." Speaker: Mr. John B. Fisken. Attendance 38.

Syracuse.—March 10, 1921, Technology Club. Subject: "Recent Developments in Generators and Power Station Design." Speaker: Mr. F. D. Newbury, of the Westinghouse Elec. & Mfg. Co. Attendance 40.

April 15, 1921, Engineering College, Syracuse University. Subject: "The Oscillograph and Harmonic Analyzer." Speaker: Professor Charles W. Henderson. The address was accompanied by lantern slides showing oscillograms resulting from connecting various apparatus to circuits. Mr. Henderson also had a considerable amount of apparatus displayed for the inspection of those present. Attendance 47.

Toronto.—April 22, 1921, Toronto University. Subject: "The Cost of Power as influenced by the Present Economic Trend." Speaker: Mr. Paul M. Lincoln. The important points emphasized by the speaker were: In establishing energy charges, the quantity demand is fully as important as the integrated energy and often more so; demand should be measured, not estimated; power factor should be recognized in demand determination. Attendance 100.

Urbana.—April 15, 1921. Subject: "The Manufacture of Insulated Wires and Cables" (illustrated). Speaker: Mr. W. I. Middleton, of the Simplex Wire & Cable Co. Attendance 87.

Utah.—April 22, 1921, Commercial Club. Subjects: "The Manufacture of Leather Belting" by R. S. Nelson, of Charles A Schieren Company; "Electrical Developments in the West" by Mr. George E. Armstrong, Pacific Coast Editor, *Electrical World*. Attendance 35.

Washington.—April 12, 1921, Cosmos Club. Subject: "Storage Batteries, Their Characteristics and Applications"

(illustrated). Speaker: Mr. J. Lester Woodbridge, of the Electric Storage Battery Co. Attendance 181.

May 10, 1921, Cosmos Club Hall. Election of officers, for ensuing year, as follows: Chairman, Mr. A. R. Cheyney; Secretary, Mr. W. A. E. Doying; Executive Committee, Messrs. G. H. Ferry, Milton M. Flanders, Edward Kirschner, C. B. Mirick and R. P. Parrott. Two moving pictures entitled "Revelation" and "The Conquest of the Forest" were shown. Attendance 90.

PAST BRANCH MEETING

Alabama Polytechnic Institute.—May 5, 1921. Election of officers as follows: Chairman, V. C. McIlvaine; Secretary and Treasurer, J. M. Dickinson. Mr. V. C. McIlvaine delivered a talk on "Radio Operation and Engineering." Attendance 25.

University of Arkansas.—April 12, 1921. Subjects: "Should the Arkansas Corporation Commission Have Been Abolished" by Mr. S. Hollabaugh; "Some Facts about Centrifugal Pumps" by Mr. J. B. Rogerson. Attendance 11.

April 19, 1921. Subjects: "Automatic Control of Railway Substations" by Mr. L. C. Starbird; "Review of Industries in Europe" by Mr. Max Ware. Attendance 7.

Bucknell University.—April 20, 1921. Professor Hall gave Tesla Coil demonstration, also demonstrations with Geissler Tubes. Attendance 95.

Case School of Applied Science.—April 12, 1921. Subject: "The Industrial Application of Electrical Heating Appliances" (illustrated with slides). Speaker: Mr. R. A. Kaighen, of the Cleveland Illuminating Company. Attendance 38.

California Institute of Technology.—April 7, 1921. Mr. A. B. Allen of the Pasadena Municipal Light Plant gave practical demonstrations for action in electric shock or drowning accidents. Mr. O. C. Bulkley, a junior in electrical engineering gave a complete account of the changes in the National Electrical Code, and the inspection requirements for Pasadena installations. Attendance 17.

University of Cincinnati.—April 19,1921. Subject: "The Piping of Live Steam for Heating in Dayton, Ohio." Speaker: Mr. H. E. Deadorff, E. E. '22. Attendance 71.

April 26, 1921. Subject: "Maintenance of Electric Machinery." Speaker: Mr. M. S. Schneider, E. E. '22. Attendance 65.

May 3, 1921. Subject: "Electric Time Recording Devices." Speaker: Mr. Harlan Danner, E. E. '24. Attendance 40.

May 7, 1921. Annual stag. Professor A. M. Watson, toastmaster. Adresses by the following: Professor C. B. Hoffmann and Messrs. R. S. Redman, G. C. Browne, Andre Pingon, C. Doran, Francis Healey, and Dean Herman Schneider. Attendance 90.

May 10, 1921. Subject: "The 220-Kv. California Problem." Speaker: Mr. R. S. Redman. Attendance 57.

Clemson Agricultural College.—May 2, 1921. Subject: "From Falls to Factory." Speakers: Messrs. Abernathey and Spearmar. "Current Events by Mr. J. R. Rosa. Attendance 25.

University of Colorado.—April 21, 1921. Subject: "Construction and Operation of Power Transmission Lines" (illustrated). Speaker: Mr. Norman Reid, of the Colorado Power Company. Attendance 42.

Georgia School of Technology.—April 12, 1921. Subject: "The Relation of the Employer to the Technical Graduate." Speaker: Mr. W. R. Collier, Sales Engineer, Georgia Railway & Power Company. Attendance 26.

May 3, 1921. Joint meeting of local Branches of A. I. E. E. and A. S. M. E. The moving picture entitled "Queen of the Waves" was shown. Attendance 135.

Iowa State College.—April 20, 1921. The following films were shown: "Jupiter's Thunderbolts," "General Electric Company, Schenectady Works," "Big Deeds," "Romance of the Hardwoods" Attendance 78.

University of Iowa.—April 11, 1921. Subjects: "Selenium" by Mr. D. C. Shuttice, and "Mississippi Power Company" by Mr. F. Stohr. Attendance 33.

April 18, 1921. Subjects: "Seven Hundred Miles of Wire" by Mr. R. J. Tompkins, and "The Ohio" by Mr. E. Wilsey. Attendance 28.

April 23, 1921. Subjects: "Valuation" by Mr. R. L. Schacht, and "Future Wireless Telephony" by Mr. R. Wright. Attendance 26.

Kansas State College.—April 11, 1921. Election of officers as follows: Chairman, W. J. Bucklee; Vice-Chairman, L. E. Rossel; Corresponding Secretary Harold S. Nay; Recording Secretary, J. E. Beyer; Treasurer, G. L. Garloch; Marshall, M. C. Watkins. Attendance 38.

University of Kansas.—April 27, 1921. Election of officers as follows: Chairman, Erle S. Miner; Vice-Chairman, Henry Albach; Secretary-Treasurer, Clarence Harris. Subject: "Telephone Engineering." Speaker; Mr. C. J. Larsen, of the Kansas City Telephone Company. Attendance 30.

Lehigh University.—April 14, 1921. Papers: "Electric Furnaces" by Mr. E. F. DeTurk, E. E. '22, and "Departures from the Beaten Track" by Dr. Carl Hering. Attendance 73.

Michigan Agricultural College.—May 5, 1921. Chairman Fleming and Professor Sawyer talked on the advantages and possibilities of the A. I. E. E.; Mr. E. V. Sayles, a senior, explained some of the uses of the Terrill Regulator which he with several other seniors have obtained for the use of the department and are studying. Professor Cory gave a short talk on the opportunities of the electrical engineer. Refreshments were served. Attendance 70.

School of Engineering of Milwaukee.—April 22, 1921. Mr. C. E. Pettengill gave an interesting talk and demonstration of the "Headlight Laws" covering the following points: Demonstration of the various makes and types of lenses, discussion of the various state laws pertaining to automobile headlights, engineering problems which arise in connection with designing of the lenses and drawing up of the various state laws, actual demonstration of a pair of lenses on the street showing proper adjustment, etc. Attendance 58.

University of Missouri.—April 4, 1921. Election of officers as follows: Chairman, Professor A. C. Lanier; Vice-Chairman, R. P. Miller; Secretary, F. H. Miller; Assistant Secretary, B. C. Knerr; Corresponding Secretary, J. S. Palmer; Treasurer, E. J. McNeeley. Subject: "Use of Carrier Current in Telephony." Speaker: Mr. W. L. Blenden. The following moving pictures were also shown: "Romance of the Rails" and "King of the Rails." Attendance 35.

North Carolina State College.—March 15, 1921. Business meeting. Attendance 29.

March 23, 1921. Committees appointed for the electrical show. Attendance 25.

April 6, 1921. Time devoted to work on the exhibits for the electrical show. Attendance 25.

April 22, 23 and 25, 1921. Annual Electrical Show.

April 27, 1921. Election of officers as follows: Chairman, E. E. Inscoe; Vice-Chairman, H. S. Hill; Secretary-Treasurer, O. L. Bradshaw. Attendance 24.

University of North Carolina.—May 6, 1921. Subject: "Lighting from the Engineer's Viewpoint." Speaker: Professor P. H. Daggett. Attendance 35.

University of Notre Dame.—April 11, 1921. Subject: "Phenomena of the Induction Coil." Speaker: Mr. Ruzek. Attendance 18.

Ohio Northern University.—April 21, 1921. Subjects: "Resources of Niagara" by Mr. W. Janke, and "Romance of Invention" by Mr. D. Wolf. Attendance 14.

Ohio State University.—April 15, 1921. Subject: "Automobile Ignition." Speaker: Mr. J. H. Hunt, of the General Motors Research Corporation, Dayton, Ohio. Attendance 100.

Oregon State Agricultural College.—April 20, 1921. Discussion of the following papers "Development of Standardization" and "National and International Standardization." Attendance 20.

University of Pittsburgh.—April 12, 1921. The following papers were discussed: "The Amateur Wireless Station" by W. H. Raring, and "Electric Bonding & Coal Mining" by J. A. Connell. Attendance 30.

April 26, 1921. Subjects: "The Outlook of the Engineer for the Future" by C. W. Merritt; "Operation of the Power Plant at Jones and Laughlin Steel Mills" by R. P. Marshall; "Varying Currents" by W. H. Robinson. Attendance 29.

May 3, 1921. Subjects: "Wiring and Lighting Current Pertaining to Motion Picture Theatres" by W. L. Shutts; "Electroplating Industry in the U. S." by L. L. Hughes; "Loud Speaking Telephone Receivers" by J. O. Kleba. Attendance 31.

Purdue University.—February 22, 1921. The moving picture entitled "The Benefactor" was shown. Attendance 112.

March 22, 1921. Subject: "Business Letter Writing." Speaker: Dean A. A. Potter. The moving picture entitled "Big Deeds" was also shown. Attendance 69.

April 7, 1921. Subject: "Manufacture of Wire and Cable." Speaker: Mr. W. I. Middleton, of the Simplex Wire & Cable Co. Attendance 29.

April 26, 1921. Subject: "Electric Power Plants of Michigan." Speaker: Mr. H. J. Burton of the Consumers Power Company of Michigan. The film entitled "Revelations" was also shown. Attendance 87.

Rose Polytechnic Institute.—April 21, 1921. Subject: "Commercial Illuminating," illustrated with motion pictures. Speaker: Mr. J. T. McNarrow. Attendance 138.

Syracuse University.—April 22, 1921. Subject: "Electrification of Railroads." Speaker: Mr. George V. Round. Attendance 13.

University of Texas.—April 19, 1921. X-Ray Demonstrations by Dr. Dalton Richardson, of the Austin X-Ray Laboratory. Attendance 20.

Virginia Military Institute.—April 23, 1921. Subject: "Modern Refrigerating Plant." Speaker: Mr. Howard V. Shipley. Attendance 42.

Virginia Polytechnic Institute.—April 11, 1921. Subject: "The Theory of Sending and Receiving Messages by Wireless," illustrated by diagrams, and practical demonstration. Speaker: Mr. G. H. Poehlman. Attendance 18.

University of Virginia.—March 17, 1921. The following moving pictures were shown: "Queen of the Waves," "Land of Cotton," "The Potters Wheel," "Panama Canal." Attendance 46.

State College of Washington.—April 9, 1921. Joint meeting of local Branches of A. I. E. E. and A. S. M. E. Subject: "What a Student Should Get Out of his College Education." Speaker: Mr. H. L. Melvin. Attendance 80.

University of Washington.—April 14, 1921. Subject: "Recent Radio Developments." Speaker: Mr. J. Tolmie. Attendance 12.

West Virginia University.—April 25, 1921. Subjects: "The Colfax Power Plant" by C. M. Hill; "Electric Dredging on the Yukon" by H. Chandler; "Some Recent Developments in the Electrical Industry" by R. B. Walker. Attendance 16.

Yale University.—May 10, 1921. Subject: "The Birth and Babyhood of the Telephone" by Dr. Thomas A. Watson. A discussion of Dr. Watson's paper by Mr. J. T. Moran of the Southern New England Telephone Company. General short talk on the telephone by Messrs. Scott and Underhill. Attendance 205.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

MEN AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y., the employment clearing house of the Societies constituting the Federated American Engineering Societies.

Notices for the JOURNAL are not acknowledged by personal letter, but they will usually appear in the next issue that goes to press.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to EMPLOYMENT SERVICE, as above.

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

OPPORTUNITIES

LINEMEN AND LINE FOREMAN, first class. Location southeast. X-554.

ASSISTANT RESIDENT ENGINEER to supervise operation and maintenance of boilers, turbines and mechanical equipment of plant, reporting direct to Resident Engineer, who is in charge of entire installation. Must know how to direct proper burning of heavy Mexican crude oil in boiler plant. Must know how to make performance test on burners, boilers and turbines. Must know the keeping of complete and accurate plant operation data. Must be able to supervise the maintenance of plant equipment. Must have had at least five years' experience as operating engineer or superintendent in charge of steam and of large modern steam turbine plant, either commercial or industrial. Must be a graduate in mechanical or electrical engineering from one of the leading technical schools, such as M. I. T., Yale, Stevens, Pratt, Troy Polytechnic, etc. Spanish desirable but not essential. Age preferably about 35 years. Married or single, either. Both man, wife (if married) must be decent, high type, clean living people. Man must be good executive, good organizer, good handler of men and not a disturbing element. Three year contract. Location Chile. X-555.

INSTRUCTOR in Electrical Engineering in middle west state institution with 700 engineering students. Prefer a man with a little practical experience in addition to college course in line construction, house wiring or armature winding, although Instructor will not be expected to do any of this kind of work. Position for nine months, September 1st to June 1st. Location Middle West. X-556.

INSTRUCTOR who has an electrical engineering education and is qualified to teach general physics. After next year entire time would be devoted to engineering courses. For

the present would be expected to give one elementary course in a-c. and d-c. work with two lectures and one laboratory period each week; one advanced E. E. course of his own selection; one course in steam engineering and the balance of his time would be given to physics. Location South. X-532.

ELECTRICAL ENGINEER who understands small d-c. meter and generator winding; must have good experience with mechanical and executive ability, if not a worker do not apply; good salary to right man. First letter state full facts of past experience. Location South. X-533.

ENGINEER with fractional horse power motor experience. Location Ohio. X-535.

SALES ENGINEER acquainted with the application of electric motors to sell on commission basis d-c. power motors and either d-c. or a-c. grinders and polishers. Territory open—Boston, Pittsburgh, Cleveland, Cincinnati and St. Louis. Would not interfere with handling a non-competitive line selling to the same class of trade. X-542.

MECHANICAL UNIVERSITY GRADUATE for sales work with well established electrical manufacturers. Location Missouri. X-500.

CHIEF METER TESTER. Location Panama. X-507.

SALESMAN for company making electric fixtures. Sales experience essential. Interview 9-10. Commission basis. Location Greater New York City. X-510.

INSTRUCTOR for Electrical Engineering Department. Term beginning September. Send full information in first letter, and give three or more references. Location West. X-467.

ILLUMINATING ENGINEER for work on industrial lighting problems for contracting and electrical engineering firm. Man with wide industrial and some sales experience desired. One who would consider compensation on salary and commission basis preferred. Location Toronto, Canada. X-473.

ELECTRICAL ENGINEER. Prominent technical school has a permanent opening commencing September for a graduate engineer to take charge of electrical laboratory instruction. Experience of several years in electrical industry essential and one or two years' teaching experience desirable but not absolutely necessary. Location New York City. Excellent prospects for advancement. State fully education and experience; also age and religion; specify salary expected. Recent photograph desirable. X-476.

PROFESSOR OF ENGINEERING. Good ability, good appearance and one who is a good mixer. Preliminary work of the students is taken in college so that first year men are seniors or graduates. Second year men are graduates. Since the relations between students and instructors are very intimate it is necessary for cooperative organization work on the part of the instructors. Personality of the instructor is of great importance. Work will commence middle of July or September, preferably the former. After this year it will be from July 1 to May 1. Courses to be carried are Electricity and others according to experience of the man. Hydraulics and Heat and Power will probably be included. Application by letter. Location N. H. X-489.

TELEPHONE ENGINEERS capable of laying out a modern and up-to-date telephone exchange of central energy type in a town of about 15,000 population. Prefer a man with some little experience. Location Missouri. X-492.

SALES ENGINEERS with demonstrated selling ability to sell Elevator Guide Rail lubricator. Experience in building supply or power plant specialty lines desirable. Long residence in the city where they intend to work would be helpful. Men 25-35 would be most suitable. Territory open—Chicago, Philadelphia, Detroit and Cleveland. X-348.

SALESMAN to sell commutator stones in New York City and vicinity on commission basis. X-354.

INSTRUCTORS, two, in Electrical Engineering Department. Location Georgia. X-267.

MECHANICAL ENGINEER; Young man, single, for work in tropics, under direction of competent managing engineer, in enterprise established over thirty years. Prefer man having two or three years student courses in Westinghouse or General Electric. Work embraces simple building operations, road construction, operation steam and electric generating plants, drafting, designing plant changes and improvements and simple survey work. Three year contract. Liberal vacation allowance, free medical attendance, board and quarters. Excellent opportunity advancement if ability demonstrated. Submit full statement training, experience and character references. X-570.

MEN AVAILABLE

GRADUATE in law and electrical engineering; good knowledge of French and Russian; six years experience in U. S. and abroad; test floor, design and layout of switchboard, general engineering in turbine and turbo-generator work; familiar with estimating. Married. Desires position with consulting engineers or manufacturing concern; work along commercial lines considered E-2689.

PLANT AND CONSTRUCTION ENGINEER, age 33; technical graduate. Five years electrical construction, including power house, transmission line and substation. Four years mechanical and general plant construction. Two years steam plant operating and testing. Prefer position as plant engineer manager or assistant manager. Excellent references. Now employed; available on reasonable notice E-2690.

ELECTRICAL ENGINEER, experienced in design and construction of high and low-tension stations, also lighting and industrial layout work, desires to make change. Would consider position with engineering concern doing work of this character. Minimum salary $3000. E-2691.

ELECTRICAL ENGINEER, age 22; single. Graduate in June. Practical experience in contracting and construction. Commissioned in U. S. Engineers' O. R. C. Desires position with chance for advancement. Available July 1st. E-2692.

EXECUTIVE ENGINEER. Ten years electrical operation, construction and management, supervising engineer and industrial appraiser; two years Army, Captain Artillery; college graduate, age 32; married. In addition to technical and practical training, has a broad literary education, can write a clear concise letter, is strong on organization, and can fit in any where. E-2693.

ELECTRICAL ENGINEERING TEACHER desires change. Minimum salary $3500. Broad training and experienced along practical lines. Would consider either teaching or commercial work. Prefer teaching. E-2694.

ELECTRICAL ENGINEER, B. S., degree; age 25; single. Seven months experience with Westinghouse graduate student course. Desires position affording opportunity for advancement. E-2695.

TECHNICAL GRADUATE, age 31, desires position as electrical engineer or assistant with central station company, or as field engineer with consulting or constructing firm. Has had twelve years' broad experience in electric power plant, transmission and distribution design, construction, maintenance and operation. Available on short notice. Any location. E-2696.

ELECTRICAL ENGINEER, age 29; single. Two years G. E. test; two years G. E general engineering department on central stations. Associate A. I. E. E. Desires position with central station or construction company. Location Middle West. Good reference; available at once. E-2697.

GRADUATE ENGINEER, B. S. in E. E. 1920, age 25; married. Will receive degree of M. S in E. E. in June. Instructor in Physics Laboratory for three years. Have had experience in power house operation. Also experience in construction work. Interested in generation and distribution of electric power. E-2698.

MEMBER with twenty years experience covering shop supervision, invention, development and design of motor control apparatus and five years as chief of engineering department desires to make a change. Am seeking an executive position where past experience can be used and with prospect of advancement. Age 40; married. E-2699.

GRADUATE ELECTRICAL ENGINEER, age 30; desires sales or business connection. Considerable experience in sales correspondence. One years' experience in radio engineering. Also experienced in electrical testing. Preferred location; Wisconsin or vicinity of Chicago. At present employed, but available immediately. E-2700.

ELECTRICAL ENGINEER, age 34; with doctor's degree and of wide experience in development and design work, desires position in electrical enginering department of a university or research laboratory. E-2701.

TECHNICAL graduate; six years broad experience; design of industrial and power plants, chemical works, mining, special machines and apparatus. One position for three years as engineer and purchasing agent handling eight plants; each in a separate industry. Available immediately. Make offer. E-2702.

ELECTRICAL ENGINEER, married; fifteen years' experience in electrical and mechanical lines, including consulting and general construction work, design, installation and maintenance of industrial and commercial plant equipment, substations, overhead and underground distribution sys-

tems, etc. Desires position as plant electrical engineer or in consulting field. E-2703.

ELECTRICAL ENGINEER, age 23, graduating from college in June would like to become connected with an electric railway company or else one putting in steam and hydroelectric power plants. Has had some construction experience but would be willing to start from the bottom up with the right concern. E-2704.

ELECTRICAL ENGINEER having nine years' experience in design and operation of electric light power systems desires position with central station company or large engineering firm. Can handle men. Experience includes power station, substations, transmission, and a-c. and d-c. distribution overhead and underground. University graduate; married. E-2705.

ACTING DEAN AND PROFESSOR of electrical engineering in a State University was my last educational position. Attended Westinghouse Teachers' Conference and spent last years renewing practical experience. Member A. I. E. E.; A. A. E.; I. E. S. and S. P. E. E. Age 38; widowed; no family. Marked executive ability. Desires position of responsibility, in medium sized engineering school. E-2706.

MANAGER, SUPERINTENDENT, or executive electrical engineer. Technical graduate. Twenty-two years experience in steam and hydroelectric power plants, electric railways systems, high-tension transmission, low-tension distributing system and industrial layouts. Broad experience with public utility. Lately manager and engineer at hydroelectric power plant. Salary commensurate with position. Available immediately. E-2707.

ELECTRICAL ENGINEER, technical graduate; age 28; unmarried. Twenty months G. E. test, including turbines, motors, generators (a-c. and d-c.) regulators, transformers, panels, and calculation of test data. Experienced in industrial application of power and capable of making complete installations. Also technical correspondent. Available on short notice. References. E-2708.

SHRINKAGE ENGINEER. Industrial or public utility. Twelve years' experience electrical design, construction, inspection, maintenance and analysis work with electric power, street railway and telephone companies and U. S. Gov't. Technical graduate. Taking Alex. Hamilton Inst. Course. Seeking permanent position in New York or New Jersey or temporary anywhere. E-2709.

ELECTRICAL DESIGNER member A. I. E. E. age 35, married; Twelve years' experience in the design of power houses and substations and development of control apparatus. Desires position with concern in middle West with opportunity for advancement. E-2710.

ELECTRICAL ENGINEER with broad experience in power plant construction and operation for mining and handling of coal and ores; especially successful in handling labor. No objection to isolated location. Salary governed by location and opportunities. Served 3 years Major C. of E. U. S. A. E-2711.

CORNELL GRADUATE in electrical engineering, age 22; desires position with engineering, manufacturing or power company with opportunity for experience and advancement. Eight months' experience with Westinghouse. Available on short notice. E-2712.

PROFESSOR of electrical engineering; age 32. Five years experience as associate professor in leading technical colleges; also Westinghouse test course; engineer with large public utilities and consulting work. At present technical assistant to head of department of transmission of large public utility. Member A. I. E. E. and Illuminating Engineers. Text on electric power transmission in preparation. Desires position as head of department or professor in technical school of recognized standing, or as research engineer. Present salary $3600. E-2713.

ELECTRICAL ENGINEER, technical graduate. Five years General Electric Company. Two years on test. Sales experience. Specializes on motors. Electrician sergeant Coast Artillery during war. Wants connection where there is room for advancement. Age 22; Associate A. I. E. E. Available on short notice. E-2714.

CENTRAL STATION AND RAILWAY MANAGER and engineer. Technical graduate. Fifteen years' experience with large central station, railway, and lighting properties. Seeks position in executive or engineering capacity with central station, railway or industrial corporation, or engineering firm. Experience as sales engineer and on electrical construction. E-2715.

ELECTRICAL ENGINEER, age 27; married, three years' experience in testing and designing of electrical apparatus of all kinds, one year as an instructor in a mid-western University desires position with operating or construction company during the summer. Will also consider an instructorship during summer school. Member A. I. E. E., American Physical Society and American Mathematical Society. Best references. E-2716.

GRADUATE ELECTRICAL ENGINEER, age 29, married. At present in transportation department of large street railway company, wishes to make change. Five years experience electric street railway maintenance and operation; nine months sales engineering experience with well-known company manufacturing electric wires and cables. Desires permanent position in sales engineering with company manufacturing electric railway supplies or other electric machinery or devices. Would also consider permanent position in traffic analysis work or similar work allied to electric railway industry. New York City or Middle Atlantic States preferred. References furnished upon application. Available on two weeks notice. Mininum salary $3000. E-2717.

ELECTRICAL MECHANICAL ENGINEER, age 30; married. Member A. I. E. E. Four years' experience, electrification of steam railroads including layout and installation of apparatus and locomotive operation. Two years, Transportation Corps, U. S. Army, Asst. Supt. of Motive Power. One year in charge Experimental Dept. of large rubber tire company. E-2718.

RAILWAY ENGINEER. Extensive and varied experience in maintenance of both a-c. and single-phase equipment. Familiar with heavy traction electric locomotives and with multiple unit cars. Desires to connect with road serving growing territory in a responsible capacity. E-2719.

YOUNG MAN, age 24; married; wishes position where the following experience will prove of value. Three years underground transmission work; two years testing of motors and generators; one and a half years inspection and repair of electric controlling apparatus with some order department work. Graduate N. Y. E. S. and Assoc. Member A. I. E. E. Available immediately. New York City and vicinity preferred. E-2720.

ENERGETIC ELECTRICAL MECHANICAL ENGINEER desires position with public utility or industrial concern. Technical school and hard business education. American, age 38; wife and child. Eighteen years' experience in active management electric light, central steam heating, water works and telephone plants. Understands plant and commercial departments. Can handle public. Salary $5000. E-2721.

YOUNG ELECTRICAL ENGINEER, age 23, single. Technical education. Three years' experience in power plant and transmission work; four years' experience as mechanical and electrical designing draftsman. Desires position as an assisting engineer with a concern with good opportunity for advancement. Best of references. Associate A. I. E. E. Available immediately. E-2722.

GRADUATE ELECTRICAL ENGINEER, age 29. Two years General Electric Test. One and one-half years construction work; two years teaching in large university; one year in army. Would like to work for a large public utility in a place where he can study the management end of the game. Western location preferred. E-2723.

ELECTRICAL ENGINEER, age 32; married. Seven years' experience with large public service company. Five years in charge of construction as district superintendent. Familiar with line and cable construction. Also experience in manufacturing industry. Desire executive position. Salary $5000. E-2724.

ELECTRICAL MECHANICAL SUPERINTENDENT. Twelve years' experience in the design, construction, operation and maintenance of steam and hydroelectric generating stations, substations, low and high-tension transmission and distribution systems, Ex-Army officer (Major), broad experience in the handling of men; labor problems and work requiring executive and organizing ability. Member A. I. E. E. Age 34; available 15 days. E-2725.

TECHNICAL GRADUATE in electrical engineering; B. S. degree; member A. I. E. E.; age 24; single, wishes connection in engineering, manufacturing or light and power company, as construction engineer, affording opportunity for advancement. One years' experience. Location anywhere; available immediately. E-2726.

ELECTRICAL MECHANICAL TESTING ENGINEER, age 31; married; technical graduate. Six years' experience in operating, engineering and testing departments of the largest central station company in the middle West. Two years inspecting material at places of manufacture; two years chief inspector with large motor manufacturer. Associate A. I. E. E. E-2727.

PROFESSOR OF ELECTRICAL ENGINEERING, in one of our large universities for fifteen years desires to return to university

work in electrical engineering; has about finished the special research and development work that has occupied the past three years. A university interested in engineering research work is much preferred. E-2728.

Business Man. Position wanted on staff of financial, underwriting, or analytical organization to investigate commercial technical and scientific soundness of industrial, public utility and other business enterprises. Executive of broad business experience. E-2729.

Mechanical-Electrical Engineer, degrees B. S. and E. E. age 32; married. Experience gained in manufacture, sale, erection and operation of electric furnaces, and in management of electrometallurgical plants. Now with large corporation manufacturing products electrothermally, but seeks change and engagement with smaller organization, preferably one doing some research work. E-2730.

Graduate Engineer (E. E.) age 29; married; five years' experience with large public utility; two years with consulting engineers on appraisals, rate studies, cost work, distribution layouts, and estimating. Desires position with consulting engineers, public utility or manufacturing concern in Ohio or vicinity. E-2731.

Electrical Engineer, graduate M. I. T., married; with ten years experience in active, responsible positions on hydroelectric systems, desires position in West with public service company as engineer or executive; or in like capacity with consulting engineer; or with industrial concern. Experienced in management; meeting the public; sales; operation of plants; systems; apparatus; design and construction. Salary $4000. Reason for moving, desire to locate in West where most of experience was obtained. E-2732.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED MAY 20, 1921

ABBOTT, GORDON A., Maintenance and Construction, Toronto Power Co.; res., 11 Charles St. East, Toronto, Ont., Can.

ABRAHAM, FREDERICK H., Technical Assistant, Bradford Corp., Electricity Dept., Town Hall, Bradford, Yorkshire, England.

ALEXANDER, HUGH GORDON, Power House Maintainence, City of Winnipeg Light & Power Dept., Point du Bois, Manitoba, Can.

ANDERSON, HERBERT M., Tester, Erie Works, General Electric Co., Erie, Pa.

ANGOVE, RAYMOND H., Editor, C-H. Messenger, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

ARMSTRONG, ROBERT B., Supt. of Construction, Wenatchee Valley Gas & Electric Co., Wenatchee, Wash.

ARMSTRONG, WALTER R., Asst. Chief Engineer, Oregon Short Line R. R. Co., 606 Desert News Bldg., Salt Lake City, Utah.

ATKINSON, WILLIAM H., Patent Attorney, General Electric Co., Commercial National Bank Bldg., Washington, D. C.

AVASTY, K. S., Engineer-in-charge (Substation), The Bombay Electric Supply & Tramways Co., Ltd.; res., 49, Kamathipura 5th Lane, Byculla Post, Bombay, India.

BECK, ROBERT C., Engineer, Cutler-Hammer Mfg. Co., New York; res., 37 Woodbine St., Brooklyn, N. Y.

BEGLEY, FRANCIS P., Chief Electrician, James B. Chow & Sons, Coshocton, Ohio.

BERRY, OLIVER F., Tester, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 734 Franklin Ave., Wilkinsburg, Pa.

BLACK, JOHN, Foreman, Canadian Crocker-Wheeler Co., St. Catharines; res., 80 Huron St., Niagara Falls, Ont., Canada.

BLACKWEDEL, GEORGE H., Electrical Draftsman, with Thomas E. Murray, New York; res., 704 98th St., Woodhaven, N. Y.

BLERSCH, ROY E., Industrial Engineer, Century Electric Co., 506 Kirby Bldg., Cleveland, Ohio.

BLISS, MERVIN W., Instructor of Physics, Amherst College; res., 1 Woodside Ave., Amherst, Mass.

BLOSSER, HERMAN G., Designing Engineer, Union Switch & Signal Co.; res., 7129 Schoyer Ave., Swissvale, Pa.

BLUNT, WILLIAM J., Electrical Engineer, Spreydon Borough Council, Christchurch, N. Z.

BONZ, HENRY J., Installation Engineer, Choralcelo Company of America, Chicago; res., 2613 S. 59th Ave., Cicero, Ill.

BORGARDT, JOHN B., Draughtsman, Reliance Electric & Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio.

BOWEN, HIRAM, Inside Constructor, City Light Steam Plant; res., 416 N. 68th St., Seattle, Wash.

BOYCE, HARRY, Checker, Engineering Dept., Western Electric Co., 463 West St.; res., 156 E. 184th St., New York, N. Y.

BRADY, TERENCE M., Superintendent, Central Illinois Public Service Co., Effingham, Ill.

BRAUN, CARL H., Production Manager, Cleveland Electric Motor Co.; res., 1305 W. 105th St., Cleveland, Ohio.

BRESLIN, EDWARD T., District Plant Chief, New England Tel. & Tel. Co., 26 Mechanic St., Worcester, Mass.

BROWN, G. JAY, Chief Electrician, (Pitt River Development), Pacific Gas & Electric Co., Cassel, Calif.

CATES, RICHARD H., Power Engineer, Southern California Edison Co., 3rd & Broadway, Los Angeles, Calif.

CHAICLIN, ABRAHAM, Telephone Engineer, Western Electric Co., Inc.; res., 304 W. 121st St., New York, N. Y.

CHAPMAN, WILLIAM V., Station Meterman, Portland Railway, Light & Power Co.; res., 192½ Grand Ave., Portland, Ore.

CHOW, KOM-PUH, Student Engineer, Bell Telephone of Pennsylvania, 17th & Arch Sts., Philadelphia, Pa.

CHURCH, ARTHUR D., District Manager, Midland Counties Public Service Corp. Santa Maria, Calif.

COFFMAN, RAYMOND N., Electrician, Pure Oil Co., 105 Burt Ave., Newark, Ohio.

COGHLIN, CHARLES C., Electric Contractor, C. C. Coghlin Electric Co., 34 Pearl St., Worcester, Mass.

COLER, CARL S., Manager, Educational Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

CONVERY, JOHN H., Induction Motor Engineering, Canadian General Electric Co., Peterboro, Ont., Canada.

COOLIDGE, WILLIAM H., Jr., President, Luthy Battery Sales Company of New England, Boston; res., Magnolia, Mass.

CORTEN, THEODORE, Jr., Electrical Construction Foreman, General Electric Co.; res., 1400 Cuyler Ave., Chicago, Ill.

COXHEAD, HARRY B., Engineer, Dept. of Development & Research, American Tel. & Tel. Co., 195 Broadway, New York, N. Y

CRONAN, PHILIP G., Gunner (Radio), U. S. Navy, Navy Department; res., 2012 M St., N. W., Washington, D. C.

CURTIS, FREDERICK, Electrician, Detroit Copper & Brass Rolling Mills; res., 7097 Lafayette Blvd., Detroit, Mich.

CURTIS, HARVEY L., Physicist, Bureau of Standards, Washington, D. C.

DALY, CHARLES J., Transmission & Protection Engineer, Southern New England Telephone Co.; res., 132 Foster St., New Haven, Conn.

DAVIS, WILLIAM S., General Meter Inspector, Public Service Electric Co., 826 Terminal Bldg., 80 Park Place, Newark, N. J.

DE MERIT, MERRILL W., Distribution Engineer's Dept., The Detroit Edison Co., 402 Lincoln Bldg., Detroit, Mich.

DEVINEY, ALBERT F., Sales Engineer, The Cutler-Hammer Mfg. Co., 323 S. Michigan Ave., Chicago, Ill.

DOUGHMAN, FERMAN C., Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

DRING, GEORGE S., Telephone & Telegraph Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

DUNNING, SAMUEL G., Service Man, Reliance Electric & Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio.

EARNSHAW, JOHN, Mechanical Superintendent, Warren Mfg. Co., Warren, Rhode Island.

EDOM, WILLIAM E., Shop Foreman, Detroit Copper & Brass Co., Detroit, Mich.

EISAMAN, JAMES R., Night Foreman, Testing Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., Turtle Creek, Pa.

ELLIOTT, JOHN T., Turbine Test, Erie Works, General Electric Co.; res., 453 W. 8th St., Erie, Pa.

*ELTZ, GEORGE J., JR., Manager, Radio Dept. & Consulting Engineer, Manhattan Electric Supply Co., 17 Park Place, New York, N. Y.

EWART, JAMES B., Engineer, 1st Battalion, N. M. N. Y., S.S. *Granite State*, 97th St. & North River, New York, N. Y.

FESSENDEN, GEORGE R., Service & Publicity Engineer, North East Electric Co., 348 Whitney St., Rochester, N. Y.

FICK, ERNEST, General Equipment Foreman, American Tel. & Tel. Co., Division No. 4, 311 W. Washington, St., Chicago, Ill.

FITZ, J. ALLEN, Compass Engineer, Sperry Gyroscope Co., 40 Flatbush Ave. Extension; res., 19 Fort Greene Place, Brooklyn, N. Y.

FITZPATRICK, ROBERT W., Electrical Inspector, Georgia Railway & Power Co., 456 Elec. & Gas Bldg., Atlanta, Ga.

FLOWERS, WILLIAM E., Engineering Estimator, Georgia Railway & Power Co., 456 Electric & Gas Bldg., Atlanta, Ga.

FRANCIS, FRANCIS, Supervisor, Substation Equipment, Bell Telephone Company of Canada, 33 Temperance St., Toronto, Ont.

FREIBURGHOUSE, EDWARD H., Designing Electrical Engineer, General Electric Co.; res., 630 Brandywine Ave ,Schenectady, N. Y.

FULLER, HOWARD H., Instructor in Electrical Engineering, University of Wisconsin; res., 120 W. Wilson St., Madison, Wis

GEYER, ARTHUR N., Maintenance Engineer, Utah Power & Light Co., Salt Lake City, Utah.

GOLDFARB, GEORGE, Draftsman, Cutler-Hammer Mfg. Co.; res., 556 Fox St., New York, N. Y.

GOODALL, ARTHUR S., Tester, General Electric Co., W. Lynn; res., 78 Park St., Lynn, Mass.

GOODMAN, SHIRLEY H., Sales Manager, E. L. Knight & Co., 449 Washington St., Portland, Ore.

GRAHAM, FRANK H., Engineer, Western Electric Co., Inc., 463 West St., New York, N. Y.

GRIMSHAWE, JOSEPH L., Asst. Engineer, Charleston Consolidated Railway & Lighting Co., Charleston, S. C.

GRUBBS, GROVER C., General Shop Manager, Howell Electric Motors Co.; res., 221 N. Barnard St., Howell, Mich.

HANNIBAL, ENOCH R., Supt., Interstate Utilities Co., 612 Columbia Bldg., Spokane, Wash.

HARVEY, WALTER, Supervising Inspector, Winding Dept., Westinghouse Electric & Mfg. Co.; res., 221 2nd St., Newark, N. J.

HEITNER, ALFRED C. L., Engineering Dept., Western Electric Co., 463 West St., New York; res., 356 Onderdonk Ave., Brooklyn, N. Y.

HELLBORN, AXEL V., Engineering Man agcr Otis Elevator Co., 11th Ave. & 26th St. New York, N. Y.

HEMSTREET, JOHN GROVER, Supt. of Operation, Consumers Power Co., 224 W. Main St., Jackson, Mich.

HERBIG, RUDOLPH O., Sales Engineer, Reliance Electric & Engineering Co., 708 Traction Bldg., Cincinnati, Ohio.

HERN, GEORGE P., Engineering Asst., Public Service Electric Co., Newark; res., 277 Highland Ave., Passaic, N. J.

HILL, ROBERT N., Design Draftsman, Roth Bros. & Co.; res., 3418 Fulton St., Chicago, Ill.

HOLLINGSWORTH, FRED L., Draftsman, Engineering Dept., Georgia Railway & Power Co.; res., 199 N. Moreland Ave., Atlanta, Ga.

HUNTER, CHARLES H., Inspector & Salesman, Penn. Utilities Co., Easton; res., 1124 W. Market St., Pottsville, Pa.

HUNTING, RALPH W., In Charge of Arizona Territory, Pacific States Electric Co., 811 N. 1st St., Phoenix, Ariz.

*HYMAN BENZION, Teacher, University of Toronto; res., 22 St. Andrew St., Toronto. Ont.

INGLES, HARRY C., Major, Signal Corps, U.S. Army, Military Dept., Univ. of Minnesota, Minneapolis, Minn.

JACK, HUGH, Designing Engineer, British Thomson-Houston Co., Rugby, Eng.

JACOBSON, ALFRED T., Student, Graduate Course, Allis-Chalmers Mfg. Co.; res., 553 64th Ave., W. Allis, Wis.

JAEGER, WALTER H., Assistant, Transformer Design, Canadian General Electric Co., Peterboro, Ont., Canada.

JAQUES, ARTHUR, New Building Agent, United Electric Light & Power Co., 130 E. 15th St., New York, N. Y.

KAMEYAMA, TORU, Electrical Engineer, South Manchuria Railway Co.; 1 Union St., Schenectady, N. Y.

KAUFFMAN, L. W., Electrician, Penna Water & Power Co.; res., Central Y. M. C. A., Baltimore, Md.

KEERS, JOHN K., JR., Electrical Engineer, Public Service Commission, 1st Dist., 49 Lafayette St., New York; res., 224 81st St., Brooklyn, N. Y.

*KELLEHER, JAMES, Demonstrator, Dept of Electrochemistry, University of Toronto, Toronto, Ont., Canada.

KELLER, EMANUEL, Instrument Inspector, Westinghouse Elec & Mfg. Co.; res., 75 Runyon St., Newark, N. J.

KELLEY, LEO A., Carrier Systems Development Dept., Western Electric Co., 463 West St., New York, N. Y.

KELLY, ALBERT G., Tester, Otis Elevator Co.; res., 263 Elm St., Yonkers, N. Y.

KEMP, WILLIAM B., Asst. Traffic Engineer, Michigan State Telephone Co.; res., 4529 Commonwealth Ave., Detroit, Mich.

KENT, JOSEPH B., Foreman, Electrical Construction, San Francisco Div., Pacific Gas & Electric Co.; res., 3512 23rd St., San Francisco, Cal.

KING, CECIL W., Shift Engineer, Radio Corporation of America, New Brunswick, N. J.; res., 50 Bond St., Port Richmond, N. Y.

KIRCHNER, LESTER F., Secretary & Treasurer, Modern Electric Shop; res., 1316 Longfellow St., N. W., Washington, D. C.

KLINE, WILLIAM H., Division Supervisor of Special Contract Service, American Tel. & Tel. Co.; res., 4419a Clarence Ave., St. Louis, Mo.

KLOEFFER, ROYCE G., Associate Professor of Electrical Engineering, Kansas State College, Manhattan, Kans.

KRITZMARHER, HARRY L., Asst. Foreman, Instrument Test Dept., Westinghouse Elec. & Mfg. Co.; res., 6a Milford Ave., Newark, N. J.

LANG, JOHN J., Electrician, Detroit Copper & Brass Rolling Mills; res., 6528 Whitewood Ave., Detroit, Mich.

LANOUE, ALEXANDER J. R., Patent Engineer, Northern Electric Co., Ltd.; res., 27 Cote St., Montreal, Que.

LAUDERDALE, FERNANDO S., Tester, Westinghouse Elec. & Mfg. Co., 510 Todd St., Wilkinsburg, Pa.

LAVEN, HARRIS, Electrician, D. P. Robinson & Co., Turtle Creek, Pa.; res., 1543 E. 10th St., Brooklyn, N. Y.

LAWSON, DENHART K., Draftsman, Pittsburgh Transformer Co., Pittsburgh; res., 6541 Watt Ave., Ben Avon, Pa.

LEE, T. JULIUS B., Chief Electrician, Baraqua Sugar Co., Baraqua, Cuba.

LESLIE, FRED A., Electrical Testman, Consolidated Gas, Electric Light & Power Co., Baltimore, Md.

LEVY, CHARLES H., Jr., Otis Elevator Co., 26th St. & 11th Ave., New York, N. Y.; res., 137 S. 11th St., Newark, N. J.

LINDSAY, WILLIAM H., Estimator, Allegheny County Light Co.; res., 334 Sheridan Ave., E. E., Pittsburgh, Pa.

LIST, VLADIMIR, Professor of Electrical Engineering, Brno Technical University, Brno, Czechoslovakia.

LOUX, RAYMOND A., Electrical Engineer & Manager, Nashwauk Electrical Co., Nashwauk, Minn.

LOVE, ROBERT M., Street Lighting Specialist, Canadian General Electric Co., Toronto, Ont., Canada.

LUERSSEN, GEORGE A., Electrical Designer, Public Service Electric Co., Newark, N. J

LYNCH, JOHN P., Telephone Specialist, Western Electric Co., 385 Summer St., Boston; res., Roslindale, Mass.

*MACLEAN, IAN M., Testing Dept., Canadian General Electric Co., Peterboro, Ont.; res., Strathlorne, N. S.

MALWITZ, RAY C., Student & Foreman, American Railway Express, 3232 Michigan Ave., Chicago, Ill.

MANCHESTER, MARK D., Electrical Superintendent, Yukon Gold Co., Dawson, Y. T.

MARKS, ALEXANDER, Engineer, Otis Elevator Co., 250 11th Ave., New York, N. Y.

MARTINA, S. WILLIAM, Foreman, Electrical Testing Dept. & Tool Room, Johnson Service Co.; res., 910 Locust St., Milwaukee, Wis.

MAZDA, CHOSABURO, Research Scholarship, Kyoto Imperial University; res., Nishiteramachi Gojo-Agaru, Chudeji, Kyoto, Japan.

McALLISTER, JAMES H., Asst. City Electrician, Electrical Dept., City of Cambridge; res., 9 Arnold Circle, Cambridge, Mass.

McCLUNG, DONALD R., Electrical Draftsman, Pacific Power & Light Co., 409 Gasco Bldg., Portland, Ore.

McGEE, P. A., General Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., Westinghouse Club, Wilkinsburg, Pa.

McGILLIVRAY, HARRY, Electrical Contractor, 508 W. 23rd St., New York, N. Y.

McLEAN, ARTHUR M., Journeyman Wireman, 425 Stark St.; res., 871 Clinton St., Portland, Ore.

McLEAN, CHARLES C., Journeyman Wireman, Sanders Electric Co.; res., 871 Clinton St., Portland, Ore.

MERCIER, CYRIL A., Construction Man, Scranton Electric Co.; res., 532 Adams St., Scranton, Pa.

MICHAELSON, ARTHUR R., Instructor, New York Electrical School, 39 W. 17th St.; 464 W. 34th St., New York, N. Y.

MILLER, GEORGE M., Supt., Elec. Dist. & Constr. Dept., Louisville Gas & Electric Co., 311 W. Chestnut St., Louisville, Ky.

MILLER, WALTER RAY, Maintenance & Construction Electrician, Erie Works, General Electric Co.; res., 1054 Ranken Ave., Lawrence Park, Erie, Pa.

MILNE, WINFORD G., Factory Manager, N. Slater Co., Ltd., Sydney St., Hamilton, Ont.

MINTZ, JAY J., Supervising Designer, Guggenheim Bros., 120 Broadway; res., 635 W. 171st St., New York, N. Y.

MITCHELL, EARLE A., Efficiency Engineer, Habirshaw Electric Cable Co.; res., 785 Warburton Ave., Yonkers, N. Y.

MOFFAT, WILLIAM R., Supervisor, Central Office Equipment, Bell Telephone Co.; res., 1 Bowden Ave., Toronto, Ont., Canada.

MOHR, FRANKLIN, Research Engineer, Western Electric Co., 463 West St., New York, N. Y.

MOIR, DANIEL F., Chief Electrician, C. H. Wills & Company, Marysville, Mich.

MONTGOMERY, ROBERT G., Branch Manager, Westinghouse Lamp Co., 121 E. Baltimore St., Baltimore, Md.

MOORE, CHARLES A., Supt., Electrical Dept., Berwind-White Coal Mining Co.; res., 1602 Somerset Ave., Windber, Pa.

MOSER, WALTER A., Branch Manager, Westinghouse Elec. & Mfg. Co., 1212 Walker Bank Bldg., Salt Lake City, Utah.

MURRAY, BURNETT M., Asst. Engineer, English Electric Co., Ltd.; Messrs. Jardine, Mathesons Co., Ltd., 8a Yuen Ming Yuen Road, Shanghai, China.

MURRAY, JOHN S., Chief Electrician, Follansbee Bros. Co., Toronto, Ohio.

MYERS, DON E., Division Engineer, Central Illinois Public Service Co., Beardstown, Ill.

NASH, ALBERT E., Wireman, General Electric Co.; res., 1020 Smithson Ave., Lawrence Park, Erie, Pa.

NORTON, FREDERICK W., General Tester, New York Edison Co., New York; res., 121 Anderson Ave., Port Richmond, S. I., N. Y.

O'BRIEN, HARRY A., Foreman, Brooklyn Edison Co., Inc., 360 Pearl St.; res., 1218 Park Place, Brooklyn, N. Y.

O'NEEL, CLARENCE M., Electrician, Kennecott Copper Co., Latouche, Alaska.

ORTON, H. C., General Manager, Electric Utility, McGregor, Iowa.

OSWALD, EMIL U., Erecting Engineer, Allis-Chalmers Mfg. Co.; res., 2811 North Ave., Milwaukee, Wis.

OTTERSON, HENRY A., Sales Manager, Ridgway Dynamo & Engine Co.; res., 302 Metoxet St., Ridgway, Pa.

PAESEL, CARL M., Asst. Chief Engineer, Choralcelo Company of America, Chicago; res., 2723 So. 60th Court, Cicero, Ill.

PARK, J. CALVIN, Production Engineer, Otis Elevator Co.; res., 84 Ludlow St., Yonkers, N. Y.

PARKER, GEORGE S., Instructor, Dept. of Electrical Engineering, University of Illinois, Urbana, Ill.

PATRICK, MATTHEW J., Electrician, J. Schwerin, Ellison & Prospect Sts.; res., 105 Pine St., Paterson, N. J.

PERRY, HAROLD D., Chief Draftsman, Union Gas & Electric Co., West End Station, Cincinnati, Ohio.

PERRY, RUSSELL E., Telephone Engineer, Western Electric Co., 463 West St., New York, N. Y.

PETRIK, JOHN J., Educational Work, Michigan State Telephone Co.; res., 2254 Taylor Ave., Detroit, Mich.

PLANT, GEORGE F., General Foreman, Trouble & Signal Div., The Milwaukee Electric Railway & Light Co., Milwaukee, Wis.

PULLMAN, WILLIAM Electrician, Westend Chemical Co., Westend, Calif.

QUAAS, RICHARD T., Dwight P. Robinson Co., Inc.; res., 2154 Crotona Ave., New York, N. Y.

QUENTIN, GEORGE W., Sales Engineer, Duquesne Light & Power Co., 435 6th Ave., Pittsburgh, Pa.

REIBER, ALBERT H., Sales Engineer, Kleinschmidt Electric Co., 36 Flatbush Ave. Extension, Brooklyn; res., 1317 Plimpton Ave., New York, N. Y.

RHEINGOLD, LEO C., Junior Electrical Engineer, Transit Commissioner, State of New York; res., 997 Union Ave., New York, N. Y.

RHODES, JAMES H., Electrical Contractor, 59 Jersey St., New Brighton, S. I., N. Y.

ROBERTS, SAMUEL N., Electrical & Mechanical Supt., Atlantic Steel Co., Atlanta, Ga.

ROUCI, VICTOR L., Laboratory Supervising Mechanic, Western Electric Co., 463 West St., New York, N. Y.

RUISCH, EDWARD, Local Manager, Iowa Light, Heat & Power Co., Sanborn, Iowa.

RUSSELL, HENRY C., Apprentice, Electrical Handyman, Allis-Chalmers Mfg. Co.; res., 545 65th Ave., West Allis, Wis.

SHEPARD, HERMAN A., Supt. of Telegraph, New York, New Haven & Hartford R. R., New Haven, Conn.

SIMKINS, EUGENE S., Sales Engineer, Standard Underground Cable Co., 700 Westinghouse Bldg., Pittsburgh, Pa.

SIMPSON, FRANK M., Engineer of Fundamental Plans & Distribution, Bell Telephone Company of Canada, Montreal Can.

SMITH, H. G., Meter Supt., The Springfield Light, Heat & Power Co., Springfield, Ohio.

SMITH, WILLARD H., Asst. Foreman, Electrical Maintenance & Construction, General Electric Co.; Erie; res., 3612 Main St., Lawrence Park, Erie, Pa.

SNYDER, WILLIAM E., Engineering Asst., New York Telephone Co.; res., 40 E. 40th St., New York, N. Y.

SOBOSLAY, GODFREY G., 1st Class Electrician Brooklyn Edison Co.; res., 320 49th St., Brooklyn, N. Y.

SPARKES, HARRY P., Electrical Engineer, Supply Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

STALZER, FRANK, Electrician, Rockwood Silica Co., Rockwood, Mich.

STEVENS, J. WEBSTER, Manager, Modern Electric Shop, 1411 U St., N.W., Washington, D. C.; res., Arlington, Va.

STEVENS, KYLE M., Electrical Testing, Union Gas & Electric Co., West End Station; res., 536 Howell Ave., Cincinnati, Ohio.

STEWART, PAUL, Electrical & Steam Power Apparatus, 1st National Bank Bldg., Cincinnati, Ohio.

STEWART, STANLEY G., Manager, Edison Electric Appliance Co., Service Station, 412½ Stark St., Portland, Ore.

STRYKER, CLINTON E., Asst. Professor of Electrical Engineering, Armour Institute of Technology, 33rd & Federal Sts., Chicago, Ill.

STUMCKE, CHARLES E., JR., Chief Electrical Draftsman, The Lake Torpedo Boat Co., Milford, Conn.

SULLIVAN, R. W., Supt., Avalon Telephone Co., Ltd.; res., 201 Duckworth St., St. Johns, Newfoundland.

TANNENBAUM, ALTON, Engineering Dept., New York Edison Co.; res., 894 E. 163rd St., New York, N. Y.

TAMITARO, TATSUMI, Designing Engineer, Mitsui Miike Engineering Works, Omutashi, Fukuokaken, Japan.

THOMPSON, WILLARD W., Engineer, Hixon Electric Co., 308 Dover St., Boston, Mass.

TISSINAY, KALMAN C., Foreman, Instrument & Relay Test Dept., Westinghouse Elec. & Mfg. Co., Newark, N. J.

WALLS, RAY B., Manager, Peninsula Electric Co., 109 S. Jersey St., Portland, Ore.

WARD, AARON, 17 Stratford Place, Newark, N. J.

WASHINGTON, GEORGE L., Sales Engineer, Westinghouse Electric International Co., Havana, Cuba.

WATERMAN, HARRISON B., Sales Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

WEEKS, NORMAN E., Asst. Division Toll Engineer, New York Telephone Co., Brooklyn; res., 78 Liberty Ave., Rockville Centre, N. Y.

WEEKS, WALTER H., Illuminating Engineer, Bryan-Marsh Division, General Electric Co., 33 Union Square, New York, N. Y.

WEIR, HARRY E., Sales Manager, Nyelec Switchboard Co., 430 E. 53rd St.; res., 1326 Fulton Ave., New York, N. Y.

WEISS, SAMUEL, Engineering Draftsman Hatzel & Buehler; res., 590 E. 138th St. New York, N. Y.

WIEDMANN, MILTON L., Laboratory Asst., Pacific Gas & Electric Co., San Francisco; res., 3525 Peralta Ave., Oakland, Cal.

WIGHT, FRANK J., Engineer, Utah Power & Light Co.; res., 281 Kelsey Ave., Salt Lake City, Utah.

WILKE, MAX, Meter Supt., Ohio Power Co., Steubenville and E. Liverpool; res., 1345 Wellesley Ave., Steubenville, Ohio.

WILSON, HAROLD N., Erecting Engineer, Allis-Chalmers Mfg. Co.; res., 3619½ Sycamore St., Milwaukee, Wis.

WILSON, WILLIAM H., Installation Engineer, Colombo Electric Light & Tramways Co., Boustead Bros., Colombo, Ceylon.

WIMMER, ELMER P., Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 818 Hill Ave., Wilkinsburg, Pa.

WINCHESTER, LESLIE V., Engineer, Bucyrus Co., South Milwaukee, Wis.

WOLFF, BOYD L., Wolff Electric Works, 65 W. 9th St., Portland, Ore.

WOOD, EDWIN D., Electrical Operating Engineer, Louisville Gas & Electric Co., 311 W. Chestnut St., Louisville, Ky.

WOOD, LEWIS P., Electrical Engineer, Diehl Mfg. Co., Elizabeth, N. J.

WOOD, THOMAS B., Electrical Tester, B. F. Goodrich Co., Akron, Ohio.

WORTHAM, HENRY, Jr., Substation Operator, Public Utility Co.; res., 803 Lakeside Place, Chicago, Ill.

WORTMAN, JOSEPH C., Manager of Works, Novelty Incandescent Lamp Co., Erie Ave., St. Marys, Penn.

WORTMAN, RAYMOND B., Manager, Electrical Supply Shop, 31 Downer St., Baldwinsville, N. Y.

WRIGHT, M. M., Electrical Engineer, Christchurch Tramway; res., 12 Mayfield Ave., Christchurch, N. Z.

YANAGISAWA, YOSHIJIRO, Designing Engineer of Switchgears, Mitsubishi Zosen Kaisha, Kobe, Japan.

YOSHIO, TSUZUKI, Designing Engineer, Mitsui Miike Seisakusho, Omuta, Fukuokaken, Japan.

YOUNG, ARTHUR, Instructor, Federal Board, Vocational School, College of the City of New York; res., 501 Shepherd Ave., Brooklyn, N. Y.

YUNCK, WILLIAM K., W. K. Yunck Sales Co., 3149 Woodward Ave., Detroit, Mich.

Total 222.

SCHMIDT, SIGURD H., Chief Draftsman & Plant Electrical Engineer, National Conduit & Cable Co., 163 Warburton Ave., Yonkers, N. Y.

STUART, LEMUEL M., Electrical Foreman, Ford Instrument Co., 80 Lafayette St., New York; res., 1448 E. 10th St., Brooklyn, N. Y.

TABER, RAY HOWARD, Electrical Instructor, San Diego High School, San Diego; res., 659 Del Mar Ave., Chula Vista, Cal.

THOMPSON, J. COX, Engineer, United Electric & Valley Railways Co., Lemoyne, Pa.

WARD, BALDWIN D., Consulting Electrical & Mechanical Engineer, 76 11th St., Oakland, Cal.

WEICKER, WILLIAM, Dr. of Engineering, Hermsdorf S.-A., Germany.

MEMBERS ELECTED MAY 20, 1921

AUSTIN, BASCUM O., Section Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 205 Franklin Ave., Wilkinsburg, Pa.

BATTYE, BASIL C., Engineer-in-charge, Sutlej River Hydro-Electric Project, Rupar, Ambala Dist.,Punjab, India.

BLACK, HOMER S., Asst. General Manager, Westinghouse Lamp Co., 165 Broadway, New York, N. Y.

CHERRY, TALMADGE C., Vice-President & General Manager, Rochester & Syracuse Railroad Co., 500 Syracuse Savings Bank Bldg., Syracuse, N. Y.

CHRISTENSEN, CHRISTEN, Chief Engineer, Electrical Engineers Equipment Co., 35 S. Desplaines St., Chicago, Ill.

CLARK, HAROLD M., Dist. Inspector, Electricity & Gas Inspection Service, 66 Victoria St., Toronto, Ont., Canada.

DAY, IRVIN W., Vice-President, The Connecticut Light & Power Co.; res., 12 1st Ave., Waterbury, Conn.

FORTIER, CHARLES L., Consulting Engineer, Johnson Service Co., 149 Michigan Ave., Milwaukee, Wis.

FUKUNAKA, SATARO, Chief Engineer, Nippon Electric Power Co., Imabashi, Osaka, Japan.

HAGELIN, BORIS C. W., Electrical Engineer, Standard Oil Co., Elizabeth, N. J.

HENTON, STUART C., Superintendent of Meters, Northern Ohio Traction & Lihgt Co., Terminal Bldg., Akron, Ohio.

HERD, PHILIP, Partner, Messrs, Rice, Wilson & Herd; res., Rock Ridge Road, Parktown, Johannesburg, S. Africa.

HILL, RAYMOND P., Manager of Maintenance, Crocker-McElwain Co.; Chemical Paper Mfg. Co., Holyoke, Mass.; res., 3410 Mountain Ave., El Paso, Texas.

KINTZING, R. TENCH, Control Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 828 Ramsey Ave., Wilkinsburg, Pa.

LAMBE, ALFRED B., Engineer, Dominion Power Board, Ottawa,nt O., Canada.

LEWIS, DU GUE K., Electrical Engineer, Winnipeg Electric Railway Co., Winnipeg, Man.

MANWARING, ROY A., Superitenndent, Dwight P. Robinson & Co., Seward, Pa.

RIDDICK, ARCHIE G., Electrical Engineer, Gulfport & Miss. Coast Traction Co., Gulfport, Miss.

SMITH, RODERICK N., District Engineer, Fred T. Ley & Co., Inc., Fairmount, W. Va.

SYLVESTER, J. WILSON, Supt., A C. & Arc Underground Lines, The Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.

TODD, VICTOR H., Meter Test Engineer, Westinghouse Elec. & Mfg. Co., Newark; res., 427 Parkinson Terrace, Orange, N. J.

TRANSFERRED TO GRADE OF MEMBER MAY 20, 1921

AMOS, WALTER L., Electrical Engineer, Engineering Dept., Hydro-Electric Power Commission of Ontario, Toronto, Ont.

BEACH, ROBIN, Acting Head of Electrical Engineering Dept., Polytechnic Institute, Brooklyn, N. Y.

BOND, JOHN MILTON, Head of Car Equipment Test Dept., Interborough Rapid Transit Co., New York.

CORNELL, ROBERT L., Vice-President, Industrial Supply & Engineering Co., Lexington, Ky.

CRICHTON, LESLIE N., Section Engineer, Supply Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

DELLENBAUGH, FREDERICK S., Jr., Secretary, Research Division, Electrical Engineering Dept., Massachusetts Institute of Technology, Cambridge, Mass.

FAY, FRANK H., Supervisor, Printing Telegraph Service, American Telephone & Telegraph Co., New York, N. Y.

FLOOD, HENRY, JR., Engineer-Secretary, Superpower Survey, U. S. Geological Survey, New York.

GAYLORD, TRUMAN P., Acting Vice-President, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

GILLILAND, CLARENCE R., Manager, Railway & Power Depts., Westinghouse Elec. & Mfg. Co., Cincinnati, O.

HERR, EDWIN M., President, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

HOFFMAN, A. J., Electrical Engineer, Lockwood Greene & Co., Chicago, Ill.

RYLANDER, JOHN L., Electrical Engineer, Motor Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

SHREEVE, HERBERT E., Telephone Engineer, Western Electric Co., New York, N. Y.

SPENCER, BURT K., Assistant Engineer with A. G. Wood, Philadelphia, Pa.

THURSTON, ERNEST B., Electrical Engineer, Haughton Elevator & Machine Co., Toledo, Ohio.

TOEPPEN, MANFRED K., Appraisal Engineer Michigan Public Utilities Commission, Detroit, Mich.

TRIPLETT, HUGH A., Electrical Construction Engineer, Midland, Pa.

WOOD, HENRY BLAKE, Electrical Engineer, Stone & Webster, Inc., Boston, Mass.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held May 13, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

MORELAND, EDWARD L., Partner & Manager, Jackson & Moreland, Boston, Mass.

WALLER, ALFRED E., Chief Engineer, Ward Leonard Electric Co., Mount Vernon, N. Y.

WEICHSEL, HANS, Chief Designing Engineer, Wagner Electric Co., St. Louis, Mo.

To Grade of Member

BINGHAM, ALBERT R., Superintendent, Canadian Light & Power Co., Montreal, Que.

CASE, RALPH E., Works Manager, John Johnson Co., Brooklyn, N. Y.

CLEGG, T. HERBERT, Assistant to Otto M. Rau, Philadelphia, Pa.

DANIELS, RAYMOND S., Electrical Engineer, Washington Water Power Co., Spokane, Wash.

DAVIS, ERNEST W., Asst. Electrical Engineer, Simplex Wire & Cable Co., Cambridge, Mass.

FIELD, FRANK E., Electrical Engineer, Western Electric Co., New York, N. Y.

FLEMING, DAVID B., Asst. Electrical Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

GEE, PAUL M., Foreman, Electric Drafting Division, Brooklyn Edison Co., Brooklyn, N. Y.

GERHARDT, CARL L., Electrical Engineer, United Verde Copper Co., Clarkdale, Ariz.

HARBAUGH, WILLIAM M., Engineer, Lehigh Portland Cement Co., Allentown, Pa.

HARTSHORNE, WILLIAM B., Service Engineer, Public Service Electric Co., Newark, N. J.

HILL, ARTHUR ST. J., Associate Professor of Electrical Engineering, University of Maine, Orono, Me.

JAMES, HAMILTON D., Manager, Industrial Division, Westinghouse Electric & Mfg. Co., Cincinnati, O.

JEFFERY, J. J., Asst. Electrical Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

KLAUDER, LOUIS T., Consulting Engineer, Philadelphia, Pa.

LYTHGOE, JOSEPH, City Electrical Engineer, Christchurch, New Zealand.

McAFEE, W. KEITH, Foreman, Sunnyside Engine House, Pennsylvania Railroad, New York, N. Y.

MALTHA, GERARD S., Chief Designing & Estimating Engineer, Ebro Irrigation & Power Co., Barcelona, Spain.

PALMER, HARRY R., Vice-President & General Manager, Harrisburg Light & Power Co., Harrisburg, Pa.

ROMANOVSKY, CHARLES, Commercial Engineer, General Electric Co., Schenectady, N. Y.

SCHIEFER, HENRY J., Jr., President & Treasurer, Schiefer Electric Co., Inc., Rochester, N. Y.

SCHWARTING, HARRY F., Assistant to Chief Electrical Engineer, American Car & Foundry Co., St. Louis, Mo.

STEVENSON, FRANCIS L., Chief Electrical Engineer, International Harvester Co., Chicago, Ill.

WYATT, FRANCIS D., Electrical Engineer, Union Gas & Electric Co., Cincinnati, O.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before June 30, 1921.

Acheson, Harry H., Bluefield, W. Va.
Adams, Charles H., Kenton, Ohio.
Adkerson, Branch O., Key West, Fla.
Ames, Chester E., Boston, Mass.
Anderson, O. W., Connellsville, Pa.
Angle, Wesley M., Rochester, N. Y.
Archer, E. G., Toronto, Ont.
Ayres, Lee T., Salt Lake City, Utah.
Back, John J., Waterbury, Conn.
Bahnson, G. Frederick R., Allentown, Pa.
Bindshedler, Theodore S., (Member), Philadelphia, Pa.
Bird, Jewett D., (Member), Waterbury, Conn.
Black, Donald C., Hyrum, Utah.
Black, Howard M., Toronto, Ont.
Blaisdell, Guy M., Boston, Mass.
Bockus, Gerald L., Sherbrooke, Que.
Booth, George G., Boston, Mass.

STUDENTS ENROLLED MAY 20, 1921

13263 Walter, Thomas., School of Engineering of Milwaukee.
13264 DeVoe, Arthur A., Rensselaer Poly. Inst.
13265 Garbacz, George, School of Engineering of Milwaukee
13266 Beauman, L. Roy, University of Illinois
13267 Farnsworth, Hugh D., Ohio Northern Univ.
13268 Glick, Arthur A., Case School of Applied Science
13269 Le Blanc, Charles W., Carnegie Institute of Technology
13270 Menzel, Herman, New York Elec. School
13271 Blodgett, Randolph C., New Hampshire State College
13272 Cox, Newton, New Hampshire State Coll.
13273 Steed, Paul B., Carnegie Inst. of Tech.
13274 Myers, Roland B., Iowa State College
13275 Boboerg, Raymond W., Iowa State Coll.
13276 Wilson, Embree D., Iowa State College
13277 Henderson, F. Murray, Iowa State Coll.
13278 Lemen, Foster M., Iowa State College
13279 Ashton, Laston E., Toronto Central Technical School
13280 Mackay, William M., Toronto Central Technical School
13281 McMurray, James L., Union College
13282 Sheals, Vincent A., Union College
13283 Bricks, Harry M., Union College
13284 Brubaker, Orville K., Kansas State Agr. College
13285 Breslau, Harold, Johns Hopkins Univ.
13286 Muhlmeister, Albert A., Cooper Union
13287 Brown, Paul L., New York Elec. School
13288 Morton, Arthur S., School of Engineering of Milwaukee
13289 Martin, Clarence R., School of Engineering of Milwaukee
13290 Spaulding, George W., Mass. Inst. of Tech.
13291 Kovar, Paul, Kansas State Agr. College
13292 Reazin, George H., Kansas State Agr. Coll.
13293 Garman, F. R., University of Pittsburgh
13294 Freund, John J., Newark Technical School
13295 Hess, Charles W., Johns Hopkins Univ.
13296 Sittel, Virgil, Oklahoma A. & M. College
13297 Baughman, LeRoy B., Johns Hopkins University
13298 Koester, Henry F., Cooper Union
13299 Young, Howard E., Pratt Institute
13300 Watson, Dwight, Univ. of Washington
13301 Roos, Albert H., Univ. of Washington
13302 Borman, Ernest E., University of Wash.
13303 McKown, Paul M., Kansas State Agr. Col.
13304 Gibbs, Benj. F., Montana State College
13305 Fitzgerald, Edgar J., University of Kansas
13306 Hatheway, Donald H., Mass. Inst. of Tech.
13307 Peckham, Joseph W., Rhode Island State College
13308 Greene, Marcus C., Georgia School of Technology
13309 Husemeyer, William W., Montana State College
13310 Owenhouse, Manuel J., Univ. of California
13311 Riggs, R. A., Univ. of California
13312 King, Kenneth A., University of Southern California
13313 Fairchild, Charles V., University of Southern California
13314 Phegley, M. Melvin, University of Southern California
13315 Soo-Hoo, Peter, University of Southern California
13316 Albert, Edmond, Univ. of Southern Calif.
13317 Bailey, H. Morle, University of Southern California
13318 Willits, Ellis J., University of Southern California
13319 Walta, Joseph, Univ. of Southern Calif.
13320 Rowley, Robert E., University of Southern California
13321 Bailey, Gilbert S., University of Southern California

13322 Close, Gerald A., Pratt Institute
13323 Drews, William F., Lewis Institute
13324 Adams, Robert M., Stevens Inst. of Tech.
13325 Hasenpflug, University of Illinois
13326 Tomlin, Arthur R., Toronto Central Technical School
13327 Forster, Robert G., Toronto Central Technical School
13328 Hambrook, Richard E., California Institute of Technology
13329 Hart, Glen J., Montana State College
13330 Berg, William F., Jr., School of Engineering of Milwaukee
13331 King, Stuart N., School of Engineering of Milwaukee
13332 Kaplan, Aaron, City College of New York
13333 Brennan, Adam H., Pratt Institute
13334 Burt, Jairus F., Pratt Institute

Wm. A. Del Mar, J. Franklin Meyer, A. H. Timmerman,
F. M. Farmer, Taliaferro Milton, Philip Torchio,
H. W. Fisher, R. W. E. Moore, W. K. Vanderpoel,
F. C. Hanker, R. B. Williamson,

EDISON MEDAL COMMITTEE

Appointed by the President for term of five years

(Term expires July 31, 1921.)
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.
(Term expires July 31, 1922.)
Comfort A. Adams, Chairman, L. A. Ferguson, S. W. Stratton.
(Term expires July 31, 1923.)
Frederick Bedell, L. T. Robinson, Calvert Townley.
(Term expires July 31, 1924.)
E. D. Adams, H. H. Barnes, Jr. B. G. Lamme.
(Term expires July 31, 1925.)
H. M. Byllesby, D. E. Drake, W. L. R. Emmet.

Elected by the Board of Directors from its own membership for term of two years.

(Term expires July 31, 1921.)
G. Faccioli, W. A. Hall, Wilfred Sykes.
(Term expires July 31, 1922.)
L. E. Imlay, F. D. Newbury, W. I. Slichter.

Ex-Officio

A. W. Berresford, President, George A. Hamilton, Treasurer,
F. L. Hutchinson, Secretary.

RESEARCH COMMITTEE

F. B. Jewett, Chairman, 463 West St., New York
C. A. Adams, W. A. Del Mar, E. W. Rice, Jr., B. A. Behrend, D. C. Jackson, C. E. Skinner, Frederick Bedell, P. Junkersfeld, Elmer A. Sperry, E. B. Craft, A. E. Kennelly, S. S. Wheeler, E. E. F. Creighton, Bancroft Gherardi, J. B. Whitehead, H. P. Davis, L. F. Morehouse, W. R. Whitney

SPECIAL COMMITTEES

GEOGRAPHICAL DIVISIONS AND ELECTION PROCEDURE

H. H. Barnes, Jr., Chairman, 120 Broadway, New York, N. Y.
Wills Maclachlan, L. F. Morehouse, F. L. Hutchinson, Paul Spencer.

SUPER-POWER SYSTEM

W. S. Murray, Chairman, 709 Sixth Ave., New York, N. Y.
H. V. Bozell, Malcolm MacLaren, D. B. Rushmore, H. W. Buck, William McClellan, Charles F. Scott, J. W. Lieb, C. S. Ruffner, Percy H. Thomas

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

Philip Torchio, Chairman, 124 E. 15th St., New York, N. Y.
R. H. Burcher, L. E. Imlay, D. C. Jackson, W. S. Gorsuch, S. R. Inch, Wm. McClellan, L. G. Ireland,

EDUCATIONAL

C. E. Magnusson, Chairman, University of Washington, Seattle, Wash.
Edward Bennett, C. S. Howe, H. W. Price, C. R. Dooley, L. F. Morehouse, R. F. Schuchardt, O. J. Ferguson, J. C. Parker, W. R. Work, C. H. Pfeif,

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 85 Devonshire St., Boston, Mass.
A. S. McAllister, Secretary, 248 West 76th Street., New York, N. Y.
B. L. Barns, W. J. Foster, A. C. Lanier, James Burke, H. U. Hart, F. D. Newbury, Alexander Churchward, V. Karapetoff, Philip Torchio, G. Faccioli, B. G. Lamme, R. B. Williamson,

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.
F. G. Clark, F. C. Hanker, W. H. Powell, I. R. Edmands, L. E. Imlay, W. R. Whitney, James J. Farley, F. A. Lidbury.

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
H. D. Arnold, J. C. Clark, Chester W. Rice, E. F. Burton, C. P. Eldred, Harold B. Smith, L. W. Chubb, C. L. Fortescue, H. S. Vassar, E. P. Hyde,

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman 2003 Farmers Bank Bldg., Pittsburgh, Pa.
P. H. Adams, W. C. Kalb, R. H. McLain, H. W. Cope, C. W. Kincaid, T. E. Penard, W. E. Date, A. C. Lanier, H. P. Reed, H. D. James, J. F. Lincoln, H. Weichsel, Fraser Jeffrey, M. J. McHenry, W. C. Yates.

INSTRUMENTS AND MEASUREMENTS COMMITTEE

F. V. Magalhaes, Chairman, 55 Duane St., New York, N. Y.
C. W. Baker, H. B. Brooks, G. A. Sawin, P. A. Borden, F. P. Cox, C. H. Sharp, Wm. M. Bradshaw, A. L. Ellis, H. S. Vassar. F. F. Fowle,

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Bldg., Philadelphia, Pa.
F. R. Crosby, R. B. Gerhardt, Wm. T. Snyder, F. D. Egan, E. S. Jefferies, G. E. Stoltz, Gordon Fox, Fraser Jeffrey, Wilfred Sykes, Eugene Friedlaender, D. M. Petty, F. H. Woodhull.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.
A. H. Babcock, W. T. Dempsey, W. D'A. Ryan, G. N. Chamberlin, J. F. Lincoln, B. E. Shackelford, A. B. Cooper, R. C. Powell, W. M. Skiff, James R. Cravath, G. H. Stickney

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.
J. B. Bassett, H. Franklin Harvey, Jr., G. A. Pierce, R. A. Beekman, H. L. Hibbard, L. B. Sinclair, Eskil Berg, W. F. James, H. M. Southgate, A. R. Cheyney, C. A. Jones, W. E. Thau, Maxwell W. Day, C. S. McDowell, F. P. Townsend, David D. Faris, W. F. Meschenmoser, A. E. Waller, E. G. Gallagher, I. H. Osborne, F. W. Wood.

MINES

Graham Bright, Chairman, W. E. & M. Co., E. Pittsburgh, Pa.
Willard C. Adams, L. C. Ilsley, J. F. Lincoln, R. T. Andrae, G. M. Kennedy, W. F. Schwedes, M. C. Benedict, R. L. Kingsland, F. L. Stone, W. A. Chandler, A. B. Kiser, C. D. Woodward. M. J. Lide,

POWER STATIONS

H. P. Liversidge, Chairman, Philadelphia Electric Co., Philadelphia, Pa.
J. H. Anderton, D. H. Braymer, F. D. Newbury, H. A. Barre, H. W. Eales, J. D. Ross, J. T. Barron, W. H. Lawrence, R. F. Schuchardt, A. E. Bauhan, I. E. Moultrop, H. R. Summerhayes, E. T. Brandon, R. B. Williamson.

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 W. Adams St., Chicago, Ill.
G. H. Bragg, H. W. Eales, A. A. Meyer, P. H. Chase, S. E. M. Henderson, N. L. Pollard, W. H. Cole, E. M. Hewlett, F. E. Ricketts, E. E. F. Creighton, F. L. Hunt, E. R. Stauffacher, L. N. Crichton, L. E. Imlay, J. W. Upp, W. A. Curry, J. B. Mac Neill, H. R. Woodrow. John C. Martin

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 132 Union Road, Roselle Park, N. J.
O. B. Blackwell, H. Hulatt, Stanley Rhoads, Jr., R. E. Chetwood, S. M. Kintner, S. A. Rhodes, E. H. Colpitts, L. F. Morehouse, A. E. Silver, A. W. Copley, J. P. O'Donohue, A. B. Smith, C. E. Davies, W. O. Pennell, W. K. Vanderpoel, H. W. Drake, L. M. Potts, F. A. Wolff.

TRACTION AND TRANSPORTATION

Charles S. Ruffner, Chairman, Adirondack Pr. & Lt. Corp, Amsterdam, N. Y.
A. H. Babcock, E. B. Katté, N. W. Storer, Reinier Beeuwkes, John Murphy, R. W. Stovel, R. H. Dalgleish, W. B. Potter, H. M. Warren, W. G. Gordon, R. H. Rice, F. E. Wynne. G. A. Richardson.

TRANSMISSION AND DISTRIBUTION

E. B. Meyer, Chairman, Public Service Electric Co., Newark, N. J.
R. W. Atkinson, J. A. Koontz, Jr., D. W. Roper, W. S. Clark, John Morse, R. F. Schuchardt, W. H. Cole, A. M. Perry, A. E. Silver, H. C. Don Carlos, C. N. Rakestraw, W. K. Vanderpoel, F. M. Farmer, F. E. Ricketts, C. E. Waddell, L. E. Imlay, C. T. Wilkinson.

A. I. E. E. REPRESENTATIVES

ON AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, COUNCIL

H. H. Humphrey, John B. Taylor.

ON AMERICAN BUREAU OF WELDING

W. L. Merrill.

ON AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, N. A. Carle, F. N. Waterman.

ON AMERICAN ENGINEERING COUNCIL OF THE FEDERATED AMERICAN ENGINEERING SOCIETIES

Comfort A. Adams, W. A. Layman, Charles S. Ruffner, A. W. Berresford, *William McClellan, *Charles F. Scott, *H. W. Buck, L. F. Morehouse, *L. B. Stillwell, F. L. Hutchinson, L. T. Robinson, *Calvert Townley
*Members of Executive Board.

ON AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart, C. E. Skinner. L. T. Robinson (Alternate)

ON BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY

H. H. Barnes, Jr., Bancroft Gherardi, H. A. Lardner

ON ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

ON FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt, L. B. Stillwell.

ON JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, Calvert Townley. E. W. Rice, Jr.,

ON JOINT COMMITTEE ON ENGINEERING EDUCATION

Charles F. Scott, (Vacancy)

ON JOINT COMMITTEE ON STANDARD THREAD FOR INSULATORS AND INSULATORS PINS

J. T. Barron.

ON LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle, E. B. Craft, W. I. Slichter

ON NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

ON NATIONAL JOINT COMMITTEE ON OVERHEAD AND UNDERGROUND LINE CONSTRUCTION.

Farley Osgood, Percy H. Thomas.

ON NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

ON NAVAL CONSULTING BOARD

Benjamin G. Lamme, Frank J. Sprague.

ON SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

F. C. Holtz, F. Conrad, Farley Osgood. W. H. Pratt, A. E. Kennelly, F. B. Silsbee S. G. Rhodes,

ON U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

WASHINGTON AWARD, COMMISSION OF

John Price Jackson, Charles F. Scott.

JOURNAL
OF THE
AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

Vol. XL | JULY, 1921 | Number 7

Personal Observations in the Industry

President's Address*

BY ARTHUR W. BERRESFORD

IF, in the selection of a subject upon which to address you, I have gone further afield than the profession of electrical engineering, or, indeed, have seemed to go even beyond the domain of the engineer, I trust that you will not lose sight of the fact that whatever benefits industry as a whole benefits the engineer; and again, if I seem to doubt the possibility of the engineer being competent in himself to solve all of the problems of our complicated civilization, I trust you will not consider me as holding him to be without function.

It is true that I am not in entire sympathy with what appears to be a growing feeling that the engineer may, with advantage, invade all fields of effort, and I think I perceive a growing resentment toward this conception of the engineer's function. I am not at all certain that the engineer should presume to advise in the relation between employer and employe, nor that he should consider himself competent to adjust the many problems which arise in commerce and industry. Is it not possible that the qualifications of the engineer have been confused with the methods of the engineer, and may it not be possible that what is desired is the application of engineering methods rather than the engineer in person?

However, this divergence in viewpoint might be reconciled—if there be not too much of heresy in the suggestion—by assigning the title of "engineer" (although of a class not yet provided with a distinguishing descriptive adjective) to those who are doing creative work in industry and commerce based on the application of these same engineering methods. If this lack of heresy be conceded, then is what I have to say proper for your consideration.

The outstanding characteristic of the present-day civilization is organization—the almost involuntary gathering together in groups of those possessed of interests in common; usually, in the beginning, that there may be facilities for the interchange of views on matters which engage the daily thought. This is the stated object of our own organization. Sooner or later, however, the possibility of other activities becomes evident and inevitably the initial purpose of the association is broadened and work is undertaken which results in common good. In the measure in which the purpose is altruistic and the element of self-interest is lacking, or enlightened, the accomplishment benefits not only the actual members, but industry as a whole, the community and the nation, and ultimately the world in which we live.

From the instinctive nature of their conception, these associations, however well-conceived for their specific purpose, will not be formed in accordance with some well-considered and throughly-planned scheme, resulting in a properly rounded and carefully calculated whole, but, on the contrary, will present to a broad view the impression of a series of unrelated bodies, each going forward in its own way, and, to an extent, ignoring the interests they have in common, until consideration is forced by some duplication of effort or conflicting action.

This condition has long been recognized and was under discussion when I became connected with the Institute as an associate member some twenty-five years ago. The thought then was that the Institute should be the dominant body in the industry, embracing all branches of activity and permitting the concentration of all available knowledge and experience on any given problem. The possibility of such an organization, or at least of a council, in which all might be represented, is still under discussion. Progress, however, has been along other lines, and today the probabilities are that such an organization would fall because of its very breadth and its consequent inability to deal with other than the broadest problems susceptible only of the most general of solutions. There would not be the concentration of interest necessary to the accomplishment of tangible results.

The major problem of the present day is the education of the mass of the people to the perception of true values. Most of our difficulties result from the honest misunderstandings of honest men—misunderstanding of speech, act or motive—with consequent growth of suspicion and inability to evaluate

Delivered at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

the opposing viewpoint. This is true of the employer-employe relation. It is equally true of the competitive relation. It is no less true of the relation of industry and government. If the condition is to be removed and the interest of our whole people advanced, the only certain procedure is through adequate education. In the employer-employe relation this can be carried on most effectively in the ultimate unit, namely, in the individual plant, and by those directly interested. In the industry it can be accomplished only through the understanding that comes from contact and interchange—as between industry and government only by the presentation of mass view of the industry, setting forth adequately, accurately and honestly the general need of all.

In other than matters of direct interest, such as the employer-employe relation, the association, for whatever purpose originally devised, forms the natural and obvious means of carrying forward this process of education so vital to our future. Men meet and weigh each other. Trust is born of knowledge and there follows the death of mistrust born of ignorance. Views are interchanged and opinions crystallize. Intelligent analysis determines the underlying fundamentals and does not mistake the symptom for the disease. The diagnosis properly completed, the remedy becomes apparent, and the policies based on the fundamental principles may be followed in the certainty that their consistent and persistent observation will ultimately produce the desired result, however long the interval.

But no single association can do this for an industry. It becomes necessary that all be represented. Particularly is this true in relation with government and governmental functions. No single group—whether corporate or associate—may assume to present the interest of the whole without arousing the suspicion that self-interest is present, as at least a considerable motive. Nor can it hope to be continually successful in this procedure, however much it may appear to accomplish initially.

These statements are so obvious as to appear trite, but how frequently one hears it said that the association operates mainly to the advantage of the minor interests; that the large corporation, complete in itself is self-sufficing; that it could and does perform for itself all that may be possible through association, and that in consequence it contributes to association by far more than it receives. The essential lack of soundness in this view is immediately apparent, however, when one considers the entire industry and the relation thereto of the large corporation.

For the proper development and economical operation of any industry, the major interests in that industry must have the understanding, support and good-will of those less important. This is true in direct ratio as the policies of these major interests are enlightened, broad and far-sighted. The human instinct of caution, emanating from centuries of need for self-protection, breeds both suspicion and jealousy of power. The policies of a minor manufacturer may be directly contrary to the interests of an industry as a whole, not by intent, but by reason of a limited point of view. He would be entirely willing to reverse these if there were clearly set before him the certainty of ultimate unfortunate result to himself as well as to others, but without this understanding any instance of interfering procedure by a major interest is certain to be interpreted as an assault upon his business for competitive reasons. He will, moreover, ascribe the success of such procedures to a wrongly held and unfairly exerted power by the large corporation rather than to its true cause, and he will be sincere in this attitude. The result must be an increase of suspicion, based on misunderstanding; of jealousy and resentment, based on a sense of personal injury; of mistrust, based on fear of future repetition. All of these breed waste and destructive competition, increase the ultimate cost and reduce distribution, with consequent injury to the industry as a whole and to the individual units which compose it—whether large or small.

If, on the contrary, the major interest, by contact and consideration, secures the trust and understanding of the smaller man, and if it proceeds still further and puts before him the facts and conditions which determine its policies, which data he has neither the facilities nor the opportunity to acquire for himself, thereby increasing his understanding and broadening his viewpoint, much that is otherwise impossible becomes practicable. It may be unfair that the larger interest should be called upon for the expenditure of time, money and patience necessary to this process of education and the devotion to it—as will initially be necessary—of their best minds, but their advantage is largely concerned and their ultimate success involved. The association provides the opportunity for this procedure.

From the industry's standpoint, therefore, the problem becomes the correlation of the necessary associations into a representative coordinating body and the direction of the combined effort in such manner as shall insure such advantage to its members as is consistent with the rights of others and the best interest of the public.

It is immediately evident, however, that the securing of this advantage to an industry—to the corresponding advantage of each division thereof including that of engineering—involves the correlation not merely of engineering associations, but of all associations interested—whether commercial, non-commercial scientific, or serving some special interest.

I sometimes feel that we of the non-commercial class hold ourselves too much aloof from those organizations whose function is apparently the promoting of the material advantage of their membership. There

may be, and is, as high an idealism in industry and commerce as in pursuits termed "non-commercial," and more than one operation of magnitude has been instituted and quietly carried through with far less of thought of ultimate profit than of the service to be rendered to humanity. We have every-day instance of something done for the general good and because it is right, that bespeaks a high-mindedness which those who pride themselves on freedom from commercial incentive may well admire.

And let us not forget that in the end the major incentive to result is self-interest and that properly educated and enlightened self-interest may accomplish more than a less practical altruism, and with no sacrifice of ideals.

Our portion of the work may be to increase the percentage of idealism, while at the same time encouraging the proper operation of this major incentive of self-interest which is absent from few or none; to direct it along broad and well-considered lines of principle and policy, with the elimination of opportunism, and to the end that each may strive to profit with the other, rather than at the expense of the other. There is nothing of communism in this. The reward of each will still be a function of his effort and ability, but there will come understanding of the reasons for the disparity in reward instead of revolt against a seeming unfairness; discontent with one's self and consequent increased effort, instead of jealousy and dissatisfaction with conditions; a coordinated working along well-defined lines, rather than individual attack at possible cross purposes, arising from restricted knowledge of the problem in its entirety. That such procedure must make for the maximum of progress in whatever line of activity it may be applied is self-evident.

Our own branch of industry is peculiar in possessing all of the elements present in any other and many in addition—all of the problems of manufacture and construction, together with specific problems demanding knowledge of almost every other branch in order that proper application of our product may be assured; an extended engineering content; a dependence on pure science and mathematics by far greater than any other of which I have knowledge and a more than ordinary interest in government relation—national, state and local—by reason of public service content. What other branch of industry involves so many factors? It would seem, therefore, that could we offer a solution for some of our own major problems, we would be pointing the way for all industry and that we might anticipate its concurrence and support in what we may initiate.

I have said that the major problem of the day is education, the major phenomenon organization, and that within the industry, organization—properly correlated—furnishes the obvious medium for the process of education; the question being to secure such correlation.

I believe this correlation could be attained if the broad fundamental principles underlying the industry could be enunciated, and if there could be developed therefrom the operating policies which the industry should follow. The proper and adequate performance of this task would secure the assent of all elements, and while permitting each organization to preserve its individuality unchanged would direct procedure along parallel lines leading toward the common goal. The points of common interest would be quickly and conspicuously developed and cooperative, harmonious relations thereon instinctively established.

Who is most competent to perform this task? It seems to me that there will be required the best minds of the industry—the men of the broadest viewpoint and experience and of the widest contact with all of the phases of our work. Where shall we look for such men? It is my opinion that they will be found in the executive personnel of our great corporations. The constructive ability, knowledge and grasp of affairs, keen perception of values and idealism which have put these men in these positions, and without which there could have been no such accomplishment, must result in their becoming the leaders, and, in the main, the doers of this work. That they could in no way more surely serve their own interests is beside the point. If they undertake it, they will do so from the broader viewpoint of rendering that service to their fellows for which they are the best qualified. That they will undertake it, I believe.

Assuming such a correlation, let us develop one or two of the problems which confront our own industry, and, in varying degree, other industries, and apply the factors which we have been considering. The appreciation of the ultimate dependence of industry on science and the consequent vital importance of research is of too recent birth to have attained general realization. The statement is accepted as a matter of course, but it has not come to be an actual, living, daily reality in the minds and life of most of us. That it will ultimately be so recognized is certain, and possibly in the near future. This being the case, how are we providing for it? The larger corporations are maintaining research laboratories—have been forced to do so by the demands of the industry—in which the bulk of this work has been directed toward the solution of specific problems, the results of which are generally conceived to be for the benefit of the corporation individually, and in part may be so initially.

The universities are carrying on research work in their laboratories to an extent determined by their financial resources and the initiative of their personnel; mostly of abstract nature, directed to the solution of general problems, chosen largely, and sometimes I think mistakenly, for the absence of applicational content.

The Bureau of Standards, under government auspices, and in the interest of the country's industry, is performing work of both types.

There are certain privately operated laboratories whose services may be employed by the industry in general for the solution of specific problems.

To determine how the work as a whole should be correlated to secure the maximum progress requires an understanding of the conditions.

The first conception which it seems necessary to establish is that all research is in the public interest—whether applied or abstract, and irrespective of whether its immediate object is the specific advantage of the concern or person undertaking it, or simply the increasing of the sum of human knowledge.

No one will question that abstract research, forming, as it frequently does, the foundation of important industrial advance, and given to the world without restriction, is definitely in the public interest. There may be those who question the content of what may be termed "practical applications" and who would limit investigation to the more promising possibilities, but the past gives ample warrant for future expectation, and no man can say in advance where value may be found. Much that today seems of no practical value may simply be awaiting the key discovery which will be found by no process other than that of this constant search for fundamental truth.

The misunderstanding seems to lie in the so-called "applied or applicational research," usually directed toward a specific problem, the solution of which becomes, under our patent system, the exclusive property of the instigator and a consequent source of gain. Is not this as it should be? Without this incentive no corporation could justify to its stockholders the necessary expenditure, and but few individuals would possess the necessary resources; for not every problem is solved and many months are spent in work that brings no fruition. Moreover, the period of exclusive use is limited and but short compared with the time during which the solution may ultimately be freely used by all. Again, the public as a whole usually reaps the benefit of the solution during this period of exclusive use and is advantaged in such degree as to make the reward to the owner small in comparison. A corporation laboratory produces ductile tungsten. During the life of its monopoly its profits may be great, but they are insignificant compared to the millions that are saved to the many who employ it in the incandescent lamp during this period, which savings will continue in effect long after the period of exclusive use is past. An improvement in the art of speech transmission may result in increased gain to the corporation controlling it, but it decreases the cost of the telephone to the user (or increases his possibilities at a given cost) even while the patent monopoly continues, and thereafter for all time. This is true in some degree of every successful applicational research.

It becomes clear, therefore, that *all* research is in the public interest, and that from the public viewpoint the sole difference in desirability between abstract and applied research is one of degree and not of fact; that the important point is increased research activity irrespective of where or by what means it is carried on.

There are two prime incentives—direct gain and the search for truth—the first more immediately productive of usable results, but aiming at what may be termed the details—the second laying the broad foundation for the future. There is no middle ground. No one can say at what instant an abstract research may develop an important practical application, and *vice versa*. The division between the two fields is a sharply defined line, not a neutral territory. It is fixed purely by the motive which animates the work. It is all of equal importance to the public and to the industry. It is comparatively unimportant how it is carried on and whether for a brief space someone shall be peculiarly advantaged.

In feeling that industry must supply the driving force, I am not setting the hope of gain as a greater impulse than the search for truth, but means must be supplied and to industry, the producer, we naturally turn. The hope of gain will impel the continuance of applied research where it is already established, and, where the individual concern cannot support its own adequate facilities, will widen the field by the institution of laboratories for the common use of groups possessing similar interests, once its value is appreciated. We may confidently expect, therefore, that this division of the field will show increased intensity of cultivation in direct ratio to the realization of its possibilities.

Fundamental research, however, must be provided for. The search for truth will supply the incentive, but not the means. Universities will do what their poverty permits, but it is not sufficient. Industry must increase the possibilities. An incentive must be offered to induce temperamentally fitted men to undertake this career and to become largely qualified, else industry will go begging for the men it will need in increasing quantity for its applied research. It may fairly be said that this condition is with us today, and that with the increasing demand there is danger that the universities will lose in practical totality those who must be depended upon to keep alive the spirit and train the men who are up-coming. Men now exist, in reasonable number, whose devotion and achievement in this field are an inspiration and an example for emulation among their co-workers which is of far-reaching effect. Given even a minimum of encouragement the future will continue to evolve them, and once in a generation or so a genius.

In the general consideration of such men in relation to organization, may I divert for the moment and offer a word of caution? Genius works not too well in harness and are there not already, both here and elsewhere, indications of a feeling that too much centralization and coordination may hamper or even cripple rather than facilitate?

I know of but one instance (there may be others) in

which industry has begun formal consideration of its relation to research in the universities. In February, 1919, the Michigan Manufacturers Association brought to the attention of the regents of the University of Michigan the desirability of establishing closer relations between the university and the industries of the state, realizing that in so doing an appreciable degree of cooperation would be through channels of research. The Regents' Committee considered the matter and favorable action was taken in January, 1920. The first meeting of a combined committee was held on May 27, 1920, and that committee is busied with the many questions involved. Where state universities exist no action could be instituted which promises more of ultimate value to the community.

If, then, industry must take the initiative, if only in its own interest (although I believe the action will be on broader grounds once the condition is appreciated) can it again do better than to secure the concentration upon the problem of the best minds that it possesses and to determine what is to be the relation and what course to pursue? I conceive that those most competent to form such an opinion are those who have the broadest knowledge of our industry and the largest experience with the problems and advantage of research, and again I conceive these men to be the best minds in our major corporations, irrespective of position—whether commercial, engineering, or purely scientific.

Consider the governmental relation as existing between the industry and the Bureau of Standards, in whose operations, by reason of our diversification, we have more than ordinary interest. During the last few years, I have heard many expressions of dissatisfaction with certain Bureau actions and activities, and have heard various causes assigned, among which were the belief of an existing total misconception on the part of the Bureau of its proper relation to the public; a feeling that the Bureau construes its function to be that of protecting the public against some possible unfair act or aggression of the so-called corporate interests, and that in consequence there is being bred in its people an unjustifiable suspicion of, and antagonism to, those who are engaged in operations for profit, and a lack of recognition of the fact that they also are part—and a useful part—of that same public; that this misconception, together with a seeming need for the initiation of activities which should directly appeal to the popular mind in order that appropriation committees might be impressed, are carrying the Bureau beyond its proper scope and into fields of work for which it is ill-fitted—which fields could be covered to far greater advantage by other agencies and methods—and that in consequence distinct damage is being done. Doubt is even expressed of the actual desirability of the Bureau.

These are formidable allegations and must have their foundation in some measure of truth or in misunderstanding. In any event, they are serious and if either the conditions or the misunderstandings are not eliminated, definite harm will result.

The conception of the elimination of the Bureau is surely exaggerated. It requires but little consideration to determine that the maintenance by the government, and under conditions beyond suspicion of improper influence, of a central authority, dealing at least with weights and measures, is essential. That the scope of such an activity may well be extended beyond so limited a function seems equally evident. My own conception is that it may helpfully be broadened to the determination and establishment of all matters of physical fact, but that it should stop short of matters of opinion or economics, but I may be too conservative. The obvious condition is that divergence of opinion exists, and that there will be increasing lack of harmony unless this divergence is removed.

The Bureau has undoubtedly devoted much thought to the course it has adopted. How much real consideration has the industry given to the subject? Is not the situation an instance of two groups, each proceeding along its own preconceived line, until the attention of each is concentrated on the other by an apparent conflict of interest? If the scope of the Bureau's work is of direct interest to the industry—and it seems to me to be of vital interest—then is the situation sufficiently serious to demand the most careful consideration of the industry—and sufficiently acute to demand it immediately.

As to the personnel of the Bureau, I know of no more unselfish, self-sacrificing, patriotic body of men. I have yet to meet one who has given his personal interest even the consideration it merits. If these men are not proceeding along the most helpful lines, it is because of a mistaken conception of what is their duty. Whatever they are doing, they are doing honestly, and there is always a complete willingness to discuss freely and fairly any objection which may be urged. If such misconceptions exist, how much has the industry done to correct them? These men are not of commercial type, nor are they in touch with affairs. How is it to be assumed that they will, out of pure instinct, foresee all of the effects on our complicated industrial structure of some activity undertaken by them in all honesty and apparently in the interest of all? To what extent has industry striven to make clear its condition, instruct the Bureau in its problems and convince the Bureau of its good faith? Is there any other method of curing whatever undesirable condition may exist in this respect?

Again, if there actually exist conditions which have induced what industry may consider as an undue expansion of the Bureau's field in order that the importance of the Bureau may be enhanced in the minds of members of Congressional Appropriations Committees,

then is not the industry to blame for these conditions? If, in the interest of the farmer, it is deemed necessary and desirable that millions be spent in agricultural research—and not only public opinion, but the results of record affirm the wisdom of this expenditure—is it not incumbent on industry similarly to make clear to the government its needs and demonstrate to it and to the public the importance and necessity of meeting them? The amount required is far less than the expenditure for agricultural research and the value of the products affected is of at least the same order. Is it consonant with the dignity of the Bureau and the men who give their lives to its work that they should be obliged to manoeuvre for the necessary support, and that when given, it is so meagre that the work is hampered and the men themselves so poorly compensated that many, contrary to their own desire, but purely that their families may live in reasonable comfort, have been obliged to terminate their career of public service and take up more gainful occupation? I conceive it to be the prime duty of the industry, first, to agree on what shall be the scope of the Bureau; second, to educate the Bureau in its conditions; and, third, by demanding that its interests be heeded, to secure the adequate support of the Bureau.

Only a united industry—commercial and non-commercial—can do this. The electrical industry, by reason of its greater interests, should initiate it and carry forward, through its associations, the necessary process of education; and, again, I believe that these same leaders of the industry are most competent to determine the fundamentals and the policies by which we should be guided.

My conception, then, is that the immediate need of the industry is the enunciation of what are its fundamental principles, the statement of what should be its working policies and the outlining of what should be its relation to the major problems which confront it; that there is a sufficiency of organization and of interrelation of organization; that there should be added only cooperation for specific objects where progress or legitimate interest directly indicates its desirability; that the matters in which this cooperation may be applied and the agencies between which it is necessary will be made evident only by the broad analysis suggested; that once made evident it will be instinctive, effective and efficient.

There may be disagreement with my feeling that this analysis would best be made by men in the corporate relation and the thought may be that it would better be done by conference of the industry's organizations, since if this procedure were followed any suspicion of an undue degree of self-interest would be eliminated; but I ask consideration of how cumbersome would be the procedure and how small the probability of reasonable expedition in reaching results. The mere fact that numbers of men would be engaged instead of four or five would make for extended deliberation, and time is an essential element. Moreover, it is evident that the prononucement, when made, would be accepted by the industry only in the degree that it embodies the breadth of view and the knowledge which these men possess and the honesty of purpose which I am certain they would bring to the task. My belief is that it would be thoroughly acceptable. It is no small service to ask of them, but again I am confident that it will be rendered willingly if the industry realizes its importance, agrees as to the method and makes the request.

STANDARDIZATION OF ENGINEERING PRODUCTS

A conference, unofficial in character, of the secretaries of the various standardizing organizations at present in existence was recently held in London. The conference was opened by the chairman of the British Engineering Standards Association, Sir Archibald Denny, Bart. The following secretaries were present:—Dr. P. G. Agnew, U. S. A.; Mr. A. Erikson, Norway; Mr. E. Hijmans, Holland; Mr. J. R. Durley, Canada; M. G. Gerard, Belgium; M. Zollinger, Switzerland; and Mr. C. le Maistre, C. B. E., Great Britain. The object of the conference was the exchange of ideas tending towards the establishment of closer relationship, and from that point of view it was eminently successful. Each secretary gave a brief report of the general organization of the work in his country and the methods adopted in arriving at the standards, as well as the principles followed to ensure their adoption when issued. * * *

Some enthusiasts are rather apt to think that the time has arrived to attempt to create an international organization for standardizing all engineering products; but the conference, it is understood, took a much more modest view and, seeing the almost insuperable difficulties in the way, preferred to see international standardization develop along national lines and sectionally, similar to those adopted, for instance, by the electrical industry in the case of the now well established International Electrotechnical Commission. The Conference having no executive functions whatever, each secretary will in due course submit to his respective organization the suggestions of the conference on the various points discussed.

The secretaries were entertained by the British Engineering Standards Association during their four days' conference. The human factor enters so largely into all questions of standardization that the meeting of the secretaries of these important bodies, * * * is bound to be of no small advantage in the future and materially assist in guiding international intercourse on this complex question along right lines. —*The Engineer*, London.

Hydroelectric Development at Niagara Falls

BY JOHN L. HARPER and J. A. JOHNSON

Both of The Niagara Falls Power Company

THE PURPOSE of this paper is to trace briefly the progress in the art of power development at Niagara Falls from its beginning to the present time, to describe more particularly the recent developments and those about to be undertaken under the recent license granted to The Niagara Falls Power Company by the Federal Power Commission, and to indicate the present and probable future functioning of Niagara power in the industrial development of the country.

The physical conditions existing at Niagara Falls are not duplicated elsewhere in the world. The immense drainage basin of the Great Lakes contributes an almost uniform outflow of water of such magnitude that the question of adequate supply is not one which need be considered for many years to come. This continuous flow of over 200,000 cu. ft. per second, finds its outlet through the Niagara River which falls through a total height of 336 ft. between the Lakes Erie and Ontario. Of this 336 ft., 165 ft. is concentrated in the cataract itself and another 55 ft. is in the rapids immediately above, so that within a distance of one mile there is available a total head of 220 ft.; or, combining the 94 ft. of drop in the lower Rapids with that above, there exists a head of 314 ft. which may be developed within about five miles, distances being measured on the American side of the river. This flow of water and the natural head available provide a source of power of over 6,000,000 h. p. which, under ordinary conditions, one might expect would be used to the full for industrial purposes.

One factor alone has prevented the perfect working of economic law in this respect, and that factor is the value of the cataract and rapids from the scenic standpoint. That this value is a real one, no thoughtful person will deny. "Man cannot live by bread alone," and who can doubt that God who, in His infinite wisdom, gave us Niagara, intended it to minister to the spirit as well as to the body of mankind.

This division of Niagara's ministration between the material and the spiritual, has always existed since Niagara became known to civilized man, but it is just beginning to be recognized that the division must ultimately be made at that point where the sum total of human benefit shall be a maximum. And when that point is finally determined, the portion of the energy which is found not necessary to maintain the spiritual values will undoubtedly be made available for industrial purposes.

As early as 1725, nearly 200 years ago, a primitive sawmill made first use of Niagara power, and 100 years ago small waterwheels were used in mills located along the upper rapids on the shore and small islands of the American channel; but these early developments have long since disappeared and very little evidence remains to show that they once existed. A short piece of the original headrace is now converted into a scenic pool just upstream from the Goat Island bridge, and the size and nature of these mills is indicated by the accompanying illustration (Fig. 1).

The beginning of the existing power developments may be placed as far back as 1852, when the construction of a hydraulic canal was begun, extending from a point at the head of the rapids above the falls, now known as Port Day, to the edge of the gorge a mile below. In spite of the fact that the land for the right of way had been donated by the Porter family who then owned most of the land bordering the Falls, lack of funds caused a suspension of the work in less than two years. However, it was resumed in 1859, and by 1861 there was completed a canal from 20 feet to 36 feet wide and about 8 feet deep, extending from Port Day to the present canal basin at the edge of the gorge in the same location as the present Hydraulic Canal of The Niagara Falls Power Company.

FIG. 1—VIEW FROM GOAT ISLAND

Looking toward the American shore before the establishment of the Niagara Reservation, July 15, 1885, showing paper mill on Bath, now Green Island

Owing to the industrial depression caused by the Civil War no use was made of this early canal for years although a small stream poured over the cliff unused.

In 1872, however, an installation of 150 h. p. under 25-ft. head was made for driving a grist mill. In 1877 the canal property was purchased by Jacob F. Schoellkopf and others who organized, in 1878, the Niagara Falls Hydraulic Power and Manufacturing Company. Soon afterwards the Schoellkopf-Mathews flour mill was constructed and equipped with 900 h. p. undes 50-ft. head. Four years later the head on the mill wat increased to 86 ft. which at that time was the highest

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

head used at Niagara. Quite recently some sections of the iron flumes, 9 ft. in diameter, which were the first iron penstocks used at Niagara Falls, have been removed to make room for the works in the latest development.

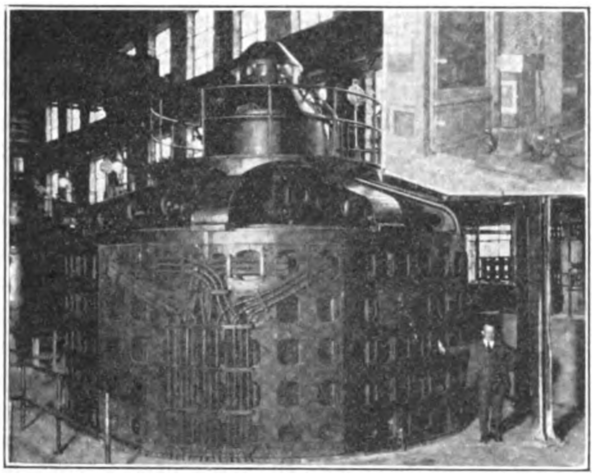

Fig. 2—Earliest and Latest Commercial Generators to Operate by Niagara Power

From this time on the Hydraulic Canal was used for supplying water power for manufacturing in important mills. The general method of development was to sink shafts or pits under the mills at the edge of the cliff, taking the water from the canal through flumes and penstocks to turbines at the bottom of the pits

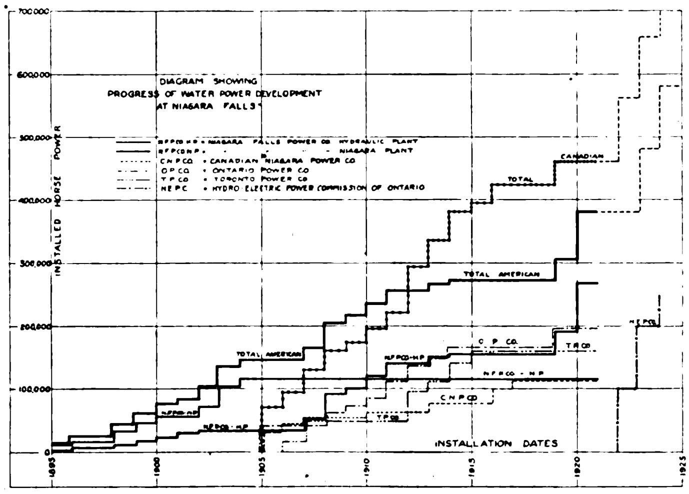

Fig. 3

and allowing it to discharge from short tailrace tunnels part way down the face of the cliff. The waterwheels were directly connected to vertical shafts which drove the machinery in the mill above.

In the year 1880 the first hydroelectric unit was installed at Niagara Falls, in Prospect Park. This unit, comprising a waterwheel and a d-c. brush dynamo, was used for illuminating fountains in the park by means of two arc lights. Excursions were run from various parts of the country to see the new wonder. This unit has little more than historical interest and diligent search has failed to reveal any photograph of the installation or any technical data concerning it.

The second hydroelectric development and first commercial installation was made in the year 1885 in

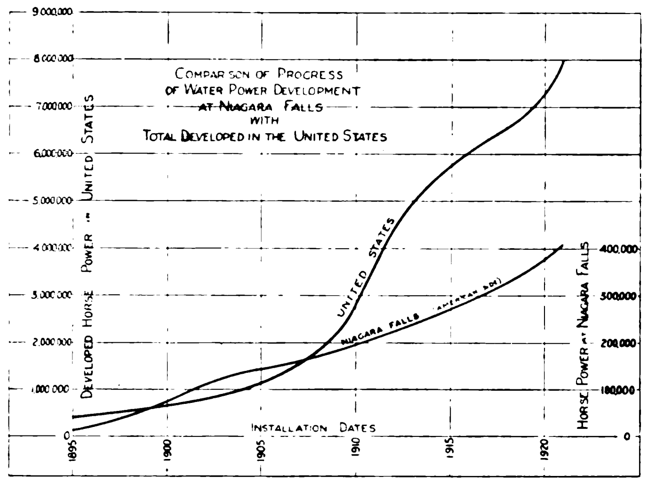

Fig. 4

the Pettebone Mill on Bath Island. The generator of this unit, which was used for lighting the mill, is shown in the insert in Fig. 2. It was a d-c. machine, having a capacity of 16 amperes at 110 volts. It is interesting to note that the capacity of the latest generator operating at Niagara Falls is about 15,000 times as great as this one. The contrast is shown in the illustration.

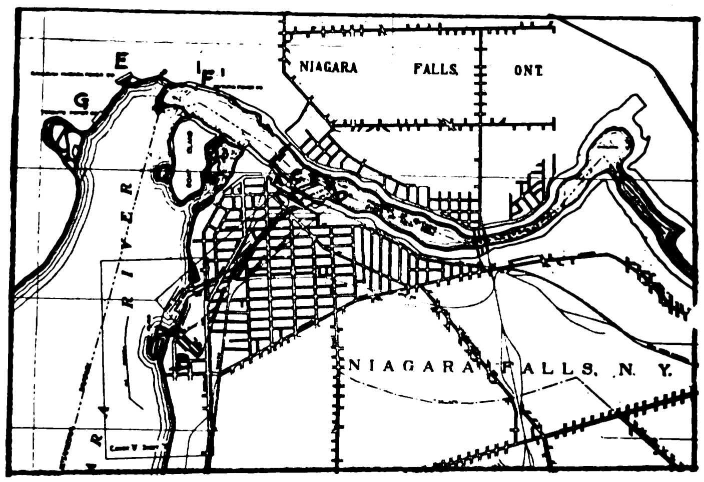

Fig. 5

As soon as these early installations had demonstrated the possibilities of electrical power, the real hydroelectric development began, and in the year 1891 The Niagara Falls Hydraulic Power and Manufacturing Company began the construction of its Station No. 1, in which dynamos were installed, operated by rope drives from waterwheels and having a total output of 2000 h. p. which was used for supply-

ing electrical power for commercial purposes. This station was abandoned in the year 1904.

In 1886, or about the time the second hydroelectric development referred to above was begun, The Niagara Falls Power Company was organized with the intention of developing hydraulic power only, the power to be delivered from the waterwheels direct to the shafting in the mills to be located along a head-race about a mile above the falls, and the tailwater to be collected in a low level tunnel draining into the lower gorge. Negotiations for the construction of the works were not completed until 1889, at which time it became clear that concurrently with the development of hydraulic power, the company could proceed with the development of electrical power and transmission. So successful was the early use of electrical power that a decision was reached in the year 1890 to install three hydroelectric units of large size, each having a capacity of 5000 h. p. A step-up transformer station and 11,000-volt transmission line to Tonawanda and Buffalo were also undertaken. Power from this station was delivered at Niagara Falls in the year 1895, and at Buffalo in 1896.

By this time the hydroelectric power development was fairly under way, and Fig. 3 shows the progress from then on up to the present time. Fig. 4 shows a comparison between the rate of progress in hydroelectric development at Niagara Falls and that in the United States as a whole. From this comparison it will be noted that progress at Niagara has not at all times kept pace with that of the country in general.

The period from 1895 to 1905 might be called the "Decade of Progress" in power development at Niagara Falls, when the various companies at work on the American and Canadian sides devoted themselves to overcoming many natural difficulties and to the building of what were then the largest plants in the world.

About 1905 the Niagara Falls Power Company had completed its American plant, marked *B* on Fig. 5. The Hydraulic Power and Manufacturing Company had abandoned its Station No. 1 and completed its Station No. 2, marked *A* and *C* respectively; and in addition other plants were well under way, namely Station No. 3 of the Hydraulic Power Company, marked *D*, and the three plants shown on the Canadian side marked *E*, *F* and *G* belonging respectively to the Canadian Niagara Power Company, the Ontario Power Company and the Toronto Power Company.

These plants have been described so often that no doubt they are quite familiar to all engineers and it will be unnecessary to refer to them in detail. It will be noted, however, that three different types of waterways were employed, *A*, *C* and *D* utilizing a surface canal, *B*, *E* and *G* wheel pits and tailrace tunnels, and *F* pressure pipe lines and open tailraces. The type of waterway determined to some extent the type of machinery; plants *A*, *C*, *D* and *F* being able to use horizontal shaft units with journal type bearings, and plants *B*, *E* and *G* being forced to adopt long vertical shafts with the then less desirable thrust bearings for supporting the weight of the revolving machinery.

In the year 1906 the Governments of the United States and Canada became alarmed at the rapid improvements in the art of power plant building by which the Falls of Niagara were being made to serve the needs of man and its consequent diversion of water from the cataract, and after due deliberation the Burton Bill and the International Waterways Treaty made it unlawful to divert more than a specified quantity of water for power purposes, namely 20,000 cu. ft. per sec. on the American side and 36,000 cu. ft. per sec. on the Canadian side. In this negative way it was hoped to save the great spectacle from destruction.

These laws cast a blight upon the development of the art at Niagara Falls and the period from 1906 to 1916 might properly be called the "Decade of Stag-

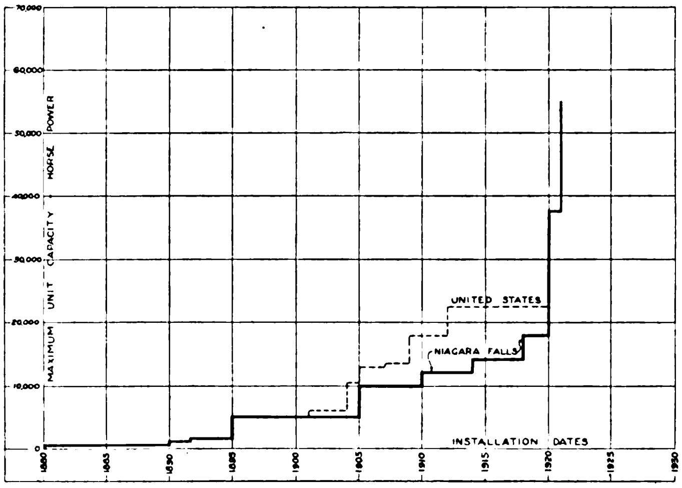

Fig. 6

nation." It is quite true that additional units were installed in the existing plants during this interval, but with no future to look forward to there was little incentive to improvement, and little attempt was made to keep pace with the advances being made in other parts of the world. The plants were completed for the most part in very much the same manner as they were begun in 1905.

As an indication of the foregoing, Fig. 6 shows how the development at Niagara Falls lagged behind the progress being made in other parts of the United States in regard to the size of units being constructed, until finally in 1918 Niagara Falls was restored in this respect to its rightful position of first place.

During this time Public Opinion in regard to Niagara Falls found expression along two diverging lines of thought, one claiming that diversion for power purposes would ruin the scenic grandeur of the falls and therefore should be stopped entirely, the other

representing those interested in the work at the falls, who insistently pointed out the folly of attempting to save the falls from destruction by allowing them to destroy themselves. As year after year went by it was apparent that 6 to 8 ft. of yearly erosion at the apex of the Horseshoe amounting to at least 60 ft. in ten years was doing more to draw the water from the sides of the Horseshoe and destroy its beauty than all

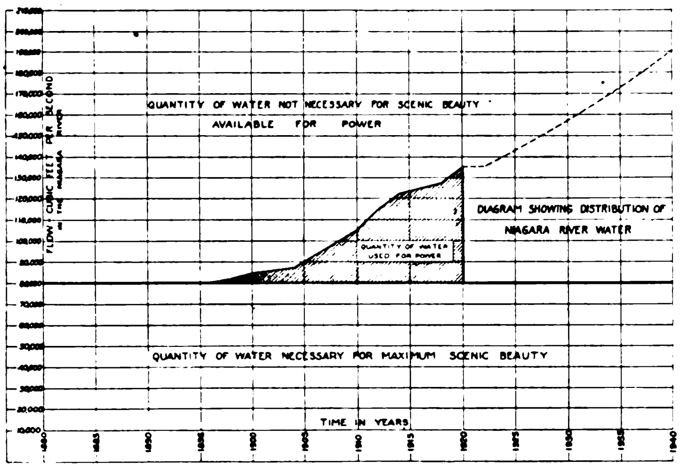

Fig. 7

the power plants put together. Once this fact was realized the remedy became self-evident. It is now recognized that by far the greater part of the water in the river not only contributes nothing toward the scenic grandeur but rather tends to detract from it by sending up clouds of spray to obscure the otherwise beautiful sight; and not only that, but is actually destroying the scene by erosion. Instead of arbitrarily restricting the amount of water which may be diverted for power purposes, the sensible thing to do is to adopt some measures that will spread so much of the water as is required for scenic beauty evenly over the crests of the falls and to divert all the rest for power purposes, thereby conserving for all time and to the greatest extent both the spiritual and the commercial values. This division of the flow for scenic and power purposes as recommended by Government engineers is shown in Fig. 7.

During the war emergency and at the suggestion of the representatives of the War Department, the Niagara Falls Power Company, Hydraulic Power Company of Niagara Falls and the Cliff Electrical Distributing Company were merged under the name of The Niagara Falls Power Company, but under the control and management of the owners of Hydraulic Power Comapny, the merged interests owning all the developments on the American side and controlling the Canadian Niagara Power Company on the Canadian side. These plants had a total installed capacity of 350,000 h. p.

Under this unity of control and direction, a plan was quickly evolved not only for immediately placing all developed power at the disposal of the Government agents for distribution to specified customers who were making the materials vital for war work, but also for the rush development of another 100,000 h. p. without sacrifice of permanency of work or efficiency of conversion. These construction plans were being rushed to completion when the signing of the armistice made speed less important; however, the whole 100,000 h. p. was put in operation within 22 months from the time they were authorized.

Shortly afterward, however, the Government of the United States established the new Federal Power Commission, one of whose first acts was to give approval to the plans being carried out by The Niagara Falls Power Company and to issue a license to the company for all the water permitted to be diverted from the American side of the falls in accordance with the terms of the existing treaty. At the same time it recommended an increase in the allowable diversion and the construction of remedial works to preserve the beauty and grandeur of both the American and Horseshoe Falls.

This license gave formal federal approval to the plans of development already begun, and authorized their completion. These plans include the placing in reserve of the present Niagara plant marked *B* on Fig. 5, the construction of a new waterway from Port Day to carry the water now being used in the Niagara Plant to the Canal Basin, the maintenance of Station No. 3, marked *D* on Fig. 5 with its 13 effi-

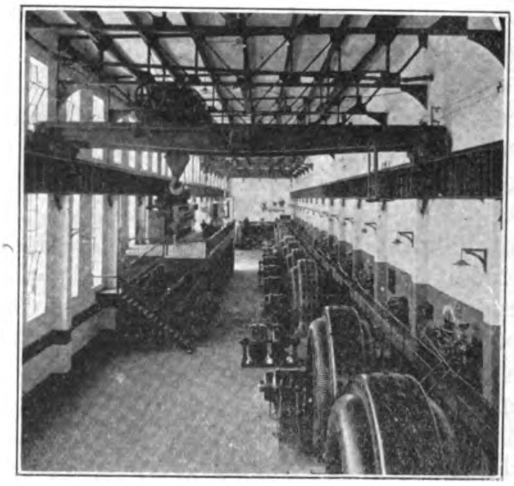

Fig. 8—Interior of Station No. 3 Generator Room

cient 10,000 h. p. units operating under a mean gross head of 217 ft. (see Fig. 8), the extension of this Station to the southward and the construction of new units to utilize the 4400 cu. ft. per sec. of water that had not been specifically allotted under the treaty and the water now being used by the Niagara plant. Plans were made so that subsequently the water used by these plants may be re-collected at the most favorable point and carried by tunnel past the lower rapids to a

power house in the lower river where the remaining head may be developed.

The first step of this general plan has already been carried out, namely the construction of what is known as Station No. 3 Extension, marked *H* on Fig. 5, begun in 1918 as a war measure and finished in 1920. This extension contains three units, the combined rating of which is 100,000 h. p., and, together with the other plants of the company, uses all the water allowed by the treaty. The second step has just been authorized, namely the construction of a new tunnel and the installation of the remaining units in an addition to Station No. 3 Extension, marked *K* on Fig. 5.

The third step also has been initiated by the granting of a preliminary permit to The Lower Niagara River Power and Water Supply Company, which allows two years for the presentation of plans for the second or lower river stage of the development. The details of this plan have not yet been worked out and the date of its contruction has not been finally decided upon.

Much has been said about the desirability of using the diverted water under the full head of 314 ft. from the upper river to Lewiston, and when the field is entirely without complication, as in the case of the development of water in excess of the present treaty allowance, a one-stage development will undoubtedly be advisable. The reason for the apparent rejection of this plan for the present diversion may be of interest. As a matter of fact, the scheme of development now being carried out does contemplate the use of the full 314-ft. head, but instead of utilizing this head in one plant with a long new waterway involving the abandonment of the efficient plants already built, it will be utilized in two successive stages, the first stage utilizing a gross head of 220 ft. and the second stage a gross head of 94 ft.

Broadly speaking, the commercial power capacity of the two-stage development is practically the same as that of the single stage, such slight theoretical differences as exist being in a practical sense unimportant. The problem then has been to decide whether the interests of the power consumers, and indirectly of the public, would be best served by an eventual total abandonment of all the plants that had already been built and the construction of a new plant to utilize in a single drop under the full 314 ft. head, the total quantity of water permitted to be diverted under the treaty, or, by conserving as much of the old work as could be conserved without impairing the general efficiency of the use of water and the construction of new works to supplement the old. It is an axiom that whether a power development is constructed with private or with public funds, the consumer pays the cost. A breach of economic laws, therefore, must be immediately reflected in increased rates. A careful study was accordingly made to determine the most economic development, particular attention being paid to the vital factor of interest on the investment during construction and on the unutilized portion of the new works during the period of business development, items which run into millions of dollars owing to the long time required to build and secure a market for these large developments. The general conclusions of this study are expressed in the plans above outlined.

The gradual advance in the efficiency of the Niagara power developments is shown in Fig. 9. This chart is very interesting. The left-hand end of the horizontal lines shown for each of the developments, indicates the earliest date at which the corresponding efficiency was obtained, and the smooth dotted curve made by joining these points is quite remarkable as showing the regular working out of the law of diminishing returns in the progress of these developments. The growth of efficiency, particularly as to those plants employing the headrace canal type of development, seems to have worked itself out according to quite

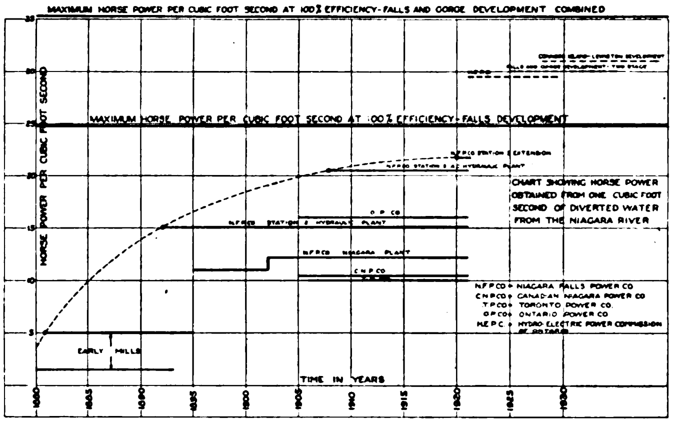

FIG. 9

a definite law and shows the inevitableness of the lack of efficiency of the earlier plants. This curve, provided that it holds for the future as for the past, also indicates the great unlikelihood of any considerable further gain in efficiency, and the probability of a very low rate of obsolescence for Station 3 and Station 3 Extension.

It will be observed that the rate of obsolescence of the earlier Niagara power developments was fairly high, decreasing however, for the later developments, as the art has progressed. The question then naturally arises as to what rate of obsolescence may be expected for this latest development. Obsolescence is undoubtedly a function of efficiency, defining that expression in terms of power and cost, and involves two factors, namely, general operating efficiency, which is promoted by the use of compact stations with large reliable units of similar characteristics; and efficiency in the use of water, which latter again involves first, the development of the maximum available head and second, careful design to get the maximum possible power out of the available water at the head developed.

These curves show very clearly how the develop-

ment of the art quickly ran through the early stages when only very small units were built, of diverse characteristics, and when only a small part of the available head was utilized, and how such plants rapidly became obsolete on account of the great gain to be obtained by building larger and better designed units under higher heads.

Analyzing this latest development in the light of these considerations we find, first, as to the efficient

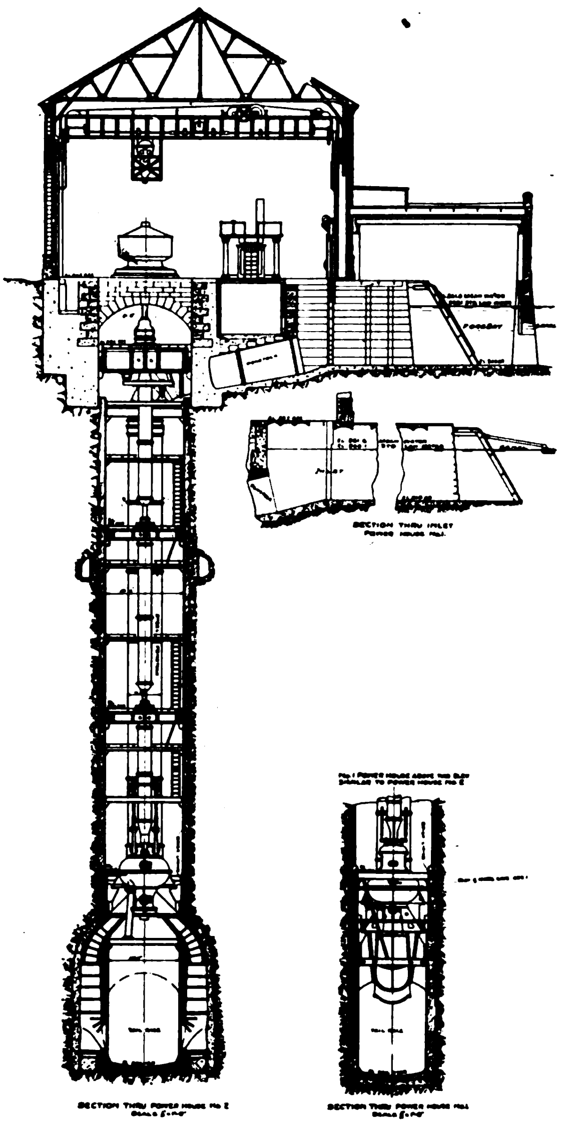

FIG. 10

use of the site, that the entire available 220 ft. has been developed with less than 2½ per cent loss in getting the water to the penstocks; second, that of the power available at the penstock entrances, over 91 per cent is delivered in the form of electrical power at the generator terminals; and finally, that although the size of future units may be increased, such increase of size being permissible when the system of which they are a part increases, there is relatively little more to be gained either in lessening cost or cheapened operation, the present 100,000-h. p. three-unit extension requiring but three men per shift to operate it.

These results are so far in advance of previous installations and leave so little room for improvement that is appears justifiable to say that obsolescence of

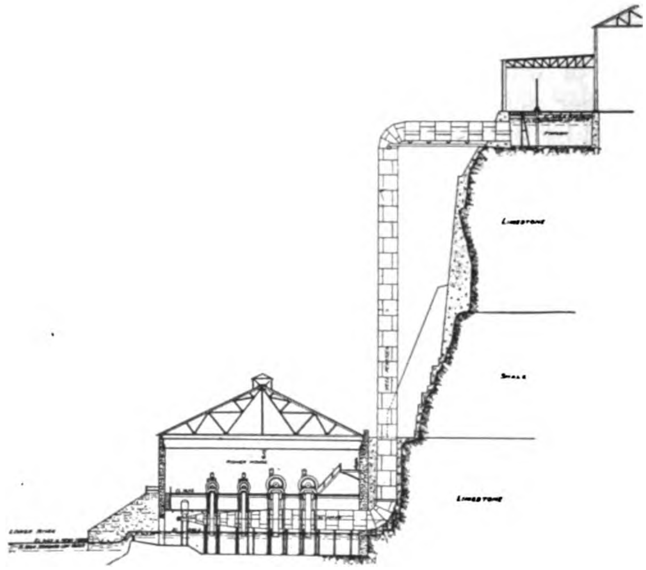

FIG. 11—CROSS-SECTION—STATION NO. 2

this plant could be brought about only by some scientific advance in the art of power production of a totally unexpected and revolutionary character.

The recent investigation and report on Niagara conditions by Col. J. G. Warren and its analysis by other federal engineers has supplied a long felt want of authentic data, and has answered with peculiarly

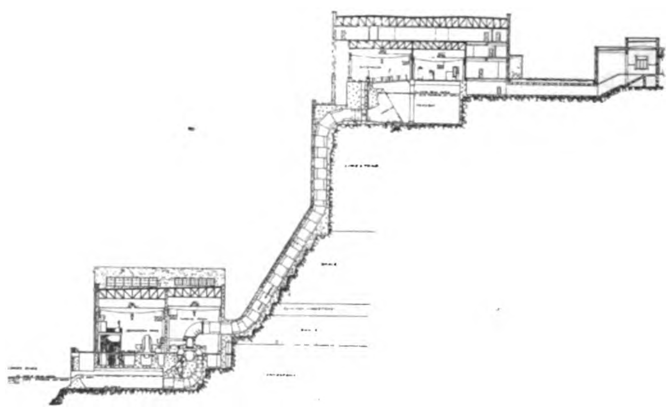

FIG. 12—CROSS-SECTION—STATION NO. 3

disinterested wisdom many of the hitherto perplexing questions in regard to comparison of plans for developments, and also as to the amounts of water necessary for maximum scenic grandeur and the amount that can be released for power purposes. This compilation of data and the well thought out conclusions therefrom, made it possible for the Federal Power Commission to come to a quick determination of the proper form of development to be adopted, which was expressed

in its first license which was issued to The Niagara Falls Power Company on March 2, 1921.

The nature of the developments made on the American side at Niagara, prior to 1918, are shown by Figs. 10, 11 and 12. Fig. 10 is a typical cross-section of the Niagara Plant (formerly The Niagara Falls Power Company) shown at *B* in Fig. 5. Fig. 11 is a cross-section of Hydraulic Plant, Station No. 2. Fig. 12 is a section of Hydraulic Plant, Station No. 3.

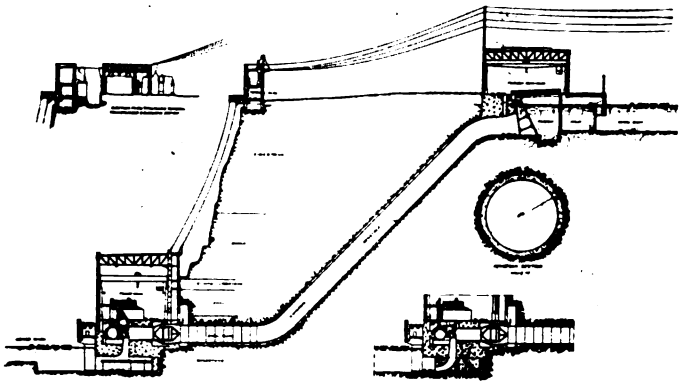

Fig. 13—Cross-Section—Station No. 3 Extension, Existing and Proposed

Latest Completed Development

The latest development known as "Hydraulic Plant, Station No. 3 Extension," which is the first section of the work authorized by the license from the Federal Power Commission, is shown in similar section in Fig. 13. The three plants shown in Figs. 11 to 13 are all located in the gorge on the bank of the lower river about half a mile below the falls as shown at *C*, *D* and *H* in Fig. 5. A plan view of Station No. 3 Extension, showing its relation to Station No. 3, is shown in Fig. 14.

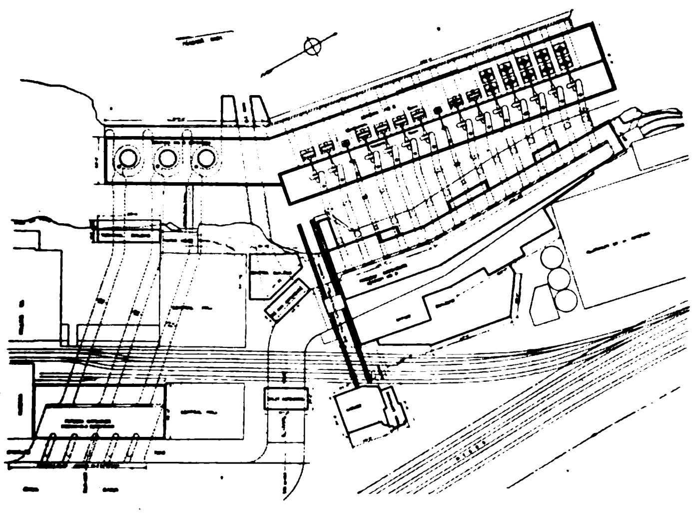

Fig. 14—Plan—Station No. 3 and Station No. 3 Extension

This development was designed to utilize the 4400 cu. ft. per sec. of water which was still available under the treaty. It consists of an extension to Station No. 3 containing three units of 37,500 h. p., maximum rating. To distribute this power it was necessary to construct a distributing station three miles away to which the power is transmitted from the generating plant by overhead lines.

In order to get the water out of the river and delivered to these units, it was necessary to make more adequate provision for ice protection at the intake at Port Day, which work is shown in plan in Fig. 15. These improvements comprise a channel dredged in the river bottom extending out into the river a distance of approximately 3000 ft. and a new ice deflecting boom crossing this channel near its outer end. By this means an adequate water passage is always assured even though the surface for many feet deep may be congested with ice floes. Since the completion of this work no trouble with ice has been experienced.

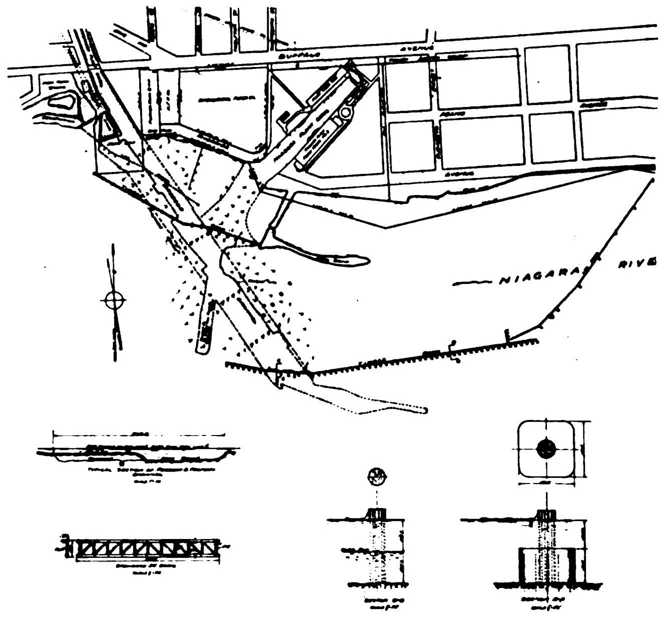

Fig. 15—Detail Map of Project Area

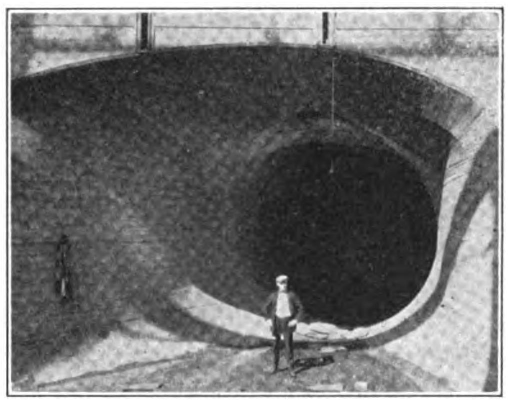

Fig. 16—Bell Mouth of One of the Penstocks

It was also necessary to deepen the Hydraulic Canal throughout its whole length to a depth of 20 ft., an increase of from 6 to 10 ft. over its former depth. This work was carried out under great diffi-

culties due to the rapid currents through the canal supplying the already existing plants.

Connected to the Canal and its terminal basin there was constructed a new forebay 176 ft. long, 74 ft. wide by 28 ft. deep. The entrances from this forebay to the three penstocks are bell mouths (Fig. 16), 28 ft. wide by 20 ft. high, and gradually taper down to true circles 15.5 ft. in diameter. The penstocks are

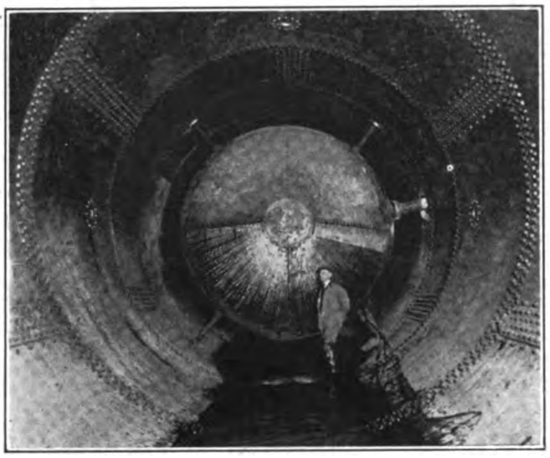

Fig. 17—Upstream End of Johnson Valve Inside of Penstock

350 ft. long, cut in solid rock, and are lined with concrete throughout their entire length. The horizontal section, in addition to having a concrete lining is also lined with boiler plate. The general arrangement is clearly indicated in the sectional view, Fig. 13.

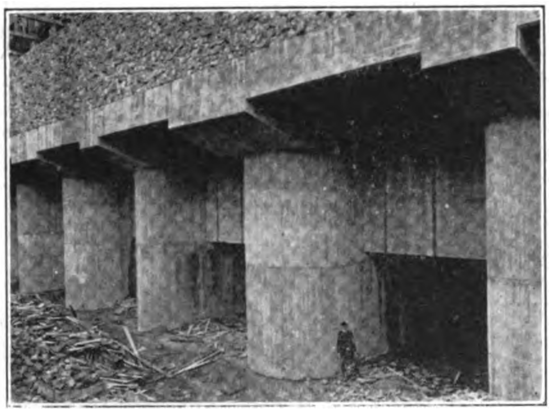

Fig. 18—Tailrace Discharge Openings through Power House Foundations Showing Concrete Supporting Piers

A plate-stee gate is provided for the intake to the penstock. This gate is only used when it is desired to unwater the penstock.

Each of the three turbine casings is connected to its penstock through a valve, (Fig. 17) hydraulically operated and electrically controlled.

The valves are of the balanced needle type, having a movable plunger sliding in an internal cylinder. Operation of the plunger is accomplished entirely by the hydraulic pressure in the penstock, no external force or pressure being required. The valve may be manually controlled locally, or electrically controlled from a switch station on a pedestal near the generating units. The rate of the valve stroke may be regulated to suit the conditions and may be set for any time up to a minimum of 30 seconds for a complete stroke in either direction. The valve is so designed that it will close automatically in case of a serious break in the wheel casing.

No provision was necessary to take care of the surges in the penstock, for being hewn through solid rock the penstock itself provides sufficient strength to withstand any force that may be set up, due to suddenly shutting down a machine.

In the design and building of the units four manufacturing companies are represented. Each turbine is of the vertical shaft, single runner, Francis type, operating under a head of 215 ft. at a speed of 150 rev.

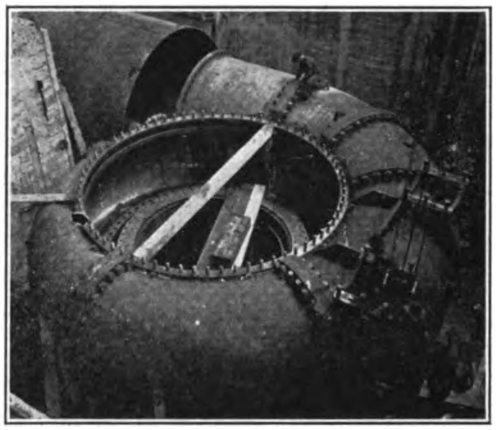

Fig. 19—One of the Cast Iron Turbine Cases

per min. and is rated at 37,500 h. p., although each has already carried more than 40,000-h. p. load. The three units were designed to develop an average working load of 100,000 h. p. Taking all frictional and other losses, from forebay to switchboard, into consideration, these units are securing over 91 per cent of the potential energy in the water used.

Each complete unit—generator, turbine and casing—weighs approximately 1000 tons and is set on a reinforced concrete slab, 11 ft. thick, 53 ft. wide and 55 ft. long, resting on reinforced concrete piers, (Fig. 18); 46 tons of reinforcing steel was used in each slab.

The casings of two of the turbines are of cast iron made in six sections and are embedded in the concrete substructure of the power house. As can be seen from Fig. 19 this casing is bolted together by flanges on the outside, consequently the inside is smooth, and is designed for a gradual acceleration of the water as it passes around the volute. The intake is 10 ft. 6 in. in diameter, and the total weight of the casing is

about 263,000 lb. The runner is of cast iron, in one piece, having a maximum diameter of 10 ft. 6 in. and a total weight of 27,000 lb. The shaft is 25 inches in diameter and is provided with a lignum-vitae guide bearing. The draft tube is of the Moody spreading type which regains the whirl component as well as the axial component of the velocity of the water leaving

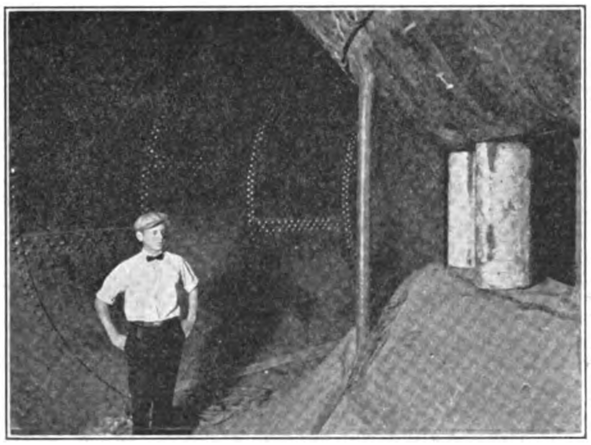

FIG. 20—INSIDE OF PLATE STEEL TURBINE CASE

the runner. This results in higher efficiency than the old type of curved draft tube, which does not regain the whirl. The spreading tube also eliminates surging and water hammer, which so often occur with curved draft tubes. These draft tubes are shown in section in Fig. 13.

A renewable ring is provided in the draft tube just below the runner, and the upper section of the draft tube is furnished with manholes for the inspection of tube and runner discharge. The total weight of each turbine is about 765,000 lb. The governors are located on the switchboard gallery with the gate-opening indicator and control stand. The regulating valve stand is on the main generator floor and is provided with plunger valves of the Johnson type. By this means the operation of changing the unit from hand to governor control is easily affected, all valves operating simultaneously.

The other turbine casing (Fig. 20) is made up of a number of conical steel plate sections riveted together, the casing being riveted to a cast-steel speed ring. The runner is of cast iron bolted to a cast-iron hub keyed to the tapered end of the shaft. A lignum-vitae guide bearing is mounted directly above the turbine. The turbine discharges into a single draft tube of the White hydraucone regainer type. Reference to Fig. 13 will make the construction clear. By the use of the hydraucone or spreading draft tube about 80 per cent of the velocity head in the discharge is recovered, whereas with the old type of curved draft tube a large proportion of this velocity head is always lost. Tests show that over 91 per cent of the total energy in the water is delivered at the generator terminals and the turbines themselves have an efficiency of 93 per cent. The fluid used in the governors is about 99 per cent water and 1 per cent oil, supplied from a central pressure system. Pressure of 115 lb. for operating the governors is maintained by static tanks at the top of the cliff. Should for any reason the fluid supply to the governors fail, they may be operated with water taken from the penstocks.

Each of the three generators is designed for a capacity of 32,500 kv-a. and generates 12,000-volt, three-phase, 25-cycle current when operating at 150 rev. per min. Although designed and built by different companies, each machine has about the same external appearance, and to this end the manufacturers cooperated so that the installation presents a uniform appearance. (Fig. 21).

As to the internal construction of the generators the engineers of the manufacturing campanies were left at liberty to follow their own ideas regarding details, the main restriction being that the electrical characteristics of the three machines must be such that they would operate satisfactorily in parallel. A box frame of usual design, 21 ft. 6 in. outside diameter, cast in sections, is used for the stator. Both ends of each phase winding are brought out so that a balance system of relay protection can be used. The windings are connected in star and the neutral grounded through a resistance of approximately 5 ohms, obtained by using a water rheostat.

The shafts are 27 inches in diameter below the rotor and are fitted with a 45 in. forged-on steel flange, for bolting to a corresponding flange of the turbine

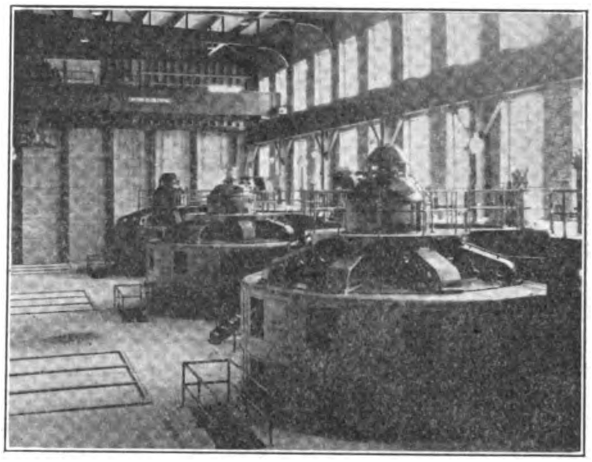

FIG. 21—INTERIOR OF STATION NO. 3 EXTENSION AFTER PLACING OF VENTILATING HOUSINGS AROUND GENERATORS

shaft. On the upper end of the shaft is the Kinsbury thrust bearing, carried on a bridge having eight radial arms. Each bearing is 49 inches outside diameter, and carries a load of approximately 470,000 lb., 100,000 lb. of which is due to the water thrust on the turbine runner. Directly under the thrust bearing is the upper guide bearing, which is 26 inches in diameter and 36 inches in length. The thrust bearing runs in a bath of oil supplied from a central

system. No water cooling coils are provided in the thrust-bearings housing, the oil being cooled and filtered in the central system.

To bring the rotating element to rest after the turbine gates have been closed, and also to prevent the rotor from turning in case of leaks through the gates, brakes are installed on the generators. These brakes are operated by compressed air, from a valve mounted on the hand-control stand located near the governor.

Ventilating air for the generators is taken into the machine from the generator room and also from the pit under the machine. The amount of air required by the different machines to carry off the heat varies from 70,000 to 90,000 cu. ft. per min. Each generator is surrounded with a steel plate housing, as indicated in Fig. 21, which connects to a duct system through a fan. In the summer months the ventilating air can be discharged outside the station. In the winter months part of it will discharge into the station and control room for heating, and the remainder will go to the ice runs. The average efficiency of the three generators at normal load and 90 per cent power factor is 98 per cent.

The leads from the generators go to an oil switch located in a terminal building on the top of the cliff above the power house, and then directly to a six-circuit transmission line carried on steel towers that runs to the Echota substation, three miles away.

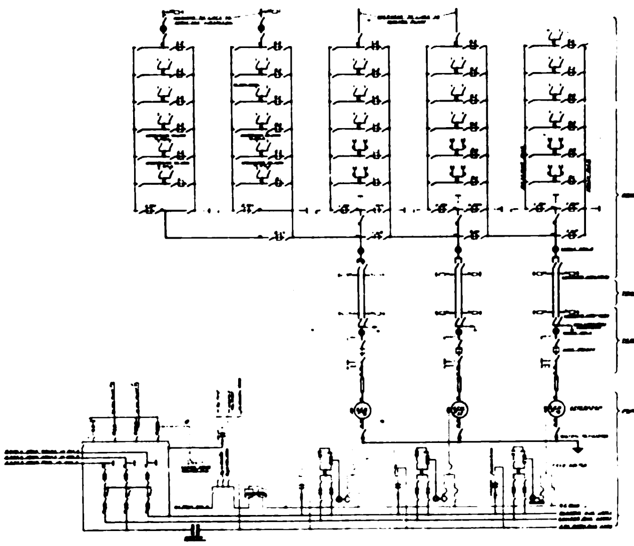

Fig. 22—One-Line Diagram of Connections, Station No. 3 Extension Development

These generator oil switches are automatically tripped by inverse time-limit relays when overloads occur outside the generators. In case of trouble within the generators the switches are opened instantaneously and the field circuit is killed by a balanced relay system of protection operated from current transformers in the generator leads differentially connected. Current transformers and inverse time-limit relays, protect each generator from overloads.

At the top of the cliff above the main generating station is the control building. On account of the simplicity of the switching arrangement, shown by the wiring diagram, Fig. 22, the control is greatly simplified, as is clearly indicated in Fig. 23. When a switch is

Fig. 23—Control Room Showing Panels for Control of 100,000 H. P. Station No. 3 Extension

opened, an annunciator on the control board shows the relay that operates it, thus indicating the source of the trouble. In each of the generators are 18 temperature indicators located at different parts of the stator windings. Six of these in each machine, that show the highest temperatures, are connected up to an indicator in the control room.

Excitation for the alternators is obtained from 2200-volt induction-motor-generator sets. Each exciter is of 225-kw. capacity, shunt-wound with interpoles, and generates 220 volts. The induction motors can be supplied from three separate and distinct sources, any one of which can be connected to a duplicate set of busses, and the 2200-volt induction motors, driving the exciters, connected to these busses through selector oil switches. An emergency source of excitation may be obtained from direct-current busbars in Station No. 3. This circuit is connected through a field rheostat to a busbar, to which the field coils of any one of the alternators may be connected in case of failure of its motor-generator exciter.

In laying out the station, effort was made to divide the electrical and mechanical operating functions. Electrical operation is centered in the control room and the mechanical in the station. How successful havy been the efforts to simplify operation is evidenced by the fact that a station of a normal operating capacite of 100,000 kw. is being operated by three men on a shift. The general external appearance of this station and its relation to Station No. 3 are shown in Fig. 24.

Transmission Line to Echota

The transmission line has a length of 16,000 ft. and runs from the terminal building up the canal to the river, thence following the bank past the plant of the old Niagara Falls Power Company (now known as the

Niagara Plant) and finally turning away from the river again at Echota to connect with the Echota substation.

The solution of the transmission problem was greatly facilitated by the consolidation of the two power companies, as land for the location of the line for the

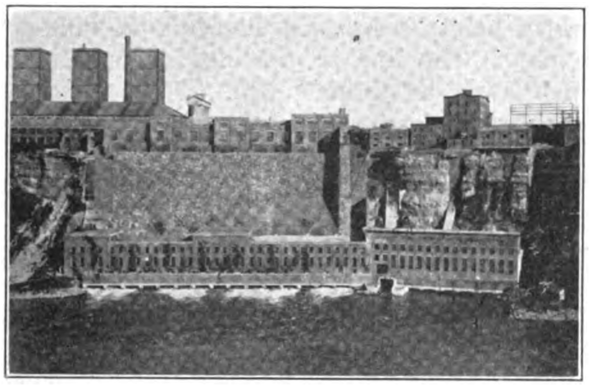

FIG. 24—VIEW OF STATION NO. 3 AND EXTENSION FROM CANADIAN SIDE OF NIAGARA RIVER

greater part of its length was already in possession of one or the other of them. For a distance of approximately 4000 ft. through the heart of the city, however, it was necessary to make use of the property already occupied by the hydraulic canal. This was accomplished by means of steel cantilevers anchored into massive concrete foundations on one bank of the canal, upon which were erected the six-circuit transmission towers.

For the greater part of the distance it was found necessary for only the narrow bases of the towers to be placed over the canal right-of-way, easement being obtained from abutting property owners for the

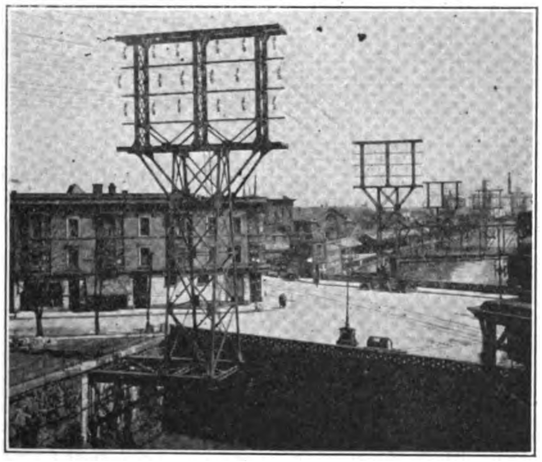

FIG. 25—TRANSMISSION LINE CROSSING STREET INTERSECTION SHOWING LONG CANTILEVER FOUNDATIONS

overhanging portion of the construction. At the large bridge spanning the canal at the junction of Third and Niagara Streets, however, this was not possible, and it was necessary to place two towers entirely over the canal. This was accomplished by means of long cantilevers extra heavily braced, as shown in Fig. 25.

The main horizontal members of this structure are composed of two 30-in. I beams, each 60 ft. long,

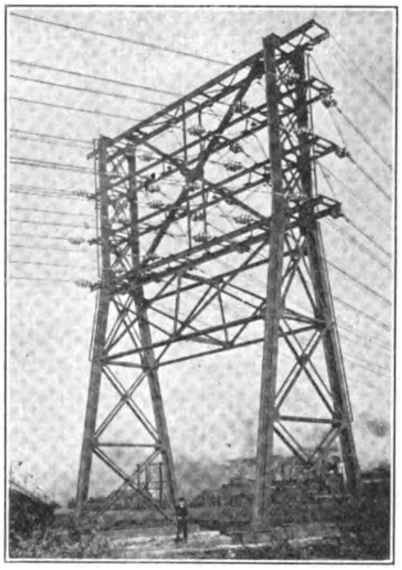

FIG. 26—PORTAL ANCHOR TOWER

placed side by side. Thirty feet of these beams is buried in the massive concrete foundation, the other 30 ft. projecting out over the canal. In these structures the center line of the towers is 25 ft. from the face of the canal wall. A heavy brace was added to these special structures to give stability and rigidity, although not needed for strength. In the case of the short cantilevers the brace was omitted.

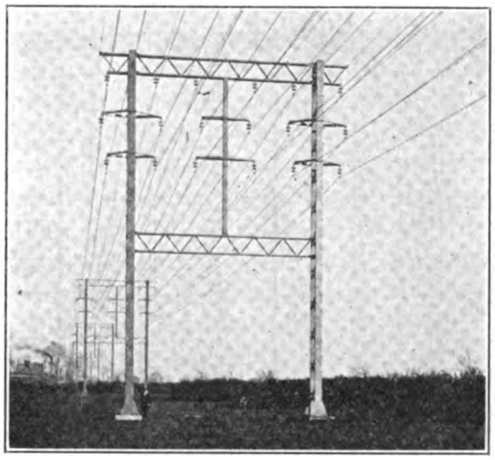

FIG. 27—FLEXIBLE PORTAL TOWER

In addition to the special narrow-base towers used on the canal section, the local conditions called for the use of several other types of structure, two of which are shown in Figs. 26 and 27. The portal type of construction was used for the section along the river bank where the line is built over a future street.

The line comprises six three-phase circuits, each

consisting of 500,000-cir. mil stranded medium hard-drawn copper. At present two circuits are used for each 32,500-kv-a. unit at 12,000 volts, but clearances are provided for 66,000 volts.

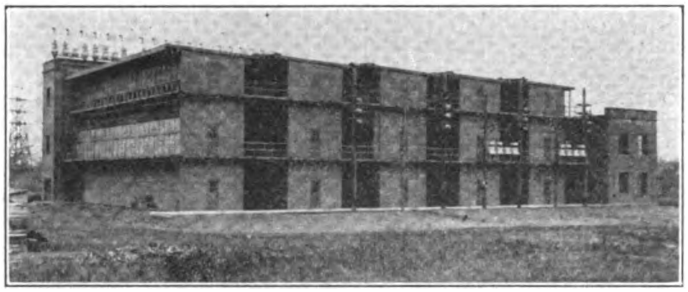

FIG. 28—ECHOTA DISTRIBUTING STATION SHOWING OUTGOING OVERHEAD LINES
Most of the feeders leave the station underground

Owing to the fact that this line passes through the business portion of a busy city, special precautions were taken to guard against failure. Each conductor is strung for a maximum tension under worst conditions of wind and ice of 6000 pounds. At strain towers double-strain insulators are used. Short spans, not exceeding 350 ft., were used as a further contribution toward safety and stability.

The line is insulated with substantial spider-type suspension insulators, two units being used in suspension strings and three in strain. On the canal section, because of the peculiarities of the right-of-way, it was impossible to avoid a number of small angles, at which points suspension strings with hold-downs were used. The line is protected against lightning by five overhead ground wires, $\frac{3}{8}$-in. copper-clad wire being used for this purpose.

ECHOTA DISTRIBUTING STATION

The Echota substation is intended to serve three functions—(1) to subdivide and distribute the power from the new plant, (2) to serve as a clearing house for the output of the five generating stations, aggregating 400,000 h. p., and (3) to act as a future step-down transformer station.

Inasmuch as the primary function of this station is to distribute the power of the new plant, it was decided to preserve the unit arrangement in its construction. The station was accordingly laid out in units of a nominal capacity of 32,500 kv-a. Five of these units were constructed, three for the new plant and two for interconnection with other generating stations. A

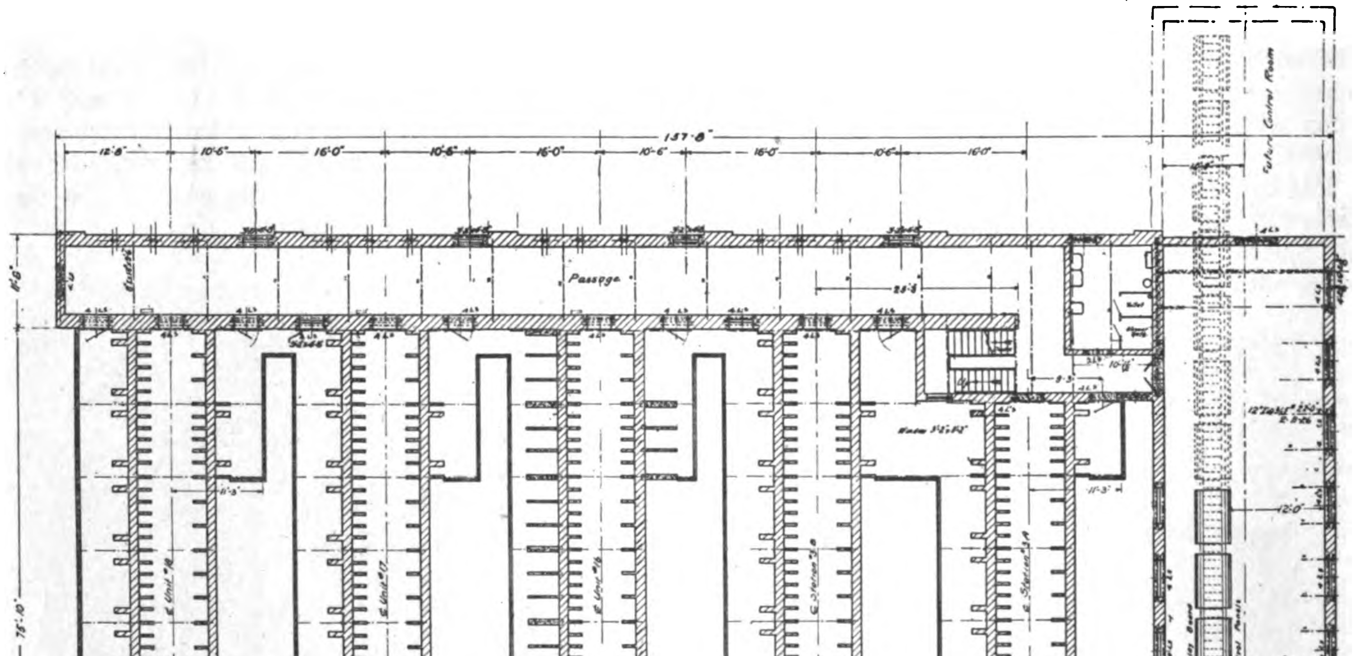

FIG. 29—PLAN OF ECHOTA DISTRIBUTING STATION—SECOND FLOOR

control building containing the switchboard apparatus was also erected. The general wiring diagram, Fig. 22, shows the arrangement of the main circuits; the physical layout of the structure is similar to that of the diagram. The general scheme is that of a main tie bus running lengthwise of the building with the unit lateral busses joining it at right angles.

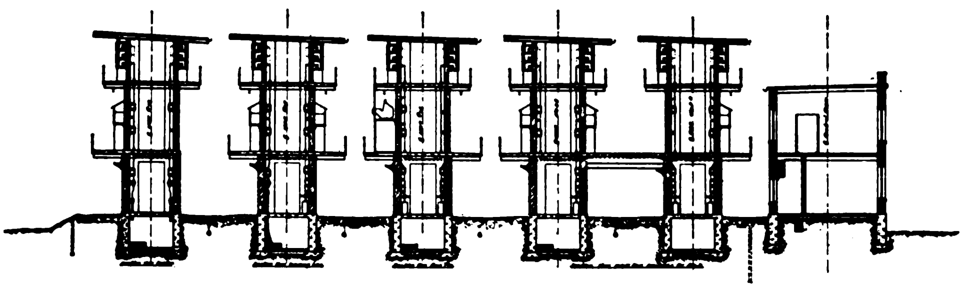

FIG. 30—LONGITUDINAL SECTION OF ECHOTA DISTRIBUTING STATION—LOOKING WEST

The five units or bays and the control building are connected at one end by a narrow building or passageway which contains the incoming line protective equipment and serves as a distributor for the control wiring, piping, etc., and as a means of access between the control building and the several unit bays. The main operating portion of the station is concentrated on the second floor which contains the oil switches with their disconnecting apparatus and the control room. Under each of the unit bays is a subway for distribution of cables. This connects at each end with longitudinal subways.

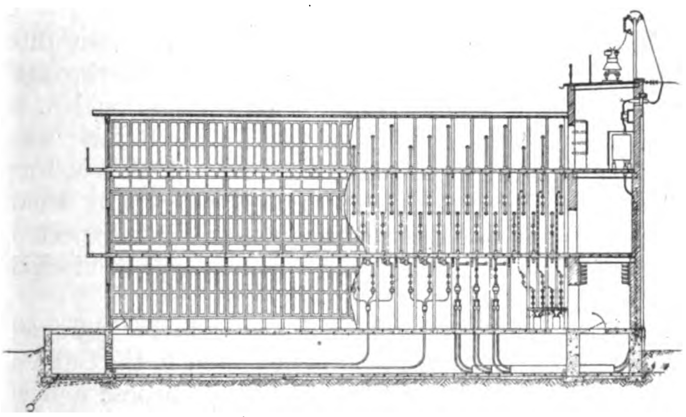

FIG. 31—CROSS-SECTION OF BUS STRUCTURE THROUGH ONE BAY OF DISTRIBUTING STATION—LOOKING SOUTH

A radical departure from the usual station construction is the placing of all oil circuit breakers on the outside of the building walls; in other words, the main bus and switch structure walls are utilized as the walls of the building, all high-tension connections being upon the inside, where they are thoroughly housed and protected against the elements, and the oil switches upon the outside, where explosions and oil fires can do a minimum of damage. Galleries are provided on the outside for access to the oil switches which are protected from the weather by suitable housings.

Each incoming line, after passing through a set of choke coils for lightning protection, divides, one side going through an oil circuit breaker to the main bus, the other side through a similar breaker to the unit reserve bus. In each bay provision is made for six outgoing feeders. Each of these connects to the main bus through an oil circuit breaker and to the reserve bus through disconnecting switches. The function of the reserve bus is twofold—(1) It serves as a true reserve bus from which all feeders can be supplied temporarily through the reserve-bus switch. (2) The reserve-bus switch serves as a substitute switch for any individual feeder switch which may be out of service. In this manner duplication of the switching facilities is obtained without duplication of oil switches on each feeder. Provision is made for the installation of reactors between bays, and these will be installed as soon as they are required.

Owing to the great importance of this station in the general scheme of distribution, both present and future, it was determined to insure the greatest possible degree of reliability in the oil switches. Accordingly both of the chief manufacturers were asked for a recommendation on this basis, resulting in the proposal of two radically different types of oil switches, namely type *C O*-2 and type *H*-9. Owing to the absence of operating experience with these switches, it was found impossible to establish definitely the superiority of either one over the other, and it was decided so to construct the station that either one could be used. This was accomplished by slight modifications in the standard assembly of both types, and it was decided to install at the start a number of each type in order that actual operating experience might be had with both.

The doors covering the disconnecting switches of each circuit breaker are all operated together so that it is impossible for an operator to obtain accidental access to a disconnect of an adjacent circuit breaker. These doors are mechanically interlocked with the circuit breaker so that they cannot be opened until the corresponding oil switch is in the open position.

The switchboards consist of vertical panels and are divided into five sections corresponding with the five main bays, in addition to a house-service section. Back to back with the control boards, with a 4-ft. aisle between them, are the relay and terminal boards. Each instrument and relay is provided with a complete set of calibrating link terminals mounted upon small panels on the rear of the main panels.

The vertical wiring on the back of the switchboards is carried in troughs 3½ in. wide, made up of two ¾ in. angle sides with asbestos board back and removable

sheet-metal covers. The advantages of this system of wiring are safety, accessibility, neatness, ease of installation and flexibility.

At their point of departure from the board, all control wires pass through terminal links and are then carried in steel pans or troughs mounted one above another on brackets fastened to the wall of the building. By this construction the control wiring is made accessible practically throughout its entire length, and at the same time an enormous amount of conduit work is avoided.

For the operation of the control circuits there are provided two 14-kw. motor generator sets and a 120-ampere-hour, 220-volt storage battery.

The incoming lines from the new generating station are each equipped with overload, ground and reverse-power relays. These relays are arranged to trip both the main and reserve-bus circuit breakers. The bus-tie switch is equipped with overload relays. Feeder switches are relayed in two different ways, according to the nature of the feeder supplied. In certain cases where a feeder consists of four parallel cables, split-conductor protection is provided between the two pairs of cables by means of suitably connected current transformers and low-current relays. In other cases ground relays are installed, connected in the current transformer neutrals. Overload relays are also installed on all feeders. All relays are of the induction type, the five-ampere size being used for overload and the one-ampere size for differential and ground protection.

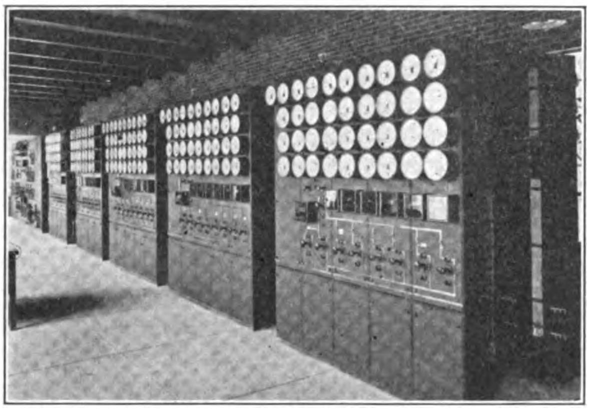

Fig. 32—Switchboard at Echota Substation

A somewhat unusual feature in connection with the relay system is the installation of annunciators on the switchboard with the drops connected in series with the tripping circuits of the various relays. By this means it is possible to know at once upon the tripping out of a circuit breaker just which relay was responsible. This immediately gives an indication of the nature and in certain cases of the location of the trouble. It also furnishes the means of keeping tabs on the operation of the relays. Although the station has been in operation only a few months, the value of this feature has already been amply demonstrated.

Further Development Authorized by Federal License

The completion in 1920 of Station No. 3 Extension for three 37,500-h. p. units provides for the utilization of the entire amount of water, 20,000 cu. ft. per sec., which is available under the existing treaty. But there has been, and with the return of normal industrial conditions there will be again, a demand for additional power.

Since, by Act of Congress creating the Federal Power Commission the U. S. Government assumed control of the Niagara River situation it became necessary that the Commission's approval be obtained for any further development of power. As no further water is at present available the only source of additional power is the use of some of the present water under increased head. Naturally, the least efficient of the existing plants would be the one first selected for obsolesence, which in this case is the "Niagara" plant, which, operating under an effective head of 140 ft. obtains but 12.1 h. p. per cu. ft. per sec. as compared to 21 h. p. per cu. ft. per sec. in the Station No. 3 Extension.

The economic reasons for the plan adopted for the re-development of this water have been given above and the Company is now proceeding under License from the Federal Power Commission with the construction authorized.

The power will be developed in a further extension to Station No. 3 along similar lines to those followed in the already completed extension.

The water will be brought from Port Day through a 32-ft. horseshoe-shaped tunnel at a depth of about 100 ft. below the surface of the ground. From this tunnel the water will be taken to the penstocks through a forebay similar to that provided for Station No. 3 Extension. The construction of this tunnel was started, with fitting ceremonies, on April 25th of this year, and the work is now proceeding rapidly from both ends and two intermediate shafts. It is expected that the first unit of this development will be started on or before May 1st, 1923.

A portion of the additional power to be obtained from this development will be delivered to the Buffalo General Electric Company. For this purpose a new 66,000-volt transmission line is now under construction from the Echota Station to the vicinity of the steam station of that Company which is located on the Niagara River about a mile below the Buffalo City Line. This new line will consist of two circuits of 500,000-cir. mil copper and will be capable of transmitting upwards of 100,000 h. p. to Buffalo. This line, unlike its predecessors, will take a direct route, first crossing the East arm of the Niagara River from the mainland to Grand Island, thence running straight across the island and recrossing the river to the mainland again between Buffalo and Tonawanda, whence it will extend to its terminus by the shortest available route. At the lower crossing the river is about 4000

ft. wide and the crossing will be made in two long spans of about 1600 ft. and two shorter anchor spans, with channel clearances of 75 ft. At the upper crossing the river is narrower and the crossing will be made in a single long span of about 1800 ft. with 115 ft. channel clearance.

Niagara Power in American Industry

In a condition of society where each man's livelihood depends upon his own unaided efforts, the state of civilization must necessarily be low and the majority of the population in poverty and misery. Conversely, the state of civilization will be the most advanced and the general well-being the greatest, where the ratio of usefully employed power to population is the highest. It follows therefore, that the ultimate state of civilization will depend upon the efficiency with which the country's *inexhaustible* power resources are made to minister to the needs of man.

It is profitable, therefore, to examine the uses to which our power resources are to be put, and particularly is it profitable to do this in the case of Niagara, the greatest single source of water power in North America. Here is a power stupendous in magnitude, absolutely continuous in character, easily developed, at a construction cost so relatively low that the electric energy cost to customers is the very lowest, and located in the midst of a large industrial population with abundant labor, adequate transportation, and a near-by market immediately available. Compare this with the large western powers, located in almost inaccessible fastnesses of the mountains and far removed from all those other factors necessary to industry, namely, labor, transportation, raw materials and market. The contrast is striking, and should rightly give us pause to consider the corresponding contrasts in the proper utilization of these diverse developments. In general, the western water power must be transmitted great distances and utilized in those applications where the value of the service will warrant the cost of such transmission. Not so, however, Niagara. Here Industry can come to the very doors of the power plants and obtain absolutely continuous power with no added expense for transmission.

It would seem, therefore, that Niagara was intended by Nature for application to these primary industries requiring continuous power at low cost, especially electrochemical and electrometallurgical processes, producing essential raw materials for use in secondary industries engaged in the manufacture of finished or semi-finished products. This is the destiny of Niagara. Not primarily in lighting the lamps nor in turning the wheels of industry is to be found the ultimate outlet for Niagara's steady energy, but in the production of the necessary *materials* of industry which can be produced in no other way.

Such has been, in fact, the principal use to which Niagara power has been put, and it is not entirely coincidence that the great industrial growth of America has been contemporaneous with that of the development of Niagara. To what extent, for instance, the development of the automobile industry has been dependent on Niagara power, we do not know exactly, but it has been estimated that the withdrawal from this industry of only three of Niagara's products, namely, ferroalloys, artificial abrasives, and aluminum, would both increase car weights and decrease production by about 80 per cent. What is true of the automobile industry is also true to a very great extent of all of our industries. Niagara might today be rightly named the "Mother of American Industry."

This conception of Niagara's destiny, however, has not always obtained. Before the discovery of these products, or of ways for their manufacture and use, Niagara's energy was thought of entirely in terms of turning wheels and illuminated houses and streets. So some of the earlier developments were predicated upon transmission but with the gradual unfolding of her peculiar genius, it has slowly come to be recognized that, like all good mothers, her most important duty is at home. Immutable economic laws will dictate that at home all her energies must ultimately be expended, "mothering" America's industries, but for some time to come there may not be a sufficient outlet for her energy in this direction.

During the three decades since the birth of hydroelectric development, we have been catching up with the demand and the development has been correspondingly rapid. As the capacity of America to absorb the products of those industries to which Niagara has given birth gradually becomes saturated, the rate of development will naturally become slower and more commensurate with the growth of population of the whole country, unless a new and broader outlet for her energies is developed. That those energies should be developed to the full, and that as soon as may be, is not to be questioned. Once it has been determined, as has now been done by the Federal Engineers, as to how much of Niagara's potential power may be put to work, there should be no delay. Every pound of water that can be spared but is permitted to pass without doing work when there is work to be done, means the unnecessary destruction of just so much of our limited coal supplies. Therefore, pending the time when all of Niagara's energy is needed at home for use in primary industries, such part as is not so needed should be employed, elsewhere if necessary, in secondary industries or in ministering to the comfort and convenience of the people in their homes. This is legitimate and feasible, but its consummation should be undertaken with caution.

It must be borne in mind that the attainment of our highest good must ultimately demand the most efficient use of this power. Nor is efficiency here meant in any narrow sense, but in the broadest sense of the greatest good to the greatest number. Within the next few

years we shall undoubtedly see great superpower transmission lines reaching out hundreds of miles from Niagara, putting her surplus power to work, but as the years roll on and the growth of our population creates

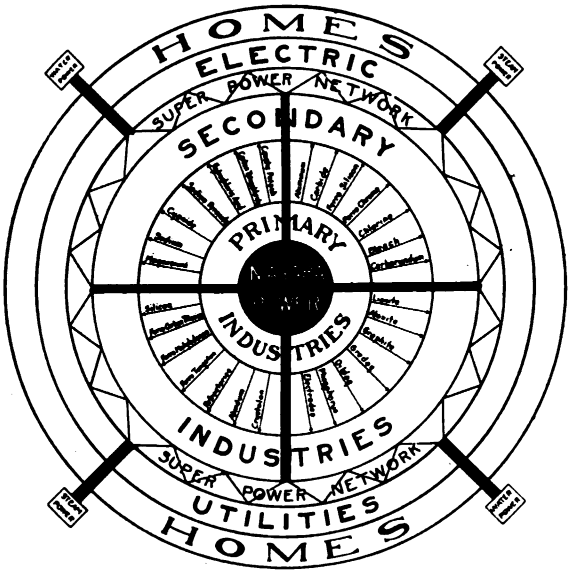

FIG. 33—NIAGARA POWER IN AMERICAN INDUSTRY

increasing demands for the peculiar products of Niagara's particular genius, we shall see this energy distribution gradually being drawn in. And creeping after it we shall see great steam plants slowly but steadily approaching Niagara, replacing in the homes and secondary industries, that energy which, as times goes on, can less and less be spared from the "mothering" home industries of Niagara.

So we shall finally reach the ultimate condition wherein Niagara shall become the center of a great industrial community. (See Fig. 33.) In an inner ring around the Niagara power nucleus will be the great primary industries producing the peculiar raw materials for which this power is necessary and which are themselves in their turn necessary to others. And surrounding this ring will be another and a wider ring of secondary industries obtaining their specialized raw materials and certain of their tools from the primary industries of Niagara and their power from a superpower network fed from those inherently variable power sources, both water and coal, such as are adapted to their needs. But connecting this superpower network with Niagara's power will also be transmission lines, and as the tide of industry ebbs and flows so will also ebb and flow the tide of power over these lines. Always, when the need demands, Niagara's power will be drawn back within the inner ring to do its own peculiar work which no other power can do, but when in the swing and surge of industry the home demand is lightened, out will go Niagara's power again over the interconnecting transmission lines to the beneficent work of saving coal by its use in the secondary industries and utilities. In this manner will Niagara's steady flow be kept continuously at work.

A 140,000-H. P. HYDROELECTRIC PROJECT FOR FORMOSA

The Bureau of Foreign and Domestic Commerce has received from Consul Henry B. Hitchcock, Taihoku, Taiwan (Formosa), a copy of the specifications and drawings for the mechanical and electrical equipment of the Jitsugetsutan (Lake Candidius) hydroelectric project to be constructed by the Taiwan Electric Power Co., which has been forwarded to the bureau's New York office, 734 Customhouse, in order that it may be more readily consulted by interested persons. (Reference should be made to File No. 29632.)

The generating station is to consist of six 20,000-kilowatt alternating-current generator units directly coupled with Pelton type waterwheels operating under a mean actual head of about 1370 feet. In addition to the main waterwheels and generators, the specifications also call for water-driven exciter units, penstocks, governors, valves, eighteen 7400-kv-a. step-up transformers, switchboard, and switching equipment, and other auxiliary apparatus, including a traveling crane. For the two substations there will be required twenty-one 7000-kv-a. step-down transformers, three synchronous condensers, and the switching and other auxiliary equipment in connection therewith.—*Commerce Reports.*

ELECTRIFICATION IN BRAZIL

Traction Improvements in Pernambuco. According to telegrams from Pernambuco, says *Commerce Reports*, the tramway company of that city has just installed a large up-to-date turbine with a capacity of 3000 kilowatts, which will double the capacity of the old plant. Installations of substations at Gracas were also inaugurated for furnishing light to the districts of Torres, Zumby, Casa Amarella, Pranamerin Espinheiro, Encruzilhada, and Capunga.

Electrification of the Paulista Railway. It is understood that the initial order which has been placed in the United States by American contractors for the electrification of the Paulista Railway comprises material sufficient to take care of the first 45 kilometers, the Jundiahy to Campinas section. Two of the four engines to be furnished by another American company are passenger locomotives of 2000 horse power weighing 121 tons each, one being capable of a velocity of 104 kilometers on a 1.60 meter gage. The remaining two are freight engines of 1500 horse power, weighing 87 tons each, with a speed of 64 kilometers per hour. An aerial circuit of 3000 volts continuous current will furnish the motor force with transmission to the trolleys. The entire electrification when completed will cover about 160 kilometers.

Technical Committee Annual Reports, 1920-1921

MINES COMMITTEE

To the Board of Directors:

THE Chairman of the Mines Committee of the A. I. E. E. for 1920-21 has had the honor of being also the Chairman of a similar committee, the Mine Equipment Committee, of the A. I. M. E. It has been the endeavor during the past year to have the two Committees work together since the object of these Committees is very much the same.

A meeting of the Committees was held in Chicago in November of 1920 at which time it was decided that one of the best methods to work together would be to foster joint meetings of the local sections of the A. I. E. E. and A. I. M. E. By these meetings, it was hoped that various engineers in the local sections interested in mining subjects could be brought together and not only become better acquainted, but could be greatly benefited by the interchange of ideas and by the discussion of papers presented on mining subjects.

It was also decided that both Committees should encourage the writing of papers on mining subjects to be presented, either at local section meetings or at the National meetings.

It was also decided that these Committees should work in conjunction with the American Mining Congress and the American Engineering Standards Committee in developing standard practises for both coal and metal mines in the United States.

The first combined meeting of the local sections was held in Pittsburgh on January 18, 1921, the meeting being held at the Bureau of Mines. An afternoon technical session was held at which a paper was presented by F. W. C. Bailey on the subject of "Power Rates for Coal Mines." This paper was well received and produced an active discussion. Following the afternoon meeting, a visit was made through the Bureau of Mines Buildings, after which dinner was served at the same place. The evening session was held in the auditorium of the Bureau of Mines and a paper was presented on "Gathering in Coal Mines" by R. Kingsland of the Consolidation Coal Company of Fairmont, W. Va. Both afternoon and evening papers have been submitted to the Publication Committee of the A. I E. E. for publication in the JOURNAL.

A second combined meeting has been arranged to take place in Chicago on April 25th. This meeting will be participated in by the Electrical Section of the Western Society of Engineers, the Mining Section of the Western Society of Engineers, the Iron & Steel Electrical Engineers of Chicago, and the Chicago Section of the A. I. E. E. Two papers will be presented as follows: "Diversity Factor of Coal Mining Loads" by Carl Lee, Electrical Engineer, Peabody Coal Company; and "Power Distribution Systems for Coal Mines," by W. C. Adams, Allen & Garcia Company.

The Philadelphia Section has agreed to have a combined meeting, but wishes to put it off until the Fall of this year as it has recently held two combined meetings with the Engineers Club of Philadelphia and does not wish to have another combined meeting in the near future.

It is hoped during the present year to have additional combined meetings in some of the Western States.

PROGRESS OF ELECTRIFICATION OF MINES

Until recently, the coal mines of the United States have been particularly active and the price of coal has been such that most mining companies have had a fairly profitable season. This has enabled a great many mines to establish improvements in the way of electrifications that they had been looking forward to for some time. A few years ago, the central stations were having a very difficult time to persuade the coal mining companies that they could sell them power cheaper than the coal mining companies could produce it themselves. Recently, the conditions have been somewhat reversed and in many cases the central stations have found it necessary to refuse coal mine loads on account of having no surplus capacity. In the large majority of cases, it is not difficult to show a coal mining company that it can operate its mines more economically from purchased power than from its own power plant.

Isolated power plants are being installed in some cases where central station power is not available, and also where the operator feels that central station power is not as reliable as his own plant would be. This is particularly true where the coal mining plant is throwing away fairly high grade waste coal and where a standby steam plant is kept in operation to take care of operating the auxiliary hoist and fan in the case of power failure. The tendency in isolated plants is to install geared turbines up to a capacity of 500 kw., and above this capacity the direct connected a-c. turbine. The turbine installation makes a much simpler plant to operate when compared to the old engine-type stations and turbine plants have records of long continued operation with practically no interruptions and a very low cost of operation.

The synchronous converter is becoming more popular each year for mine service. This is due largely to the improvement in converter design which makes this apparatus as strong and simple to operate as the motor-generator set, with the advantage that it takes up less room and is much more efficient.

The most important development during the last year has been that of the automatic substation for

mine service. One of these plants has been in successful operation for several months and several more are being built. The automatic substation has the advantage that it performs all of the operations that are necessary in a substation at the proper time and much better than could be accomplished by manual operation. The automatic equipment makes no false moves and in case of trouble of any kind, acts on the safe side and shuts down the station if necessary. It is felt that in the future, the automatic substation will play a very prominent part in mine installations.

The electric hoist is rapidly replacing the steam hoist to such an extent that a steam hoist is rarely installed in a new mine. The large majority of hoists for coal mines is of the alternating current type using a wound rotor induction motor with the magnetic type of control. Recent improvements in the control and safety devices make the electric hoist practically fool-proof and serious accidents are of very rare occurrence. A few installations have been made using the Ward Leonard system of control and flywheel motor-generator set. The Ward Leonard control is necessary where very fast hoisting cycles are required and the flywheel is necessary where the customer is penalized for momentary peaks.

The past year has seen a continuation of the develoment and application of magnetic control to mine locomotives. The demand for the individual capacity of mine locomotives has been increasing until it becomes very difficult to supply a drum type controller for 250-volt service. The magnetic type of control is a very satisfactory solution for this problem, and a number of such locomotives have been recently installed. The large unwieldy drum controller is replaced by a small master controller which takes away a considerable element of danger from the motorman's position. The main controller, consisting of magnetic contactors and reversers, can be distributed back in the locomotive, preferably suspended from the underside of hinged covers which enables the equipment to be inspected readily and repaired. The use of magnetic control has greatly simplified tandem operation. With drum-type controllers, it is necessary to mount a large four-motor controller on the primary unit, a two-motor controller on the secondary unit, and the two units connected together by a large number of heavy power cables, when tandem operation is required. With magnetic control, the two units are identical and the only connection between the units required is one power cable and a control cable consisting of nine control wires. The advent of magnetic control makes it necessary for the mining companies utilizing it to furnish better voltage regulation for the mine circuits which in turn will save considerable power loss and also keep down repairs on mining equipment, which repairs in the past have been largely due to poor voltage regulation.

A number of improvements and new features has been added to the construction of mine locomotives during the past year. Of these, the most important are the substitution of the leaf type spring for the helical type of spring, the installation of the end-thrust type journal box, the use of equalizers on two-axle locomotives, the application of detachable rims to locomotive wheels and the more general application of dynamic braking on mine locomotives. The value of these various improvements can only be determined after a thorough trying out.

Metal Mining Industry

The metal mining industry has been particularly quiet during the last year due to the low value of practically all metals excepting iron and steel. In the copper mining industry, one of the recent improvements has been the installation of a motor-driven turbo blower to replace a Root type for such service as air for cupolas, converters and flotation cells. These blowers require high-speed synchronous motors which are of the turbo type.

The metal mines have been doing a little work toward revamping their plants and installing new equipment, but this, of course, has been greatly hampered by the poor market conditions.

Shovels and Drag Lines

Electric power is gradually replacing steam on shovels and drag lines where electric power is available. There are at present, two systems being used, one the a-c. in which wound rotor induction motors are used to operate the various parts of the shovels and drag lines. The other system is to use d-c. mill-type motors receiving power from a synchronous motor-generator set. The motors are operated by rheostatic control. A recent development is being watched closely by all engineers interested in the handling of shovels and drag lines. This consists of d-c. motors on the shovels receiving power from the synchronous motor-generator set with a separate generator for each motor. Ward Leonard control is used and the advantage of the system claimed is that all rheostatic losses are eliminated and the momentary peaks are kept off the power system. It is hoped that during the next few months sufficient data will be obtained to determine the feasibility of this system and its economy when compared with the other two systems.

Car Dumper

During the past year, some very important installations of car dumpers have been made at the Atlantic ports. These car dumpers are increasing in size from year to year and there has recently been placed in operation at Baltimore the largest car dumper as yet constructed. This car dumper requires four of the largest mill-type d-c. motors built on the cradle hoist, all operated from one master controller. It is felt that if these car dumpers increase further in size,

it will be necessary to utilize the Ward Leonard control system.

A very interesting installation of grain car dumpers has been placed in operation during the past year at Baltimore. This car dumper takes care of unloading box cars filled with grain, with practically no manual labor. All motions are interlocked, so that it is practically impossible for the operator to make the wrong move and cause any considerable damage.

Ore and Coal Bridges

There has been little change in the type of equipment for ore bridges during the past year, but in regard to coal bridges, the largest one ever built has been installed and placed in operation by the American Bridge Company at the By-Product Coke Plant of the United States Steel Corporation at Clairton, Pa. This bridge is by far the largest ever constructed and it is expected to take care of a very large tonnage of coal from barges in the river to storage piles, in order to insure a steady supply of coal to the coke ovens at Clairton, which is the largest by-product coke oven plant in the world.

By-Product Coke Oven

During the past year, an advance has been made in the design of locomotives for quenching service in and about by-product coke ovens. The latest type of locomotive is equipped with electropneumatic control having not only automatic acceleration, but also the ability to operate on any notch. These locomotives weigh about 25 tons each and have a number of new features in regard to mechanical arrangement of parts that are quite an improvement over the past type of construction for quenching locomotives.

The coke-loading locomotives at the Clairton plant are of the combination type, using remote control while the coke train is being loaded. These locomotives have been operating very successfully during their second year, and have affected a large saving over the older scheme of using steam locomotives, or the cable haul. It is felt that in the future there will be a considerable call for the remote control of locomotives and cars, not only around coke plants, but also where large amounts of material are to be handled over fairly great distances.

Graham Bright, *Chairman.*

INSTRUMENTS AND MEASUREMENTS COMMITTEE

To the Board of Directors:

The Instruments and Measurements Committee submits the following report containing a brief statement of its own activities, brief mention of significant papers issued during the year and as comprehensive a statement, as can be briefly condensed into a report of this character, of the progress in the electrical field covered by its title.

The committee arranged for a number of papers for presentation at the Midwinter Convention in February and had a session assigned to it. The papers presented at the session are as listed below:

Regulation of Frequency for Measurement Purposes, by B. H. Smith.

Measurement of Relative Eddy Current Losses in Stranded Cables, by J. A. Cook.

An Electromagnetic Device for Rapid Schedule Harmonic Analysis of Complex Waves, by F. S. Dellenbaugh, Jr.

The Limitations of the Stopwatch as a Precision Instrument, by A. L. Ellis.

The paper by Mr. A. L. Ellis, listed above should be considered as related to the paper by Mr. H. B. Brooks which was presented last year under the title of the Accuracy of Commercial Electrical Measurements. This paper by Mr. H. B. Brooks, it was hoped would contain an analysis of the characteristics and limitations of the stopwatch, as well as the purely electrical instruments. This could not be included, however, and it was felt by the committee this year that it would be desirable to have such a paper on record. The paper was, therefore, prepared by Mr. A. L. Ellis and serves very well indeed to supplement or complete the very thorough paper presented the year before by Mr. H. B. Brooks.

In addition to the papers referred to above, other papers or articles are listed below which seem of sufficient significance and value to include in this brief report. It is not intended or even possible to make a complete bibliography of all papers or articles which may have appeared during the past year, relating to the general subject of instruments and measurements, but as stated above the following brief mention seems of value in this report:

The Corona Voltmeter and the Electric Strength of Air, by Whitehead and Isshiki, in the Journal, A. I. E. E. for May 1920. The proposed increase of transmission line voltages makes the measurement of crest voltage of increasing importance. In this paper Dr. Whitehead describes refinements in the corona voltmeter and a modification of the previously accepted law of corona.

"New Current Balance for Calibration Work," by Otto A. Knopp, *Electrical World,* Vol. 75, May, 1920. This apparatus makes it possible to obtain a large number of standard values of current from a single value calibrated by independent means. It is especially suitable for central station use in the calibration of a-c. ammeters.

Portable Oscillograph, by J. W. Legg, Journal, A. I. E. E., July, 1920. The oscillograph in its previous forms is a valuable instrument, but is not well suited to field work. The form described by Mr. Legg replaces the arc lamp with a tungsten lamp operated at very high efficiency, and excites the galvanometer magnets from a storage battery. A number of ingenious features are included in order to control exposures.

A Dynamometrical Comparator, by Edy Velander,

JOURNAL, A. I. E. E., July, 1920. The accurate measurement of small alternating currents presents considerable difficulty. This comparator, in connection with a d-c. potentiometer, is stated to give accurate measurements of currents from 5 to 50 milliamperes, at frequencies up to 2000 cycles.

"Permanent Magnets in Theory and Practise," by S. Evershed, *Journal*, Inst. Elec. Eng. (London), Sept., 1920. This paper is primarily of value to the designer and maker of electrical instruments and meters.

"Magnet Steel," by Honda and Saito, *Electrician*, Dec. 17, 1920. This paper gives the properties of a remarkable steel for permanent magnets, having a very large coercive force and intensity of residual magnetization.

The method of making large ammeter shunts which was mentioned in a paper before the Institute in February, 1920, has been used by A. B. Field in England, who gives particulars in a paper in the *Journal* Inst. Elec. Eng. for August, 1920. This paper and its discussion are particularly valuable in view of the increasing size of totalizing shunts used to measure the direct current output of synchronous converters or the total direct-current output of substations.

Wattmeters have been made on the electrodynamic, electrostatic, and electrothermal principles. To these may now be added the "vibration wattmeter," announced in a paper by Biermanns in *Archiv fur Elektrotechnik* for August, 1920. This is similar to a permanent-magnet moving-coil vibration galvanometer, but has two windings in the coil, one used as a current coil and the other, with a non-inductive external resistor, as a voltage coil. Two readings are taken, for the second, the relative direction of current in the two windings is reversed. The power is proportional to the difference of the squares of the deflections. It is said that as low as 10^{-13} watt can be measured.

Considering the question of new developments in apparatus, the makers of watthour meters and demand meters advise, in general, that the effort, during the past year, has been mainly expended in restoring the pre-war quality of output, rather than any considerable amount of new development.

Apparatus continues to be developed for making measurements either of kilovolt-amperes or of the inductive component to be used in connection with rates including a power factor charge.

One of the makers of indicating instruments reports the development of a new line of small size portable instruments (ammeters, voltmeters and wattmeters). These instruments would be of particular interest to those desiring small but accurate and serviceable instruments which can be carried in the pocket or the tool kit.

The makers of precision and recording instruments report the continued development and application of electrical measuring methods and instruments to problems and functions not fundamentally electrical. While electrical methods have been used for years in making laboratory measurements of quantities not electrical, the significant fact now is the wider application of electrical measuring devices for recording and for the actual quantitative control of industrial processes.

Automatic Gas Analysis. Apparatus is now available for the automatic recording of gas analysis. The operation of the apparatus depends on the thermal conductivity of the gases being analyzed. The apparatus is arranged so that variations in the thermal conductivity of the gas being analyzed will cause corresponding variations in the temperature of a resistor having a high temperature coefficient of resistance. The variations in this resistance are recorded by an automatic Wheatstone bridge recorder. Such apparatus finds a valuable application in plants manufacturing hydrogen, oxygen and other gases for commercial purposes.

Electrical Temperature Controller. Equipment has been developed for controlling the temperature of any piece of operating equipment, and particular effort has been made to obviate the trouble due to "hunting" occasioned by the lag between the change in the quantity which is causing the heating and the corresponding change in the temperature of the body under control. The device in question is designed to control the input of the quantity causing the heating in accordance, not only with the actual temperature of the body, but also in accordance with the rate of change of the temperature of the body itself. For instance, if 100 deg. cent. is the limit of temperature desired, it is possible to measure the rate at which the temperature is approaching the 100-deg. point so that the load may be cut off at the proper instant to allow the temperature to drift up to a final limit of 100 deg. cent. without exceeding this value.

The definition of power factor in polyphase circuits which was active last year and mentioned in last year's report as being in preparation by a Special Joint Committee, can be considered as now in the hands of the Standards Committee. A session at last summer's convention of the Institute was devoted to the discussion of this subject and as a result of this open discussion, the Special Joint Committee prepared certain definitions which were reported to the Standards Committee.

The question of standardization of the nomenclature of commonly used electrical instruments and measuring devices was discussed at a meeting of this committee during the year and preliminary steps have been taken, which it is hoped will ultimately lead to the standardization of many names and terms. The work which has been done to date has been confined to the members

of the committee only, in preparing as complete a list as possible of the names and terms to be discussed and standardized. No further report can be made at this time but a brief mention of this activity, however, seems desirable with a recommendation that the succeeding committee continue the work during the coming year.

F. V. MAGALHAES, *Chairman.*

EDUCATIONAL COMMITTEE

To the Board of Directors:

The Educational Committee has been greatly handicapped by the wide geographical distribution of its members, the work being delayed by tedious long-distance correspondence.

The Committee held a meeting in Chicago on November 12, 1920, Mr. Schuchardt presiding, and while only three members were present a plan for the year's work was outlined which later received the approval of all the members. The Committee wished to determine in what respects the technical graduates failed to meet the expectations of their employers and to obtain definite suggestions as to how the product of our Engineering Colleges could be improved. For this purpose a circular letter was prepared and sent to over a hundred prominent electrical engineers, requesting their opinions and criticism. A summary of the replies and a discussion of the suggestions received will be prepared for publication in the JOURNAL.

The Committee believes that a better correlation than obtains at present in curricula, in methods of giving instruction, and in other factors that pertain to college training of engineers may be secured among the several branches of the engineering profession. To gain this end the Committee recommends that arrangements be made for holding a symposium on Engineering Education in 1922 in which representatives from all the National Engineering Societies should take part.

In a resume of the progress made during the year in the field represented by the Educational Committee much or little may be said. A statistical report on new buildings, improved equipment, enrollment and graduation data, and the numerous changes in courses and curricula, would no doubt be extensive, as much progress has been made in these respects; but this information, even if available, would probably be of little interest. The large increase in enrollment has made it necessary for most engineering schools to bend every effort towards meeting the increased demands for equipment and larger teaching staffs to the exclusion of all other interests.

The excellent record made by engineering graduates in the World War is by many taken as prima facie evidence that the training given these men must have been highly satisfactory and that a return to pre-war conditions would leave little more to be desired. In any event, the methods of giving instruction and the training given to engineering students now do not differ greatly from what obtained before the war.

The most noteworthy movement in technical education during the past year, is the extension of plans to greatly increase investigational work and industrial research in engineering colleges. The quickening power of research, the discovery and the development of new principles and new applications, is of more vital importance to educational institutions than to industrial organizations. Effective cooperation on a comprehensive scale, between the research divisions of manufacturing companies and the faculties of engineering colleges, is a consummation devoutly to be desired.

As forerunners of greater things to come the Technology Plan of the Massachusetts Institute of Technology and the Research Department, recently established at the University of Michigan, are of general interest. A better understanding of the problems involved and the solutions effected seems highly desirable. To this end the Committee has requested Dr. C. L. Norton, Director of Industrial Cooperation and Research to prepare a paper on the development of the "Technology Plan" for publication in the JOURNAL. Plans are under consideration for similar cooperative research departments or extension of engineering experiment stations in a number of Universities and technical schools.

C. EDWARD MAGNUSSON, *Chairman.*

INDUSTRIAL AND DOMESTIC POWER COMMITTEE

To the Board of Directors:

The Industrial and Domestic Power Committee during the present term has actively continued its plan of specific study and report on the application of electric power to industry. In the work it has had the help of eleven subcommittes, each headed by a member of the Industrial and Domestic Power Committee as follows:

No. 1—Subcommittee on Motors with Particular Reference to Speed Torque Characteristics. A. C. Lanier, Chairman.

No. 2—Subcommittee on Domestic Power Application. H. Weichsel, Chairman.

No. 3—Subcommittee on Applications in Printing Industry. W. C. Kalb, Chairman.

No. 4—Subcommittee on Cranes and Hoists. R. H. McLain, Chairman.

No. 5—Subcommittee on Applications to Machine Tools. H. D. James, Chairman.

No. 6—Subcommittee on Applications to Passenger and Freight Elevators. H. P. Reed, Chairman.

No. 7—Subcommittee on Applications in the Textile Industry. H. W. Cope, Chairman.

No. 8—Subcommittee on Applications in the Cement Industry. Fraser Jeffery, Chairman.

No. 9—Subcommittee on Applications to Pumps, Fans and Blowers. P. H. Adams, Chairman.

No. 10—Subcommittee on Applications of Electrical Energy in Industrial Heating. M. J. McHenry, Chairman.

No. 11—Subcommittee on Rubber Industry. W. E. Date, Chairman.

A complete roster of the several subcommittees will be found in the Year Book. These subcommittees have worked. Give them and their chairmen the full credit for our work of this term.

The Committee has conducted one Institute meeting at Akron and Cleveland on January 14th, 1921, and under the auspices of Subcommittee No. 11, W. E. Date, Chairman. It was a good practical meeting, with plenty of interest.

We have had one thorough committee meeting, *viz:* on January 14, 1921, at Akron, Ohio, with an attendance of 21.

I recommend that our committee plan and activities be continued another term. I feel that while our apparent results are not large, that nevertheless a constantly widening group in the Institute is becoming familiar with what we are doing and is taking interest in it. With patience and encouragement the plan will continue to grow in interest and value.

As a portion of this report is submitted a report of progress in the Industry prepared by Mr. W. C. Yates of our Committee and also a full report from the Chairman of each Subcommittee. I recommend these several reports for your careful consideration.

As a committee we have tried hard to make our work of value. It is of value. The work that individuals and groups of two or three have put in with resulting monographs are notable contributions to the Institute files and as Chairman of this Committee, I can do no less than direct attention to them.

I also commend to you the help and efficiency constantly accorded us in our work by the Secretary of the Institute, and those associated with him.

A. G. PIERCE, *Chairman.*

Industrial and Domestic Power Applications—Progress of the Art During the Year 1920

By W. C. YATES

Despite the fact that industrial activity slumped decisively during the latter part of the year 1920, the first three quarters of the year compensated for this to such a degree that the sum total of the industrial and domestic electrical equipment installed during the year was unquestionably greater than in previous years.

The use of electrically-driven domestic machinery, such as washing machines, vacuum cleaners, etc., showed an unprecedented growth until the business depression set in. An astonishing amount of such machinery was installed for the benefit of thousands of housewives, and this was especially true of washing machines. All this required no special developments in the way of motors, switching devices, etc., because suitable types of such electrical equipment were already available.

Turning to the industrial field in general, it may be said that considerable advance was registered in the incorporation of safety features in both motor and and control appliances, especially to the latter. The use of 50-deg. motors as compared to the old 40-deg. ratings increased and there was evidence of much more accurate study of the power required to drive machinery and a closer selection of the motors to do the work. This necessitated in turn the evolution of more overload protective devices, in which connection considerable improvement was made during the year.

In certain fields of industry no particular advance in the art occurred during the year 1920 to be particularly worthy of mentioning. In other fields definite steps in advance were made of which the following are worthy of note:

Mining. The activity in mining was not quite up to that of former years, but a number of interesting large equipments and an unusually large number of small hoist motors from 100 to 250 h. p. were installed or under construction at the close of the year. The McKinney Steel Company's hoist at Bessemer, Michigan, was put into commission. This is the largest d-c. iron ore hoist in the United States. It is driven by a 1650-h. p. 80-rev. per min. direct-connected motor.

Steel Mill. A record was made in the number of electric main roll drives put into commission. Improvement was shown in the accuracy of the speed control provided.

Considerable improvement was made in the control devices, especially of the magnetic type for steel mill auxiliary machinery, this improvement having to do with the better wearing qualities of the contactors and consequent longer life of the control equipment.

Machine Tools. In this field the development of motors and controllers for high-speed woodworking machinery stands out most prominently. This application required specially designed motors operated at frequencies as high as 300 cycles.

Textile Industry. An interesting development involved the application of individual drive to a series of tentering machines for starching and drying cloth where three independent rolls, each driven by an individual motor, were tied together by an automatic control equipment that insured the same speed of the fabric through the three machines. This same tie in of two or three machines to run at the same speed was accomplished in the printing of cloth and did away with expensive line shaft equipment very apt to get out of order.

Paper Mill. A new form of sectionalized motor drive for paper machines was developed, each section being driven by an independent motor, the speed of which

with relation to the speed of the other sections may be regulated to suit the requirements, and when once adjusted will retain this relationship as positively as though geared together.

A typical installation of this new drive was to a paper machine consisting of nine sections and employed in the manufacture of newsprint. This machine is designed for high-speed operation, producing paper 164 inches wide at the rate of 1000 ft. per minute. Eight sections of the paper machine are each equipped with a 100-h. p. 136-rev. per min. shunt-wound motor direct coupled, while the reel is driven by a direct-coupled motor of 30 h. p. These nine motors are supplied with power on a Ward Leonard system from a 600 kw. 250-volt turbine generator, and the speed of the machine as a whole is controlled by the voltage of this generator, the fields of the motor being excited from the same excitation source as the generator. The motors have the same speed regulation from no-load to full load.

The novel feature of the installation consists of 20-h. p. synchronous motors, one of which is mounted on the base of each of the d-c. motors, and is connected to the main motor by means of a gear and a pair of cones belted together with an eight-inch double-ply belt. The function of these synchronous motors is to rigidly tie together the various sections of the paper machine and maintain a positive unvarying speed relation between them.

Oil Well. The demand for oil well motors continued to increase in both old and new oil fields. The power companies were unable to supply ample power for this purpose.

In Los Angeles County the deepest electrically drilled oil well in the world was completed in June and its depth was 4650 ft., this being the "Anita A" well of the Shell Company of California.

Another development of the year in Southern California oil fields was the application of motor drive to deep drilling by the rotary method. This has progressed to a stage which gives every indication of its complete success.

Handling of Coal, Ore, etc. Improvements may be noted in the machines developed to handle coal, ore, and other bulk materials, although this involved no new developments in the electrical apparatus. A particularly interesting installation is the coal loading pier of the Baltimore & Ohio Railroad Company at Curtis Bay, Md. This was improved last year by the addition of four trimming machines. It is now possible to load a 10,000-ton boat in eight hours.

Elevators. Mention may be made here of the application of the two-speed a-c. motor to elevator service, the motor having two windings and the lower speed being employed for making landings.

Pumps and Fans. Particularly worthy of note is the increased use of synchronous motors in the operation of pumps and fans.

Logging. A unique installation which will undoubtedly have considerable influence on the future of the lumbering industry consists of a combined outfit of electrically-operated yarder and loader hoists which was placed in service in August, 1920, by the Snoqualmie Falls Lumber Company of Snoqualmie, Washington. The yarder is operated by a 200-h. p. 600-rev. per min., three-phase, 60-cycle, 550-volt motor of special construction designed particularly for the very high torque which is essential in yarder service.

The loader, which lifts the logs brought in by the yarder, is a duplex outfit with two hoists, each gear-driven by a 75-h. p. slip-ring motor. These hoists are not provided with mechanical brakes, but each has two electrical brakes, one being the standard type and the other a solenoid load brake which has inherent graduated braking characteristics. The reason for this double brake equipment is to secure low and fully controlled lowering speeds when placing the heavy logs on the cars.

Electric Shovels. Considerable improvement was made in the application of electric drive to shovels. The chief improvement involved the use of the Ward Leonard system in the individual drive of the several motions of the equipment.

Advance was made in the design and application of equipment for arc welding, electric furnace work and in other fields. A report of this kind cannot possibly cover the ground in any detail as it is only intended to point out the steady advancement of the art in the broad field of industrial and domestic power.

[This report to the Board of Directors was supplemented by a statement from each of the sub-committee chairmen, giving an outline of the plans and the work accomplished to date of each of the sub-committees.]

TELEGRAPHY AND TELEPHONY COMMITTEE

To the Board of Directors:

The following report contains a review of the engineering of Telegraphy, Telephony and Radio Communication during the Institute year 1920-1921.

Wire Communication along Railroads

Technical developments of the past year have placed the telegraph and telephone departments of railroads in the United States and Canada in a more serviceable condition than they have heretofore been. The work of the technical committees of the Telegraph and Telephone Section of the American Railway Association has been added to by the institution of committees handling the subjects of telephone transmission, radio and wired radio communication, and technical education for employees. A considerable number of new undertakings are now about ready for service trial in the field. Improvements are embodied in recommendations submitted by committees working

on the problems of protection against lightning disturbances, inductive interference, electrolysis, wire transpositions and stronger pole line construction.

The Railroad Administration's trunk circuits radiating from Washington, D. C., were promptly discontinued at the termination of Federal control of the railroads, and the wires returned to the control and use of the individual railroads. The general interchange of wire service between the various roads, through connecting railroads not concerned in the purpose of the communication, was at the same time discontinued.

The employment of recent types of telephone repeaters has been arranged for by a number of the large railroads for the purpose of improving long distance telephone service. On the New York, New Haven and Hartford Railroad the installation was completed of an aerial cable between New York and New Haven. Circuits in this cable have telephone repeaters, and on some pairs loading coils are provided.

The subject of stronger pole lines has been given serious attention on many railroads. On some lines the factor-of-safety plan of construction has been extended.

During the year the increase in telephone lines has not been great, due mainly to retrenchment following temporary business depression.

Some progress has been made in replacing older types of calling selectors, and changing the method of operation of others in order to obtain low-resistance simplexes for telegraph service. Also, some tests have been made with wire-guided carrier-current signaling in conjunction with engineers of the United States Signal Corps under the direction of Major General Squier, Chief Signal Officer.

The practise of welding joints in exposed lines has been extended.

Printing Telegraph Systems

The application of automatic printing telegraph systems to commercial requirements is being extended, both in the United States and Canada. A noticeable tendency is the gradual standardization of apparatus and of methods. Development generally is along the line of reducing equipment maintenance costs by simplifying the various printer units and making them more substantial mechanically.

For trunk circuits carrying heavy traffic the multiplex system is being widely applied. A multiplex system provides two or more two-way channels per wire. The ease with which the multiplex system may be made to meet traffic growth—simply by the addition of operating tables and associated equipment—is one reason for its success. Another reason is that it allows taking full advantage of the signaling capacity of a wire. With the multiplex it is possible to handle eight hundred or more messages per hour over a single conductor; correct incidental errors instantly, and have every message so handled ready for delivery to the addressee as soon as it has passed over the wire. An objection to older automatic systems was the time required in preparing the message for delivery after its receipt. There was also delay in correcting incidental errors.

A new field being entered by printing telegraphs is that including private branch offices, and way-office circuits. Developments in this direction center on the problem of producing a tape-printing machine so dependable as to require only occasional attention from mechanics, and so simple in operation as to be handled satisfactorily by an ordinary typist. A promising use for this system is its employment by commercial concerns and industrial establishments for intercommunion purposes and for communication between business offices and telegraph offices.

"Start-Stop" Printing Telegraph Systems

In all modern printing telegraph systems the principle of synchronism is employed. Systems employing continuous synchronism require that the apparatus at the transmitting and receiving stations be in phase at all times, and usually consist of distributors having constantly rotating arms operating in unison. Continuous synchronism is generally used when more than one simultaneous transmission over one wire is desired.

Systems not employing continuous synchronism, but providing instead that a signal be transmitted to start from a position of rest the arms of the transmitting and receiving distributors or their equivalents, are called "Start-stop" systems. The arms of the transmitting and receiving distributors are timed to rotate at practically the same speed for one revolution and then come to rest—one rotation for each letter, figure or other character.

The start-stop systems of recent American development use the five-unit signaling code. For circuits where the traffic requirements are such as to call for a speed of sixty words per minute, start-stop systems are satisfactory and their use is being extended. Such circuits are operated duplex over distances of 300 miles without intermediate repeaters. The employment of repeaters permits operation over greater distances.

Start-stop systems may be grouped into two classes. In the first, the distributor, transmitter and printer are separate units. With systems of this class a speed of approximately sixty-five words per minute is possible. In the second class, the distributor, transmitter and printer are self-contained in a single unit, the transmitter being controlled by a typewriter form of keyboard. Systems of the second class are also known as simplex printers and are operated at a speed of about fifty words per minute.

Submarine Telegraph Signaling

From the year 1858 until 1871 submarine cables were operated in one direction at a time only. Since the

latter year, cables have been operated duplex. From 1871 until 1908, important improvements were made in existing apparatus. In the latter year "magnifiers" were introduced which permit operation of long cables with considerably reduced line current strength, with consequent increase of signaling speed—50 per cent or more above previous speeds.

In recent years a tendency in cable signaling has been to introduce terminal apparatus aiming at reduction in operating costs. Tape perforators of the mallet type have been replaced by perforators having keyboards similar to those of a typewriter, permitting largely increased output per operator in a given time. Automatic transmitters are used which insure continuous transmission of uniform signals. Automatic relays have been installed to connect together sections of cables to permit direct working without the necessity of manual relaying of messages. In some cases instead of direct automatic relaying a re-perforator is introduced which is actuated by signals from one section of cable perforating a tape which feeds into a transmitter sending into an adjoining section of cable.

Considerable progress has been made in applying printing telegraph systems to submarine cables. Experimental installations have been in actual service operation during the past year or two. The application of printing telegraph systems to ocean cables reduces operating costs and, perhaps to some extent, increases operating speeds. Further improvements now being made in ocean cable printing apparatus will result in much simplified equipment with promise of an increased output in unit time.

Protection of Lines Against Lightning Disturbances

No radical changes have recently been made in the character of protection installed on communication lines for protection against lightning disturbances, but the growing need for continuous operation of lines has renewed interest in developing efficient self-restoring lightning arresters. Some of the more dependable existing types of arresters have been improved with the object of bettering the protection and lessening circuit interruption after static charges have been dissipated. Present types of arresters embody the principles of the airgap, vacuum gap, and choke coil.

Reduction of Inductive Interference

Promising progress has been made during the year toward the solution of the problem of inductive interference control and reduction. The growing difficulties in keeping communication and power circuits in well separated locations—attendant upon the rapidly increasing demands for these services—has brought a real appreciation of the need for thorough and systematic attention to the coordination of the engineering of these facilities.

As a consequence, increasing effort is being directed toward learning sound methods of coordination, and toward the application of these methods in the initial planning of construction. Prominent among these efforts toward more systematic treatment of the problem are facilities inaugurated by the National Electric Light Association for centralized study by a committee and engineering staff specializing in this subject.

It is an indication of sound progress that the problem is now recognized as of mutual concern by the various electric utilities. The trend is clearly toward cooperative study and treatment as in the best interests of these utilities.

Noteworthy in this direction is a step taken by the American Telephone and Telegraph Company and the National Electric Light Association in developing broadly laid plans for cooperative procedure in working out and applying methods for the control and reduction of inductive interference with telephone service.

So far as the committee has learned there has been no outstanding development during the year in the form of specific devices or methods applicable to either the communication or power facilities for inductive interference reduction. It is, however, of interest to note that the engineers of the American Telephone and Telegraph Company have developed and given some preliminary field use to a new type of noise meter," designed to measure the degree of disturbance indicated in a telephone receiver without bringing in the personal factor of the observer in judging equivalent noise as is the case with the older "noise" standard employed by the telephone companies.

Automatic Telephony

During the year there was in general a continuation of refinement in the design of automatic telephone apparatus. So far as radically new deve opments are concerned no epoch-marking inventions have been disclosed.

Further progress has been made in standardization of apparatus and in details of maintenance and operation. The undertaking to standardize nomenclature resulted in the publication of about 100 definitions of current terms.

There have been placed in service three devices the introduction of which may have an important relation to the further development of the art:

1. The call indicator, used in calling from an automatic office to a manual office during the period of mixed working, which displays the call number before the operator and permits automatic subscribers to dial all numbers.

2. A calling device number plate with office names in addition to numbers, to permit retention of office names in small multi-office exchanges converted to automatic.

3. A calling device number plate with the alphabet in addition to the numerals to enable the first few

letters of the office name to be used as numerals in a large multi-office exchange.

Carrier-Current Telephony and Telegraphy

At the Midwinter Convention of the Institute there was presented a paper on "Carrier-Current Telephony and Telegraphy," by two members of the committee, Messrs. Colpitts and Blackwell, which gives a history of this art; states the fundamental principles which underlie it; discusses the action of open-wire lines and short lengths of cable to the frequencies used in carrier operation, and describes the carrier systems which have been developed and put into commercial use in the Bell Telephone system. The historical part of this paper is interesting, showing the principles underlying carrier-current operation as having been worked out at an early date, but that economical use of such systems was not possible until the introduction of the three-electrode vacuum tube as a modulator, demodulator and amplifier; until the art of transmission over wires, including repeater operation, had been developed to its present state, and until the development of electric filters had been carried to the point permitting effective utilization of comparatively low carrier frequencies.

The commercial telephone installations described give four added telephone circuits over each pair of line wires in addition to the usual telephone and telegraph facilities provided by the wires. Commercial telegraph systems provide as many as ten added duplex telegraph circuits, also in addition to the usual facilities.

As pointed out in the paper, the apparatus involved in such systems is necessarily complex and, therefore, expensive, so that systems of this type are in general economical only for comparatively long circuits.

Radio Telegraphy

Radio communication during the past year has undergone a reorganization of ownership of the important patent rights which should relieve a very complicated situation and result in placing in use equipment superior to that heretofore employed. The radio companies are now in a position to proceed without imminent fear of infringement of essential patent rights.

The superior serviceability of continuous waves, with beats reception, has been recognized and the principle is being extended in practise.

The ease with which short waves can now be controlled from electron tubes has had much to do with the rapid change in the practise of the art. Spark transmitter systems, for all but ship emergency uses, are no longer planned for commercial operations.

With the more general use of continuous wave systems and the resulting greater possibilities of selectivity there is a strong legislative sentiment in favor of more liberal regulations. The use, with continuous waves, of a large number of working wave-bands, with a reserved emergency and calling band, will do much to eliminate the interference and troublesome delay which now exists at each of the several important ocean harbors. The sentiment that favors greater freedom in wave-band selection also favors the enforcement of more rigid requirements of purity of radiation and the securing of minimum damping at transmitting stations.

Transoceanic service has been further improved with a resulting increase in the volume of traffic handled and in the quality of service rendered. The gradual elimination of minor defects that commercial operation has brought to light has resulted in pronounced improvement in continuous operation over long distances.

The accomplishments in static elimination, permitting the better utilization of means of amplification of signals, have done much to overcome operating variations due to atmospheric disturbances and other causes.

A broadening of the field is noticeable in adapting radio systems and methods to new uses, and several such applications are looked for in the immediate future. The remote control of switches by means of radio is now being considered.

The superheterodyne method of reception, due to E. H. Armstrong, stands out as an important contribution of the past year.

Radio Telephony

The progress of radio telephony during the past year has been in the direction of the application of the three electrode tube, developed during the past seven years, to a point where it serves as an amplifier delivering comparatively large power, or as a reliable detector or telephone repeater, to the problem of supplying radio service of a commercial character in connection with existing wire.lines.

This progress in all its phases is illustrated in a radio telephone toll circuit now in commercial operation in the territory of the Pacific Telephone and Telegraph Company, furnishing telephone service between the Island of Santa Catalina and the wire network of the mainland centering in California.

The Avalon-Los Angeles radio toll circuit is believed to be the first radio telephone installation in the world to be opened for public service. The service was inaugurated on July 16, 1920. The radio circuit is operated according to wire line methods. The operating circuit is from Los Angeles, Cal., to Avalon on Catalina Island. The radio section is between two coastal stations thirty-two miles apart. The circuit is provided with through line ringing of a type which is free from interference, and a superposed telegraph circuit capable of forming a link in a duplex wire telegraph circuit. The transmission and quality over the circuit are of such high standards that it is regularly connected, when required, into the long distance telephone circuits. On several occasions conversations have been carried on between the S. S. *Gloucester* in

the Atlantic Ocean, and the Avalon office in the Pacific Ocean, the transcontinental telephone wire line being used as the connecting link overland.

The extensive application of types of electric wave filters in transmitting and receiving circuits has made it possible to obtain a good quality of speech and at the same time to secure greater selectivity than was possible with the prior art. The use of loops for receiving and of shorter wave lengths for short distances had to some extent reduced interference.

Standardization of Terminology

A sub-committee of the Standards Committee of the Institute has been engaged in the work of formulating standard definitions of terms most commonly used in telegraphy, telephony and radio signaling. The importance of such work, especially in the case of an art developing as rapidly as is the art of electric communication, is obvious. Not only is it of advantage to eliminate ambiguous and superfluous terms, and terms wrongly used or etymologically incorrect, although these may have come into extensive use, but it is especially important to select the most logical and appropriate terminology called for by the development of the allied arts so as to get a proper start and thus, in a large degree, avoid the necessity for later revision, and perhaps at a time when incorrect terms have been widely adopted in operating practise.

The terms so far chosen and defined have been simply and unequivocally, though broadly, defined in the light of a comprehensive survey of the field to which they are appropriate, thus eliminating the necessity of a multiplicity of terms covering slightly different applications.

Consideration also has been given to bringing about agreement so far as practicable between English speaking countries. In quite a number of instances the same term is given different meanings, or different terms are employed to convey the same meaning. The sub-committee on Telegraphy, Telephony and Radio is, therefore, cooperating with a corresponding committee of the British Engineering Standards Association, with the above mentioned object in view.

The Bell and independent telephone interests have found it mutually advantageous to unify not only operating methods, but also operating phraseology, for the purpose of facilitating the handling of interconnecting traffic involving cooperation between two groups of operators. This supplies an excellent illustration of the value of standardization as applied to terminology which can promptly be translated into dollars and cents.

Education in Communication Engineering

Considerably greater attention is now given in American universities and technological schools to instruction and research work in communication engineering. Sheffield Scientific School, Yale University, has an organized course in this field as has the Massachusetts Institute of Technology, and Columbia University, New York, has a course in submarine cable engineering. The College of the City of New York has a thoroughly equipped and organized communication laboratory, and at a number of the United States Army Departmental headquarters, or in their vicinities, thoroughly organized and equipped schools are maintained which cover these subjects.

In addition, the programs announced for the rapid introduction of automatic or machine switching in telephony, and the continued development of machine telegraphy will necessitate the instruction of large numbers of present employees of the operating companies, as well as recruits, who will be required to install, supervise and maintain the equipment. In this connection it is recognized that it is especially desirable speedily to perfect the terminology and thus to make available a common language for teaching purposes as well as for field use.

There is a noticeable drawing together of the engineers of the arts of telegraphy, telephony and radio signaling. The communication engineer of the immediate future will have to be well versed in the engineering of the three divisions of the general subject.

There are approximately six hundred communication engineers identified with the Institute, and the number is now increasing at the rate of about forty applications per month.

This report has been made up to include contributions forwarded by the following members of the Telegraphy and Telephony Committee: O. B. Blackwell, R. E. Chetwood, E. H. Colpitts, Charles E. Davies, H.W. Drake, S. M. Kintner, Stanley Rhoads, A. E. Silver, Arthur Bessey Smith and F. A. Wolff.

Donald McNicol, *Chairman.*

POWER STATIONS COMMITTEE

To the Board of Directors:

The work of the Power Stations Committee during the past year has included the routine work in connection with the analysis of papers bearing on power station subjects, which were referred to the committee for attention. In addition, the committee arranged for the presentation at the March meeting of the Institute of a paper entitled *Developments in Conversion Apparatus for Edison Systems*, by T. F. Barton and T. T. Hambleton. The committee also considered the suggestions of last year's committee, and gave considerable thought to the preparation of a symposium on auxiliaries in steam and hydroelectric plants. While a certain amount of work has already been done on this subject, because of the limited amount of time available, further action has been postponed,—the recommendation of this committee being that the incoming committee continue the work which has been started with a view to presenting a symposium on this subject during the early part of the coming year.

In accordance with the request of the Board of Directors, your Committee presents in this report a brief outline of the progress of the art and the most important developments in power station work during the past year. There is also included an appendix, which is an abstract of the bibliography of the important articles treating of power station design and operation appearing recently in American and foreign technical journals.

During the past year, there have been several notable power station developments which have recently been placed in service, or are now in course of construction. These plants are of large size and incorporate many new and interesting features of design, particularly in the details of plant layout and the combination and application of auxiliary equipment.

Among the recent installations may be mentioned the Colfax power station in Pittsburgh, the Hell Gate Station in New York City, the Delaware station in Philadelphia, and the Calumet station in Chicago.

The Colfax power station represents the latest development in the so-called "mouth-of-mine" plant. This type of plant is of especial interest at this time, in view of the trend toward interconnection. It is essentially a design of the type most suited to bulk generation and distribution of power.

The Hell Gate, Delaware and Calumet stations are designed particularly for metropolitan service where a relatively large number of feeders at generator voltage are provided for the distribution of power. In the design of these plants, however, particularly the Hell Gate and Calumet stations, certain marked changes have been made in the general arrangement of busses and high-tension switching equipment.

In the use of auxiliaries, there is to be noted a decided trend toward electric drive. Two of the outstanding features in this development are the application of 2300-volt motors in sizes of 100 h. p. and over, and the use of differential relay protection of the various motor circuits. Considerable attention has been given also to the layout and protection of all auxiliary circuits as well as improvements in the motors and control equipment to insure continuity of service. These features are of vital importance in the modern power station. The increase in the use of electric power for auxiliary drive has been relatively large and involves a number of problems which were not considered of prime importance when the size of the electric installation for auxiliaries was comparatively small.

It is further recognized that conditions in power station service are different from the usual industrial plant, and it is to be noted that the development of present control equipment, which heretofore has been based largely on the experience gained in industrial service, is now being given the attention required for power plant service, where the necessity for continuous operation over long periods requires greater liberality in details of design than has heretofore been considered necessary.

Turbine Generator Units

The past year marks a number of improvements in details of design and construction of turbines. A more careful selection of material, closer inspection and improved testing facilities, particularly in connection with static and dynamic balancing of rotating parts, have had an important bearing on increased reliability and economy of operation.

There was also evidenced a definite change in attitude toward the use of larger generating units. The records of the past year show no increase in the size of single-cylinder steam turbine units, the largest unit of this type being of 45,000 kw. capacity. In two of the largest stations under construction in 1920 and 1921, the generating units have been 30,000 and 35,000 kw., respectively. There are, however, now in operation, a number of 40,000- and 60,000-kw. cross-compound units, consisting of two or three 20,000-kw. generators, which show satisfactory performance in point of continuity of operation and overall efficiencies.

In 1920, the two manufacturing companies engaged in building large turbo-generators, took contracts for 23 units of 20,000 kv-a. capacity, and larger. These 23 units aggregated 800,000 kv-a. and 690,000 kw., the average size unit being 35,000 kv-a. and 30,000 kw. It is interesting to note, in this connection, that of the 23 large units purchased in 1920 only five were for 25-cycle operation, and these units were purchased for installation in New York City.

In large hydraulic installations, the 90,000-kw. development at Niagara Falls, placed in operation in 1920, and the 350,000-kw. plant of the Hydro-Electric Power Commission of Ontario are noteworthy for their large capacity and new features of layout and installation. The No. 3 Station extension of the Niagara Falls Power Company is notable in delivering better than 90 per cent of the available energy of the water to the generator terminals. It is also of interest to note that the 45,000 kv-a. generators and turbines now under construction for the Hydro-Electric Power Commission, will, when completed, be the largest hydroelectric units thus far placed in operation.

Closed Air Ventilating Systems

A comparatively recent development in turbo-generator cooling is the closed air circulating system, in which a definite volume of air is circulated continuously. There is a closed air path consisting of the generator and short connecting ducts to some device for removing the heat from the air. This cooling device may be the familiar spray washer, analogous to a jet condenser; or the hot air may be passed over tubes through which cold water is circulated, analogous to the surface condenser. Some installations of the closed air system with water tube coolers have been completed in England, and several trial installations have been projected in this country. There are a few installations of the closed air system in operation in this country, using the spray cooler.

The principal advantages claimed for the closed air system are effective elimination of dirt from the generator and reduced fire risk. The water-tube cooler has the additional advantage of eliminating all danger of water or ice entering the generator. There have been a few winding failures from this cause in this country, and apparently a considerable number of such failures in England, which, according to information received, accounts for the more active development of the water-tube cooler abroad. Whether these advantages of the closed air system will compensate for the obvious disadvantages of increased complication and congestion in the station layout and the appreciable increase in cost (in the case of the water-tube cooler), only further study and experience can determine.

Large Power Transformers for Station Use

Single-phase transformers of a capacity of 23,600 kv-a., 60 cycles—larger than any heretofore constructed—have been supplied during the past year for stepping up from generator voltage to a present transmission voltage of 66,000 volts and an ultimate of 132,000. A bank of three single-phase transformers takes care of the entire output of a 60,000-kw., 11,500-volt, turbo-generator unit. The transformers are connected in delta on the low voltage side, and star on the high voltage side. Each transformer weighs 126,000 lb., requires a floor space of 11 ft., 3 in. by 10 ft. 3 in., and measures 23 feet from the rail to the tip of the high voltage bushing.

The largest single-phase, 25-cycle, transformers ever built are being constructed for the new Queenston-Chippewa project of the Hydro-Electric Power Commission of Ontario. These transformers are of the shell type; are rated at 15,000 kv-a., and are arranged to step up in banks of three from a 45,000 kv-a. water-wheel generator to a present transmission voltage of 110,000, and ultimate voltage of 132,000. Transformers are connected in delta on the low-tension side, and star on the high-tension side. Each transformer weighs 186,000 lb., requires a floor space of 11 ft. 6 in. by 10 ft. 6 in., and measures 28 ft. 2 in. from the rail to the tip of the high voltage bushing.

For a number of years the maximum voltage for commercial transmission remained stationary at about 150,000 volts, but during 1920 this was raised to 165,000 volts, and transformers are under construction for operation on a 220,000-volt, 60-cycle system now being built. Core type transformers of 16,667 kv-a. and 8,333 kv-a. are being built, arranged for 11,000 volts on the low-voltage side, and 127,000 volts on the high-voltage side, so that three transformers may be connected in star for 220,000 volts.

These transformers are designed for grounded Y service and are equipped with one high-voltage bushing, the other end of the winding being permanently grounded to the tank to form the grounded neutral.

The windings of the 16,667 kv-a. transformers are so arranged that the 220,000-volt line lead is at the center of the column of coils, hence the potential to ground decreases towards the ends of the column, so that the coils nearest the yokes of the core are at or near ground potential. These transformers weigh 158,000 lb., require a floor space of 14 ft. 5 in. by 11 ft. 8 in., and measure 22 ft. 9 in. from the rail to the tip of the high-voltage bushing.

Among the large air-blast transformers produced were five 4550 kv-a., 10,900 Y/210-volt units for use with synchronous converters for the d-c. system of the New York Edison Company. These transformers are of high inherent reactance and are used in conjunction with the synchronous converters without the use of synchronous boosters to obtain the necessary range in continuous voltage, this voltage range being secured through the compounding characteristics of the synchronous converter in conjunction with the transformer reactance.

The operating reports during the year demonstrate the value and the greatly extended use of the oil conservator on large and high-voltage transformers. The utility of this feature is becoming more definitely established by the protection afforded from condensation of water in the transformer oil, the elimination of possible gas explosions due to decomposition of the oil and the gases so produced mixing with air at the top of the tank, and to the practical elimination of sludging of the oil due to oxidation when in contact with air at fairly high temperatures.

Switching Equipment

In general, it may be said that there is a decided tendency toward simplification in station layouts and details of design. Complicated switching connections to take care of possible contingencies have been replaced by simpler layouts, resulting in reduced costs and marked reduction in operating troubles. Particular care is evidenced in switch-house layouts in the provision for safeguarding against serious trouble in case of switch explosions or oil fires. It has been recognized as advisable to provide as far as possible for greater space and greater accessibility to all parts of the electrical equipment using oil.

The semi-outdoor type of construction which has been adopted by the Niagara Falls Power Company at their Echota substation, is the most recent example of a departure from the standard type of switch-house construction designed for the purpose of preventing as far as possible the danger from oil explosions. The switches in this case are erected in structures in such a way that the operating mechanisms are covered, but there is no enclosure in front of the oil switch pots so that the force of any explosion which might occur is not in any way confined.

Bus Construction

Considerable attention has been given to the recent designs of switch house and equipment. Increased

station capacities with the possibility of increased short-circuit stresses, call for a more substantial type of construction than has heretofore been considered necessary. One installation on record incorporates a type of bus support designed to satisfactorily take care of short-circuit stresses of 10,000 lb. applied at right angles to the top of the support. Greater attention is also being given to the layout of conductors, the avoiding of loops in the circuit wherever possible, and the provision for increased space between conductors so as to minimize the effects of magnetic stresses. In the new station of the Hydro-Electric Power Commission of Canada, at Queenston, the busses are arranged horizontally instead of the usual vertical arrangement, and are mounted on five-foot centers on the floor with concrete barriers between phases.

A radical departure in the arrangement of busses and switch-house connections is incorporated in the designs of the new Calumet Station of the Commonwealth Edison Company, Chicago, and the Hell Gate Station of the New York Edison Company. The principle adopted in these stations is to separate the phases of each circuit, putting them into what practically amounts to separate rooms, thereby eliminating the possibility of flash-overs, oil switch explosions, or other troubles resulting in short circuits due to the close proximity of all three phases. This layout has involved the design of new switch-operating gear so that the pots of each phase of an oil switch may be operated simultaneously from a single operating mechanism.

Oil Circuit Breakers

The most important development in oil circuit breakers has been in the extremely heavy-duty type. The latest designs are for units having a rupturing capacity approximately twice that of any previous breakers constructed, or 58,000 arc-amperes at 15,000 volts. This has necessitated designing the circuit breaker structure of sufficient strength to withstand shock and internal pressures in excess of any previously encountered. It has also required a design of the conducting details that will withstand the heavy magnetic stresses resulting from heavy short-circuit currents encountered only in the largest systems.

For substation and auxiliary power service, there is a trend toward the truck type of circuit breaker. The designs that are being constructed are fully protected by interlocking features to guard the safety of the operators.

Paralleling the high-voltage developments in transformer design, there has been a corresponding advance in oil circuit breakers for 220,000-volt service for heavy interrupting duty. These breakers are physically the largest ever constructed, the tanks being 8 ft. 6 in. inside diameter, and 11 ft. high. The height to the top of the terminal bushing is 20 ft. For a three-pole unit, a floor space of 10 ft. by 30 ft. is required.

Reactors

Developments are still under way in the design and application of reactors, particularly as affecting certain mechanical features which have not given highly satisfactory results in operation. These changes have been made, and for present service conditions, the performance of this type of equipment can be considered fairly reliable.

A phase of the subject which is being appreciated more today than heretofore is the necessity for guarding against the introduction of too high a reactance in the tie-line connections between stations or large systems. Too low a reactance on large systems, particularly, will result in excessive energy transfer at time of trouble; and, on the other hand, too high a reactance will result in decreased synchronizing power, with the resulting operating complications at times of system disturbance. The subject of synchronizing power between stations as influenced by characteristics of equipment and tie-lines, prime movers and excitation, is one which warrants the most careful consideration.

Disconnecting Switches

The design of disconnectors is undergoing the same improvement as has occurred in other bus and switching connections. The danger of the loaded disconnectors being opened is being removed by the very general use of pilot lights connected to the corresponding oil switches and by mechanical interlocking of the disconnectors with the oil switches. In the case of the new Calumet Station in Chicago, the disconnectors will actually be operated simultaneously with the oil switch by mechanical interconnection so arranged that the disconnector opens immediately after the opening of the oil switch and the disconnectors close immediately before the closing of the oil switch. In some stations, the interlocking is arranged on the doors in front of the disconnectors, thus safeguarding against the opening of the switch before the corresponding oil switch has been opened. The rather frequent mistake of operating the wrong set of three disconnectors has been taken care of in some cases by a system of links and levers which operate all three disconnectors, or, in some cases, even six disconnectors, by the manipulation of a single lever which then may be locked in the open position if necessary.

Operating Instructions

Several companies have, during the last few years, prepared detailed operating instructions for their operating and maintenance attendants, covering the operation of transmission and station equipment. The value of such instruction lies in replacing the word-of-mouth transmission of operating experience through a constantly changing operating personnel. Carefully-prepared, written instructions make it possible for operating attendants to be transferred to different

watches and to work in different groups without the necessity of the men getting used to each other's peculiarities of operating procedure. It facilitates the rapid breaking in of new men and makes the methods of operation more independent of personnel. The preparation of such instructions entails a large amount of painstaking labor, but in the opinion of those who have done so, is entirely justified by the results obtained.

H. P. LIVERSIDGE, *Chairman.*

APPENDIX A

Important Articles on Power Station Design and Operation that have Appeared in American and Foreign Technical Journals

A — STATION DESIGN, OPERATION AND COSTS

"Efficient Operation of Central Power Stations," by J. D. Morgan. *Power*, October 7, 1919. This article presents data and curves dealing with the operation of every unit and of the station as a whole and the systematic testing of all units to detect the falling off in efficiency and the exact cost of operation in the various departments of the plant.

"Development of Automatic Hydroelectric Generating Stations," by T. A. E. Belt. *Electrical World*, February 28, 1920. The author deals with the automatic operation and remote control especially applicable to small and medium sized developments and the use of synchronous and induction generators for this service.

"Power House Foundation," by E. M. Lurie. *Power Plant Engineering*, February 1, 1920. Information is given on methods for testing soil, column footings, drainage and other construction problems in securing permanency of foundation.

"Automatic Hydroelectric Stations," by T. A. E. Belt. *Electrical World*, April 10, 1920. Details are given covering the operation of the automatic hydroelectric generating station of the Iowa Railway and Light Company at Cedar Rapids, Iowa and the remotely controlled hydroelectric generating station of the Ontario Power Company of Ontario, California. Details of a proposed automatic system are given which will tie into a tranmission system which is fed by two very large steam driven generators.

"Water Station of the Southern Power Company," by W. S. Lee and Richard Pfaehler. *Electrical World*, May 8, 1920. Details and construction are given for a 90,000 h. p. generating station and outdoor switching station (the largest of company's system) designed to provide for operation under extreme conditions of floods of large magnitude.

"Data on Output and Load Factor of Largest Generating System in America." *Electrical World*, May 8, 1920. For all lighting, power and electric railway companies in the United States and Canada operating generating stations with outputs in excess of 100,000 kw-hr., the following data are tabulated for the years, 1917, 1918, and 1919: Peak load, date of peak load, yearly output, yearly load factor.

"Steam-Electric Generation in Far West," by W. F. Durand and C. H. Delany. *Electrical World*, May 15, 1920. Present tendencies in the design of generating stations on the Pacific Coast are outlined from the standpoint of fuel consumed, operation with hydroelectric systems, and the size of generating station required. Automatic control is also discussed.

"Importance of Control and Signalling Circuits in a Power Station," by Probst. *Elektrotechniche Zeitschrift*, January 29, 1920. The author emphasizes the importance of clearness and neatness in mounting all auxiliary conductors and shows on photographs and tracings some examples of the *A E G* back of panel wiring system.

"Stabilizing Large Generating Systems. *Electrical World*, July 3, 1920. Abstract of features brought out by Dr. C. P. Steinmetz and R. F. Schuchardt in papers presented before the American Institute of Electrical Engineers. Operating conditions in the three large power houses of the Commonwealth Edison Company are outlined, giving an analysis of cable failures and the use of reactors. Conclusions drawn by Dr. Steinmetz regarding the use of power limiting reactors, and locating them in the system are given.

"Water Power Plant at Gösgen, Switzerland." *Schweizerische Bauzeitung*, January to May, 1920. Details are given of hydraulic construction with numerous illustrations. The development is located on the Aare at Gösgen, Switzerland and has a total rating of 45,000 h. p.

"Hydroelectric Power Station at the Great Lake, Tasmania." London *Engineer*, July 9, 1920. An interesting scheme of speed control of water wheels is described for which it is claimed the advantages of both needle and deflector regulation are secured.

"Pelton Wheel Reconstruction," by Percy Pitman. London *Engineering*, June 25, 1920. Structural changes in Pelton water wheels are described, first, to replace defective and broken buckets which were becoming a source of danger and, second, to economize water by putting on buckets of a more modern and efficient type. It is reported that the efficiency was improved about 5 per cent by these changes.

"Niagara Falls 100,000-H. P. Development," by John L. Harper. *Electrical World*, September 18, 1920. Details of the general engineering problems involved are given, together with comments by N. R. Gibson in hydraulic design and efficiency of units in plant, comments by L. S. Berin Bernstein of effect of loading on construction of substructures and main features of plant operation by George R. Shepard.

"Centralizing Power Plant Maintenance," by W. C. D. Eglin and F. C. Ralston. *Electrical World*, September, 25, 1920. The author points out that by separating maintenance of plant equipment from operation uniform standards of work can be established and a group of repair specialists developed. The plan of handling maintenance work in centralized shops is shown in organization charts listing the personnel of the maintenance sections and showing their relations to the other groups comprising a station operation division. The system outlined is used in maintenance work in the generating stations of the Philadelphia Electric Company.

"Analyzing Maintenance Costs." *Electrical World*, September 25, 1920. This article shows the relationships of the age of equipment to energy output and shows that electrical apparatus is far less expensive to repair than steam equipment. Data are also given showing total repairs to be virtually proportional to plant rating. Maintenance costs of steam plant equipment for 1918 to 1920 in a station having a rating varying from 43,000 kv-a. to 63,000 kv-a. are given.

"High Economy in Small Steam Plants," by E. H. Tenney. *Electrical World*, September 25, 1920. The author gives results of experience in operating 28 plants containing one to three boilers. The causes of low efficiency are reviewed and means suggested for preventing, detecting and correcting operating conditions.

"Springdale Station of West Penn Power Company," by G. G. Bell. *Electrical World*, September 25, 1920. Details are given of the design of a steam plant with an ultimate rating of 300,000 kw. The station is located at a coal mine and coal is delivered to the bunkers direct from a mine tipple. Part 2 of this article describes electrical and operating features.

"Developments in Power Plants and Generating Stations," by Alfred Still. *Electrical Review*, August 21, 1920. The author gives general tendencies in power station design, both hydroelectric and steam electric.

"Electrical Features of Niagara Falls Power Station," by J. Allen Johnson. *Electrical World*, October 23, 1920. The

author points out that to insure reliability of service and simplicity of operation each 32,500-kv-a. generator in the Niagara Falls 100,000 h. p. Extension has been dealt with as a separate unit. Features of control are outlined.

"Power Station Designs." *Beama*, August, 1920. This subject is discussed under the following division: Drive of auxiliaries, maintenance of efficiency, condensing plant, feed water system, guarantees and testing, and over-all thermal efficiency of power station.

"Dalmarnock Power Station." London *Electrician*, September 20, 1920. This is a new power plant erected on the River Clyde not far from Glasgow. The ultimate capacity is 150,000 h. p. Energy is stepped up and transmitted at 20,000 volts to substations over three-core split conductors and six-core type cables using the Merz-Hunter system of protection.

"Design of the New Canadian Niagara Power Project." *Engineering News-Record*, October 14, 1920. The article gives fundamentals which govern the design of the hydroelectric installation of the Queenston Chippewa hydroelectric plant of the Hydroelectric Power Commission of Ontario.

"Electrical Equipment of the Super-Power Station at Golpa, Germany," by H. Probst, *Elektrotechnische Zeitschrift*, September 2, 1920. The output of this station was intended to be used for nitrogen fixation and to supply large nitric acid plants in the neighborhood with approximately 250,000,000 kw. hr. or one-third of the total output. The plant is located close to a lignite mine and is laid out for 64 steam boilers feeding eight A. E. G. turbines each coupled to one 6000-volt 50-cycle 22,000-kv-a. generator.

"Electrical Features of Springdale Plant of West Penn Power Company," by George S. Humphrey, *Electrical World*, December 4, 1920. The author describes the considerations in laying out this station to be operated at high power factor and the use of temperature detectors in generators and transformers, flexible scheme of supply for auxiliaries and balanced relay protection. Part 2 of this article (*Electrical World*, December 11, 1920) dealt with physical arrangement of equipment, balanced relays to protect generators and transformers and methods to indicate total station loads.

"Interconnection of Power Systems," by Harold W. Smith, *Electrical Journal*, November, 1920. The author deals with the important considerations in planning for interconnection of power systems and covers the following points: Selection of switching equipment, tie lines having ample synchronizing power to hold the systems in parallel; relay protection system; voltage conditions with regard to the flow of reactive current.

"Safety-First Methods of a Big Power Plant," *Power*, April 19, 1921. Rules for protecting employes of the United Electric Light & Power Company, New York City against mechanical and electrical dangers.

"Coal Handling Methods at New Baltimore Station," *Electrical World*, Jan. 15 and 29, 1921. Details of how coal is received and handled in a 140,000-kw. station and the method of dividing the load with large hydroelectric plant. Generator fire protection and the welding of steam piping.

"Switchgear in Modern Power Station," by R. A. R. Bolton, *English Electric Journal*, October, 1920. Arrangement of circuits and typical connections with comments on the use of current limiting reactors to reduce effects of short-circuit currents.

"Australian Steam Station of 125,000-Kw. Rating," *Electrical World*, Feb. 19, 1921. Design of a plant located in coal field where coal can be secured at cost of 50 cents per ton. All electrical equipment located out of doors.

"Hydroelectric Station of 50,000-Kw. Rating Built in 15 Months," by R. C. Starr, *Electrical World*, Feb. 26 and March 19, 1921. Construction and design for Kerckhoff station of San Joaquin Light and Power Corporation at Fresno, Cal. Considerations that influenced layout of equipment.

"Development of 450,000 Kv-a. on Pit River in California," by A. H. Markwart, *Electrical World*, March 12, 1921. Plans for construction of five stations utilizing 2070 ft. drop in Pit River. Units of 35,000 kv-a. rating to serve 220,000-volt transmission line.

"50,000-H. P. Waterwheels for 500,000-H. P. Plant," by E. T. J. Brandon, *Electrical World*, March 20, 1921. Layout of equipment for Queenston-Chippewa station of Hydro-Electric Power Commission of Ontario employing 50,000-h. p. turbines under a head of 305 ft.

"Colfax Station at Mouth of Coal Mine," *Electrical World*, April 2 and 16, 1921; *Power*, April 5, May 3, and May 24, 1921. Features of Duquesne Light Company's Colfax station design incorporated to attain high economy and reliability of operation. Details of initial installation of 60,000 kw. for a plant of 300,000 ultimate rating. Three-element compound 60,000-kw. turbo generators are installed and provided for. Duplication of circuits and equipment and arrangements to prevent spreading of troubles that may occur.

"New Type of Switch House to Prevent Bus Short Circuits," by B. C. Jamieson, *Electrical World*, April 2, 1921. Arrangement of New Calumet station of Commonwealth Edison Company with details of wide separation of bus phases to preclude interphase short circuits. Use of current limiting reactors to exclude outside disturbances.

"Plants of Chilean Exploration Company," by M. Neustatter, *Elektrotechnische Zeitschrift*, Jan. 6, 13, and 20, 1921. Detailed illustrated article on station layout and equipment built by Siemens-Schuckert in Berlin for producing electrolytic pure copper from ores in Chile. Power station is rated at 40,000 kv-a. Four 12,500-kw. steam turbines drive 9000-kw., 0.9-power factor, 5000-volt, 50-cycle, 1500-rev. per min. generators and receive steam from 16 B & W oil fired boilers. Descriptions of station electrical layout and transformer station are given, with wiring diagrams.

"Output of Systems Exceeding 100,000,000-Kw-Hr. in 1920," *Electrical World*, April 23, 1921. Peak load, date of peak and output for years 1920, 1919, 1918 and 1917 of 71 central station systems and 9 electric railway companies. Also tabulation of energy generated and purchased and that used for light, power and railways.

"Delaware Station of Philadelphia Electric Company," *Electrical World*, May 21, 1921. Factors taken into consideration in laying out a 180,000 kw. station on limited space at a time when steel was difficult to procure. Among the mechanical features discussed are the coal and ash handling facilities, unusual furnace design, facilities for converting to oil or powdered coal operation and the selection of auxiliaries.

B — Prime Movers and Generator Design and Operation

"Designs of Large Vertical Alternating-Current Waterwheel-Driven Generators," by M. C. Olson, *General Electric Review*, November, 1919. The author calls attention to some of the special features that must be considered in the mechanical and electrical design of large hydroelectric generators.

"Spring Thrust Bearing and Cooling Coils on Larger Vertical Generators," by T. W. Gordon, *General Electric Review*, November, 1919. The author states that for many years one of the limiting features of large vertical machines was the need of a simple thrust bearing.

"Features of Design in Large Hydraulic Turbine," by F. H. Rogers, *General Electric Review*, November, 1919. The author analyzes problems encountered in designing wheels of high efficiency for both low and high head applications. He calls attention to conditions under which certain losses become sufficiently important to warrant considerable effort to minimize them.

"Failures of Turbo Generators and Suggestions for Improvement," by J. Shephard, London *Electrician*, January 16 and 23, 1920. In the opinion of the author failures may be roughly

classified under (1) mechanical weakness, (2) electrical weakness, (3) heating and fire risks, (4) ventilating difficulties. An analysis of these failures is presented.

"Alternators Rated at 22,000 Kv-a. for Glomfjord," by J. Wennerberg, *Teknisk Tidskrift Elektroteknik*, November, 1919. This article gives drawings and pictures of two large three-phase generators built for the Norwegian Government's plant at Glomfjord, Sweden. These are rated at 20,000 kv-a. with a continuous overload capacity of 22,000 kv-a. and are the largest water turbine driven generators built in Europe.

"Effects of Short Circuits on Power House Equipment," by E. G. Merrick, *General Electric Review*, November, 1919. The author deals particularly with the electromagnetic stresses and abnormal temperatures developed in power house equipment resulting from short circuits.

"Mechanical Design of Large Turbo Generators," by M. A, Savage, *General Electric Review*, February, 1920. The author deals with high speeds and increased stresses in the construction of rotors and the ventilation of the modern turbo generator.

"Optimist's View of Turbine Development," by Richard H. Rice, *Electrical World*, April 17, 1920. Abstract of an address by Mr. Rice before the Boston section of the A. I. E. E. and A. S. M. E. in which he showed that turbine troubles were due chiefly to manufacturing conditions during the war.

"Ventilation of Steam Turbine Generators," by George Monson, London *Electricity*, March 12, 1920. The article reviews the development of forced air ventilation for cooling large generators and describes the modern closed air circuit with humidifying equipment and air dryers under the generator foundation.

"Short-Circuit tests on a 10,000-kw. Turbine Alternator," by E. S. Henningsen, *General Electric Review*, March, 1920. Data are given covering a series of tests on the performance of alternators having smooth-core rotors under short circuit.

"Huge Induction Regulator Installation," by Raymond Bailey, *Electrical World*, June 12, 1920. The author points out that in order to work transmission lines at maximum load the Philadelphia Electric Company has installed out-of-doors two 1750-kv-a., three-phase regulators and gives the conditions under which they operate. He presents a chart which shows how transmission line characteristics were determined.

"Electric Drive for Station Auxiliaries," by E. E. George, *Electrical World*, June 12, 1920. The author takes up the advantages of electric auxiliaries and the economies that accompany those advantages.

"Heating of Alternators and Induction Motors," by M. Baringolz, *L'Industrie Electrique*, November 25, December 10, and 25, 1919. The author presents a set of formulas permitting the calculation of the working temperature of stator copper, rotor iron and rotor copper in alternators and induction motors.

"Increasing Oil Circuit Breaker Capacity," by C. J. Hejja, *Electrical World*, July 10, 1920. The author gives details of a study on a standard oil circuit breaker with a view of determining the extent to which the rupturing capacity at short circuit of switching units in present use may be increased in order to avoid, if possible, the expense of replacing them by units of larger capacity or of a different type. A breaker equipped with pressure vents, hollow contact rods and improved liquid for quenching the arch showed greatly increased rupturing capacity under test.

"Predetermination of the General Dimensions of Electrical Machinery," by H. de Pistoye, *Revue Generale del'Electricite*, January 24, 1920. This article contains a number of general theorems regarding the relations between output and certain general dimensions, such as rotor diameter, iron legnth, width of air gap, speed, etc. A general formula is derived which shows the most economical relation of diameter to axial length for rotating machinery.

"Grounding of Electric Machinery and Installations," by J. Damien, *Revue Generale del'Electricite*, January 24, 1920. The author cites the French rules regarding grounding of electrical installations and criticizes their vagueness in wording. Advantages and disadvantages of different methods of grounding are discussed and some practical suggestions given.

"Governor Adjustment for Efficient Parallel Operation," by F. Oppenheimer, *Electrical World*, July 31, 1920. The author presents speed load curves of prime movers with various governor adjustments and gives details of the method used in adjusting the governors in the plant of the Pennsylvania Water and Power Company.

"Present Tendencies in Turbo Alternator Design," by J. Shepherd, London *Electrician*, July 2, 1920. The writer deals particularly with the problem of ventilating and water-cooling of turbo alternators. He also takes up the proper insulating of coils and the danger to coils of vibration.

"Selection of Oil Circuit Breakers," by W. A. Coates, London *Electrician*, July 2, 1920. The writer discusses the rating of oil circuit breakers with reference to breaker capacity as defined by the British Engineering Standards Association. He points out the advantage in having graphic methods of determining short circuit current values in networks and shows a chart devised for such use.

"Temperatures in Large Alternating-Current Generators," by W. J. Foster, *General Electric Review*, July, 1920. The author calls attention to certain advantages that would be derived in taking the air directly from the room and passing it away to some point in the building remote from the machines or out of doors.

"Features of 37,500-H. P. Water Turbine," *Electrical World*, October 2, 1920. In this article comments are presented by W. M. White on water wheel and generator considered as a homogeneous unit in the 100,000-h. p. extension to the plant of the Niagara Falls Power Company. Louis F. Moody discusses the design of waterwheels for generators of different makes.

"Factors Determining Generator Design," *Electrical World*, October 16, 1920. Comments by F. D. Newbury on the design of generators used in the new extension of the Niagara Falls Power Company together with comments by R. B. Williamson and W. J. Foster on designs furnished by the Allis Chalmers Company and the General Electric Company respectively.

"Repair and Inspection of Hydraulic Turbines," by L. W. Wyss, *Electrical World*, November 27, 1920. Practical information is given on taking machines out of service together with points to be observed during inspection.

"Oil Switches for Large Electrical Power Systems," London *Engineer*, September 3, 1920. Short-circuit characteristics of alternators and speed of oil switch opening with units of extremely large size are discussed in this paper.

"Continental Switch Gears," by W. A. Coates, *Beama*, October, 1920. The author deals with circuit breakers and electrical layout common to European practise.

"Recent Development in Turbo Alternators," by F. D. Newbury, *Electrical World*, January 17, 1920. The author comments on the increase in ratings from 1913 to 1917 and the tendency in steam turbine-generator construction and operation.

"Investigation of Water-Air Radiators for Cooling Generators and Motors," by H. G. Reist and E. H. Freiburghouse, *General Electric Review*, February, 1920. The authors point out that in the case of electrically driven ships the usual method of washing the ventilating air for turbo-generator units cannot be applied on account of the space limitations on shipboard. The plan of circulating salt water through a radiator much on the order of the automobile radiator and cooling the hot ventilating air by this means, has been investigated by the authors. A number of data and curves is given to show the advantages of this method where space is limited.

"Present Status of Large Turbo Generators," by Dr. Louis Bell, *Electrical World*, January 17, 1920. The author deals

with the size of station and the requirements from the standpoint of economy and simplicity in station design and operation. The speed stresses are touched upon and the advantages and disadvantages of multiple-stage generating units.

"Some Recent Developments in Large Steam Turbine Practise," by K. Baumann, April 7, 1921, *Journal* Institution of Electrical Engineers, London. The author reviews in great detail developments of steam turbine design and construction in Europe and America since 1912 to date and also deals with a new design which embodies a multi-exhaust system where the steam in the last stage passes partly into impulse blading and partly through reaction blading with claim of greater capacity and efficiency with no appreciable increase in over-all dimensions of single barrel turbines of the Curtis type.

"Temperature Limits of Large Alternators," by G. A. Juhlin. *London Electrician*, Jan. 28, 1921. The possibility of increasing temperature limits in alternators using class B insulation is discussed with list data for breakdown voltage of mica wrapped in copper bars after heating for 7000 hours at 190 deg. cent.

"The Modern Hydraulic Turbine," by Frank H. Rogers and Lewis F. Moody, *Journal of Philadelphia Engineers Club*, March, 1921. Two articles on the hydraulic turbine from standpoints of modern requirements; tests of models, special features of designs; and requirements of larger stations. Mr. Moody reviews the turbine's evolution and describes new types of high speed runners.

"Manufacture of High-Voltage Alternating-Current Windings," by W. Zederbohm. *Siemens Zeitschrift*. Illustrated description of high voltage motor, generator and regular windings developed during last 20 years. Asphalt treatment and inclosing of coils in sleeves of "Mikanite" standardized by Siemens-Schuchert Works.

"The Gas Turbine," London *Engineer*, Feb. 11, 1921. Tests at works of Thyssen & Company on 500-h. p. gas turbine invented by H. Holzwarth and built in 1914.

C — Boiler Plant Design and Operation

"What the Adoption of Higher Steam Pressure Will Mean," by F. R. Parsons. London *Electrician*, January 2, 1920. The writer considers the effect of higher steam pressures on standard boiler design, on the material used and on reciprocating engines.

"Extension to L Street Station, Boston," by Charles H. Bromley. *Power*, January 27, 1920. Boiler room provided for convenience and economy. 30,000-kw. single-cylinder impulse turbine installed.

"Electrically Heated Boilers and Heat Storage." London *Engineering*, February 6, 1920. Details are given for the heating of water by electricity where water power is inexpensive. Attention is called to tests on two electricity boilers in Switzerland in which it is said that 90 per cent efficiency was obtained. Several makes of boilers equipped for electrical heating (mostly of Swiss origin) are described.

"Sluicing Ashes Shows Low Cost," by A. W. Morgan. *Electrical World*, July 3, 1920. The method used in the new Denver station of the Denver Gas & Electric Light Company is explained, which shows the handling cost of 16.4 cents per ton of ashes or about 2 cents per ton of coal fired.

"Preparing Pittsburgh District Waters for Boilers." *Power Plant Engineering*, August 15, 1920. Reference is made to the water of the Monongahela River where water pumped from mines into the river is highly charged with sulphates and the industrial pickling and by-product coke plants which line the river banks have a contaminating refuse water which is discharged into it. Efficient testing and treating required for this water are described.

"Surface Condenser Maintenance," by R. J. T. Wood, *Electrical World*, September 25, 1920. The author shows by illustrations the composition and structure of tubes. He points out that many steam station troubles are directly traceable to salt-water leakage in condensers where plants are near the seashore and discusses the over-all plant economy when adequate condenser maintenance is not attended to. Reference is made to maintenance work in the plant of the Southern California Edison Company at Long Beach and Rodondo Beach.

"Steam Plant Metering Practise," by Robert E. Dillon. *Electrical World*., September 25, 1920. The author points out that the checking of losses in the boiler room and the turbine room of large central stations by the aid of records from instruments is passing through the stage today which was passed by the electrical end of the station years ago. He refers to the types of instruments and records which are essential to efficient steam plant operation.

"Emmet Mercury Boiler." *Power*, August 3, 1920. Details are given for the construction of a mercury boiler and turbine which has been developed by W. L. R. Emmet and makes use of high boiling point of mercury and its condensing points at 28 inches vacuum and 465 deg. fahr. The heat given out by the condensing mercury vapor makes steam of the cooling water and this steam may be used to drive another turbine or for any other purpose for which steam may be required. The experimental equipment has been in operation with over 1000 kw. load on an electric turbine and its operation showed that the economies predicted were fully realized. Mr. Emmet believes that with an increase of 15 per cent in the amount of fuel used the same amount of steam can be supplied to the turbines as under present conditions and a mercury turbine will generate power equal to about 66 per cent of the power generated by steam turbines.

"Factors in the Design of Large Boiler Plants," by J. G. Rollow. *Electrical Review*, August 21, 1920. The author discusses the principal factors affecting equipment of boiler plants of large capacity.

"Selection of Steam Plant Meters," by J. W. Andree. *Electrical World*, November 20, 1920. The author divides metering of apparatus into classes necessary for safe operation, for good operation, and for checking results and gives a list of devices included in each of these groups. He also shows that the proper use of correct meters will greatly improve economy. Reference is made to the results which are being secured in the Long Beach Steam Station of the Southern California Edison Company.

ELECTRICAL MACHINERY COMMITTEE

To the Board of Directors:

In its endeavor to assist in advancing the art in the field coming within its scope, and in recording progress made therein, the Committee on Electrical Machinery has cooperated with the Standards Committee, the Meetings and Papers Committee and the Library Board of the A. I. E. E.

For some time it has had under consideration certain proposed changes in the Standardization Rules relating to high-potential testing in order to overcome the failure of the present rules to impose any test between adjacent coils in any circuit of any phase; any test between phase windings where the highest potential difference exists when the machine is operating, and to overcome the unknown stresses imposed at certain points due to the capacity effects in large machines.

The Committee has reviewed for the Papers Committee all the papers submitted for presentation before the A. I. E. E., or for publication in the JOURNAL, that deal in any way with electrical machinery. Through the medium of papers solicited the Committee has aimed to place on record the advances in the art as indicated in design and theory as well as in the construction of the great power plants on sea and on land. It has arranged for the preparation and presentation of a paper by Mr. E. S. Henningson on "The Application of Synchronous Motors to the Propulsion of Cargo Boats"; a paper by Mr. John L. Harper on "Extension to Plant No. 3 at Niagara Falls," and one by Mr. William M. White on "Hydraulic Turbine Development." These three papers will be read at this Convention.

For the purpose of determining in what way the Engineering Societies Library now supplies the wants of the Electrical Machinery Committee, or of persons interested in electrical machinery, a study was made of the conditions in the Library from the point of view, not of librarians, but of persons desiring to obtain information concerning the theory, design, construction and operation of electrical and allied machinery. This study disclosed an unnecessarily unsatisfactory condition in the facilities placed at the disposal of engineers interested in, and under necessity for, investigating new phenomena and for solving new problems, and these facts have been laid before the Library Board of the A. I. E. E.

In the work undertaken by the Electrical Machinery Committee, the chairman has had the unanimous and enthusiastic support of the members of the Committee.

B. A. BEHREND, *Chairman.*

(*To be continued*)

Magnetic Properties of Compressed Powdered Iron

BY BUCKNER SPEED and G. W. ELMEN

Research Laboratories of the American Telephone & Telegraph Company and the Western Electric Company, Inc.,

This paper describes a new magnetic material which is peculiarly suited to the construction of cores in small inductance coils and transformers such as are used in a telephone plant. The requirements which were to be met involved a core material which should have a constant permeability, a small hysteresis loss, and a small eddy current loss within the range of magnetizing forces and frequencies which are met in telephonic operation. The material which was developed to meet these requirements is formed by fine grains of powdered iron, insulated and compressed. There are described the circumstances and experiments which led to this development and also the method of commercial production. Tables and curves are given showing the magnetic, electrical, and mechanical properties of the material.

THE DEVELOPMENT of a successful method of compressing insulated grains of iron to produce a material magnetically and electrically suited for use in the telephone plant has had a determining effect upon recent progress in methods of loading and compositing telephone lines as well as upon the introduction of carrier current systems of multiplex telephony. It is the purpose of the present paper to discuss briefly the circumstances and experiments which led to this development and to describe the method of commercial production and the magnetic characteristics of the finished material.

The most important use of this material is in the construction of the cores of the loading coils which are introduced at regular intervals to increase the inductance of a telephone circuit.[1] It is also used in the cores of inductance elements in filters for carrier current systems,[2] and in those of reactance coils and transformers for radio telephone circuits. Coils for use in these circuits have to meet requirements which are in general quite different from those of other circuits, as, for example, power transmission circuits.

In telephone-transmission lines, for example, the inductance of the loading coils must remain constant throughout the entire range of intensities of the currents which are employed in the telephone plant. The amplitude of the currents to which a given coil is subjected may vary as much as one hundredfold.

The first requirement for the magnetic core-material of a loading coil, therefore, is that its permeability shall remain constant over the range of magnetizing force corresponding to the normal range of telephone currents.

The second requirement arises from the simultaneous use of circuits for telephone and telegraph transmission. It is necessary that the variation in the effective resistance of the coil, which is caused by hysteresis[3] and occurs when two currents of different frequencies and amplitudes are superposed, shall be so small that what is known as "flutter" in the transmitted speech shall not be objectionable.

The third requirement concerns the effective resistance which is introduced into the telephone circuit because of hysteresis and eddy-current losses in the core-material of the loading coil. It is required that the effective resistance due to these causes shall be small in order that the total resistance of the coil, including its copper loss, shall be small as compared to the resistance of a length of line conductor equal to the length of the loading section. Since the effects of hysteresis and eddy currents will depend upon both the frequency and the amplitude of the telephone currents, it is further evident that the constancy of loading coil operation requires that these losses shall be minimized.

These requirements were met successfully in the early development of loading coils by the use of hard iron either in wire or in sheet form. Cores of hard-drawn wire were developed and adopted by the engineers of the American Telephone & Telegraph Company and were used successfully until the core-material herein described was put on a production basis. Two advantages pertain to the use of hard material in preference to soft. In the hard material the variation in permeability for a large range of magnetizing forces is less than in the soft iron. This is especially true at the initial part of the magnetization curve where, for a very large range of magnetizing force, the permeability of the hard material is constant. The second advantage is due to the fact that over this range in which the permeability is constant the hysteresis loss per unit of volume is less in the hard than it is in the soft material for the same flux density.

In order to take advantage of the constancy in permeability and the low hysteresis loss at small magnetizing forces[4], the coils were designed so that for the range of speech currents the magnetizing force corresponded to that of the initial part of the magnetization curve. In a standard design of coil the magnetizing force corresponding to an average telephone current of one milliampere is of the order of 0.01 gauss.

In addition to the magnetic requirements for the core-material, its electrical resistivity is also of great importance. This is due to the fact that the important frequency of the speech currents as usually assumed,

4. In this paper the term "small magnetizing force" is used to indicate forces below 0.1 gauss.

is approximately 800 cycles per second and unless the resistivity of the material is very high or the core material is very finely subdivided, the losses caused by the eddy currents are excessive. In order to reduce the effective resistance caused by these losses it was found necessary to employ iron wire drawn down to a diameter of 0.004 in. and, in addition, to insulate the separate convolutions of the contiguously-wound core. Two types of wire were established as standard for loading coils, classified according to the permeability at low magnetizing forces. For one type the permeability is 95, and for the other, 65. The difference in permeability between the two types is the result of a difference in the process of drawing the wire, that of lower permeability being drawn a greater number of passes without annealing.

Cores constructed in the above manner were used for a number of years. With the introduction of repeaters, and especially on composited and phantomed circuits, the requirements as to stability and constancy in the physical characteristics and operation of loading coils became more severe. To meet these conditions it was found necessary to introduce air gaps[5] at right angles to the flux path in the core of the loading coil. The introduction of such air gaps was conditioned by certain other requirements, specifically for example, by the requirement as to a balanced-winding arrangement in coils designed for phantom circuits where an absence of balance between the several windings would introduce stray magnetic fields. In telephone practise parallel circuits are loaded at a common point and the coils are either adjacent on a loading pole fixture, or are assembled in a common case. Under the latter condition, if stray magnetic fields surround the cores of such coils there would be introduced an interference between parallel telephone circuits which is ordinarily spoken of as "cross-talk." For this reason the air gaps which are introduced into the core of the loading coil have to be spaced symmetrically with respect to the balanced-winding arrangement.

The production of this hard-drawn wire requires the use of diamond dies and these were imported from Europe. Early during the war importation became impossible and our supply of hard-drawn wire was thus seriously curtailed. Fortunately the development of the powdered-iron cores while not completed had reached the stage where the material could be quickly put into commercial production to meet the demand for core material.

In order to be useful as a substitute for fine iron wire, a magnetic material must have the following general properties: (1) the permeability at low magnetizing forces must be between 20 and 100, (2) the material must be very finely divided in a direction at right angles to the magnetizing force in order to decrease the effective resistance caused by the eddy currents, (3) the hysteresis loss must be low, and (4) the cost of manufacture into core form must compare favorably with that of iron-wire cores.

From a preliminary investigation the most promising possibilities seemed to lie in the direction of using finely-divided iron powder, each particle sufficiently insulated to eliminate eddy currents between contiguous particles. The general idea of using this kind of material for telephone-magnet cores was old. In 1887 Heaviside[6] described cores made from finely divided iron and insulated with wax. Coils with such cores were tested on an inductance bridge at telephone frequencies for the purpose of determining to what extent the effective resistance caused by the eddy currents had been eliminated. The results indicated that the subdivision was very effective in eliminating eddy-current loss.

About the same time others[7], notably Fritts, suggested the use of finely divided iron for pole pieces and armatures in dynamos and motors and for the core of other electromagnets. Interest along this line then subsided, probably because more satisfactory results could be obtained with laminated iron.

About 1900 the interest in the use of finely divided iron for a core material was revived by the introduction of loading coils. For the cores of loading coils Dolezalek[8] suggested the use of finely divided iron in very much the same form as Heaviside had previously employed it for telephone magnets.

A constructive suggestion was made in 1901 by F. A. Pickernell of the Engineering Department of the American Telephone and Telegraph Company. He advocated the use of finely divided magnetic oxide of iron or iron powder as a suitable material for loading-coil cores. The possibility of using iron oxide was investigated by the Telephone Company engineers and actual methods of production [9] were developed and loading coils with cores of this material were constructed. Toroidal cores were made by using iron laminations or iron tape. After the cores were formed they were subjected to an oxidizing process which transformed the iron into magnetic oxide of iron (Fe_3O_4). The results obtained on these coils gave enough promise to indicate that it would be possible to produce cores in this way. As hard-drawn iron wire cores were developed about the same time and as the energy losses of these cores were considerably less the development work was discontinued.

The magnetic properties of finely divided iron have also been studied by a number of investigators[10] but all the permeabilities which they record are for values of magnetizing force much larger than those with

which we are concerned in telephony. In all of the investigations, with the exception of Benedicks[11], the material was either entirely uncompressed or was very slightly tamped. The permeabilities recorded by these experimenters are less than 10. Benedicks compressed his material by continued tamping, and the permeability of his core, at the magnetizing force of 143 gausses, was 90 as compared with a permeability of 143 for solid iron at the same magnetizing force. Benedicks, however, was interested only in direct-current magnetizations, and the material which he produced was of no value at high frequencies as the particles of iron were not insulated.

There was nothing in the literature to indicate what permeabilities could be obtained at low magnetizing forces. It seemed, however, to one of the authors[12] that the use of powdered iron for core-materials had important possibilities. He concluded that if a pure finely divided iron powder could be insulated with a very tenacious insulation and compressed so that the specific gravity was nearly that of solid iron, it should be possible at low flux densities to obtain permeabilities of the order required for loading-coil cores.

Experimental Work

The experimental work, through which powdered-iron cores of commercially valuable properties were first obtained, could not be fairly stated unless we here made acknowledgment of the able assistance rendered by J. T. Butterfield and J. H. White. To W. Fondiller is due the designing and engineering of the loading coils embodying the compressed iron cores.

Early Experiments. Our earliest efforts were directed towards obtaining particles of finely divided iron each with a coating which would retain its insulating properties when a mass of them was compressed to a specific gravity of the order of that of solid iron. The iron powder used in the early experiments was powder reduced from iron oxide in hydrogen. This powder was mixed with a little water and slowly dried by heating it to a temperature between 100 and 150 deg. cent. until the particles had a coating of oxide on them. This oxide was mostly red oxide of iron although under certain conditions both the red and black oxide were present. After the oxide coating was obtained, the powder was mixed with a thin solution of shellac and dried while the mass was stirred to prevent caking. When dried, the insulated powder was put in a mold and pressed into rings from 1/8 to 1/4 in. thick, and with inside and outside diameters of 2 1/8 and 3 7/8 in., respectively.

Pressures. The pressing was first done with a press which developed a pressure of 100,000 pounds per square inch of surface of the rings. As this pressure did not seem high enough to obtain the required permeabilities, a press was obtained which, for the same surface, produced pressures up to 250,000 pounds per square inch. When the material was subjected to 200,000 pounds per square inch of surface cores were formed which had sufficiently high insulation between the particles and also at low magnetizing-forces a permeability[13] between 50 and 60, that is of the order required by a substitute in loading coils for the 95-permeability wire.

Insulation of the Particles. In addition to the method of insulating the particles described above, a number of other methods were attempted before the one now used commercially was adopted. In place of oxidizing and shellacking, some cores were made in which shellac only was used. Others were insulated with asphaltum compound dissolved in carbon tetrachloride, and the mixture stirred until the solvent evaporated. A number of different kinds of varnishes were also tried. In place of oxidizing the surface of the iron particles, there was also tried the method of chemically producing on the surfaces coatings of other compounds of iron. None of these methods gave as satisfactory results as the method used in our early experiments. This was due to the fact that if the insulation were made sufficiently thick to prevent the iron grain from cutting through it under pressure, it introduced too large air gaps in the magnetic circuit.

While investigating these possibilities, J. C. Woodruff[14] discovered that when a quantity of iron powder was rolled in a zinc-lined drum for a few hours and then insulated with a shellac solution the resulting product showed for corresponding permeabilities a higher specific resistance than had been obtained by any of the previous methods. Pursuing this further he found that if before applying the shellac he mixed the iron powder with flaked zinc, rolled the mixture in a drum for a few hours, and then removed the zinc by sieving, a very thin and tough insulation of the grains of iron was obtained which did not break down when the cores were compressed. As this is a very convenient method of insulating the material commercially, it was adopted and is being used in commercial production of powdered iron cores.

Production of Iron Powder. Next to the question of the possibility of using iron powder for making cores, the problem of obtaining a source of supply is important. In the early experimental work, as has already been stated, there was used iron reduced from the magnetic oxide by hydrogen. The two main objections to this material were the high cost of production and the fact that the reduced iron was very soft The latter is a serious defect, as has already been

11. *Journal of the Iron and Steel Inst.* Vol. I, p. 407, 1914.

12. B. Speed, U. S. Patent No. 1274952, 1918.

13. In determining permeability no correction is made in the flux density for the insulation and the air space. The cross-sectional area is assumed to be the measured cross-sectional area of the ring, and the permeability recorded is the total flux divided by the cross-section of the ring and the magnetizing force.

14. U. S. Patent No. 1,292,206, 1919.

pointed out, in case the material is to be used for cores in the highest grade of loading coils. The pressing of the iron powder introduces a considerable amount of mechanical hardness but is insufficient to give the material as good magnetic qualities as the 65-permeability iron wire. The introduction of other means of hardening the material, although possible, would increase the cost of production. When studying the question of obtaining a source of supply, one of the authors[15] concluded that if iron was deposited from a suitable electrolyte it could probably be ground to the required fineness and it would also have the additional quality of being a hard material. This method of producing iron powder would also be relatively inexpensive and the quality of the material could be controlled a great deal more readily than in other methods of production. Work was immediately started to investigate this possibility and the preliminary work was so encouraging that a good-sized experimental plant was installed.

Satisfactory material was obtained by electrolysis of a solution containing ferrous sulphate and chloride and ammonium sulphate using anodes of mild steel and cathodes of polished sheet steel, with current densities of about twelve amperes per square foot. The cathodes were removed when the deposit had reached a thickness of 1/8 to 1/4 in., and washed in hot water to remove the electrolyte.

The deposited iron was then stripped from the cathode sheets and broken up into pieces about an inch square. This material was next placed in a ball mill and ground until all of the material would pass through a sieve with 80 meshes to the linear inch. The ground iron then contained particles from the largest size passing through the sieve to the very finest flour. Sieve analysis showed that approximately 35 per cent to 50 per cent of this material would pass through a 200-mesh sieve. Unless the iron powder was to be annealed, it was now ready for the insulating process.

If annealed iron was desired, the powder was packed into cast-iron boxes and heated to about 850 deg. cent. and then allowed to cool slowly with the furnace. The material was then removed from the boxes. Because of a certain amount of sintering it was necessary again to break up the material into the original mesh by putting it through a rock crusher. By this process the iron was very readily reduced to its original fineness. The annealing process also purified the iron to a certain extent since the occluded hydrogen was liberated at a comparatively low temperature and reduced to pure iron the oxide which was present. This made the annealed iron purer than the unannealed.

This method of obtaining the supply of iron powder has been adopted commercially and a description of the commercial plant will be given later in this paper.

15. G. W. Elmen, U. S. Patents No. 1297126 and 1297127, 1919.

Magnet Cores. The present method of producing magnet cores from iron powder is as follows: The iron is deposited electrolytically, ground, sieved, insulated and pressed in dies at a pressure of 200,000 pounds per square inch of surface. The rings are pressed to a thickness of approximately 1/4 in., the inside and outside diameters depending on the design of the coil. After pressing, these rings are baked at a temperature of 125 deg. cent. to remove the moisture. The cores are constructed from these rings. Ordinarily several of the rings are stacked together to make a core and covered with insulating tape before the copper winding is put on.

The use of iron powder of the kind described lends itself very readily to the construction of cores having any desired permeability below 60 at low magnetizing forces. At the present time three standard types of core-material are commercially produced. These will be designated, for convenient reference, as grade A, grade B, and grade C. The order of designation does not imply the order of superiority in magnetic properties. The same pressure, 200,000 pounds per square inch, is used for all of these grades. Grade A consists of annealed and insulated iron-powder which has passed through a sieve with 80 meshes to the linear inch.

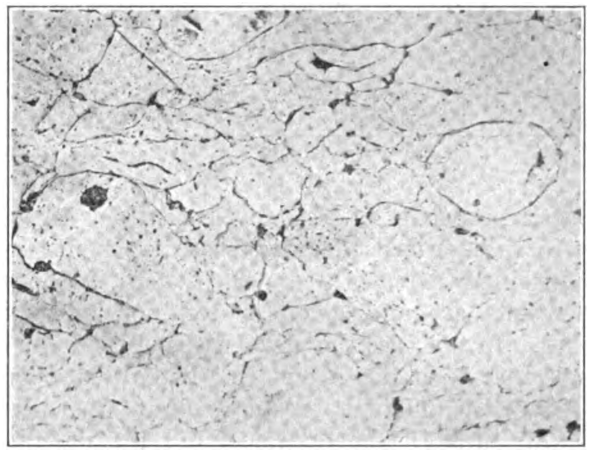

FIG. 1—MICROPHOTOGRAPH OF SURFACE OF GRADE A RING
Magneflcation 100 diam.

The permeability of this material at low flux densities is approximately 55. Grade B consists of material of the same mesh as grade A but is a mixture, 90 per cent unannealed and 10 per cent annealed. The permeability for the same magnetizing forces is approximately 35. Annealed iron is added in order to bring the permeability up to the desired value and also to add somewhat to the mechanical strength of the rings. Grade C is a mixture of the same proportions as grade B, but it passes through a sieve of 200 meshes per linear inch. The shellac insulation for grade C is also considerably heavier than for grades A and B. The permeability of grade C is approximately 25.

Fig. 1 is reproduced from a microphotograph of the surface of a grade A ring showing the distortion of

the iron grains and the thin walls of insulation separating them.

Figs. 2 and 3 show two sizes of rings and a coil in which part of the winding and core has been removed.

Electrical and Magnetic Properties

There will now be presented the results of tests under a large number of conditions, from which there may be obtained a very complete idea as to the electrical and

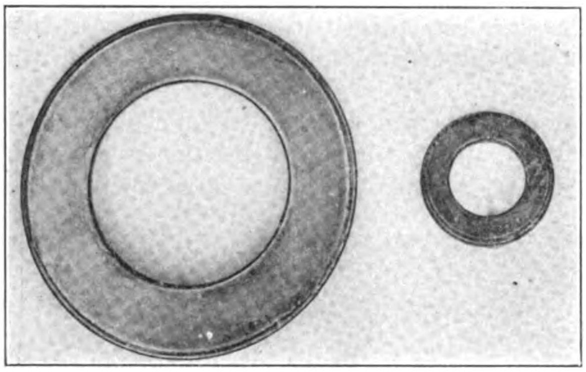

Fig. 2

magnetic properties of electrolytic iron powder. The tests to be described cover cores pressed from electrolytic iron-powder both annealed and unannealed. The results are also given of tests on uninsulated powder. In this case the powder was of the same fineness as that of grades A and B. There is also shown the effect of different pressures upon the physical constants of both the annealed and the unannealed iron-powder. The tables show also the specific gravity

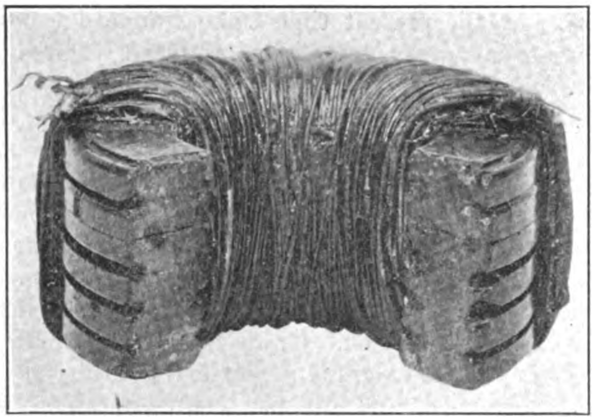

Fig. 3

and the tensile strength of some of the materials. It is to be noted that grades A, B and C are standard materials; the other materials for which values are given are recorded only for purposes of comparison.

Specific Gravity. The specific gravity for uninsulated iron powder, compressed with different pressures, is given in Fig. 4. The specific gravities for the grades A, B and C cores are given in Table I.

Tensile Strength. The mechanical strength of the rings is considerable and no difficulty is experienced in handling them in the general process of manufacturing cores. In Table I is recorded the load in pounds per square inch of cross-section necessary to disrupt the pressed rings under tension. The specific gravity of the rings is also given in this table.

TABLE I.

	Tensile Strength Pounds per sq. in.	Specific Gravity
Grade A rings	1375	7.1
Grade B rings	925	6.4
Grade C rings	375	6.0

Specific Resistance. In the measurement of specific resistance the current was led into core rings of the

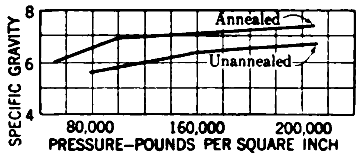

Fig. 4—Specific Gravity of Uninsulated Iron Powder Cores Compressed with Different Pressures

material by small clamps, placed diammetrically opposite one another, and thus dividing the ring into two equal current paths. The drop of potential was measured in different parts of the surfaces of the two halves of the ring. The clamps were then turned through 90 deg. and measurements were again made. The specific resistance of the compressed rings was calculated from the dimensions of the ring and the distance between the potential points. The specific resistance of the various types of iron powder use in these measurements are recorded in the same tables

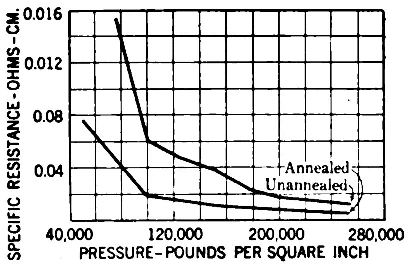

Fig. 5—Specific Resistance of Uninsulated Iron Powder Cores Compressed With Different Pressures

as the magnetic properties and in Fig. 5 is plotted the specific resistance for uninsulated powder compressed with different pressures.

Magnetic Properties. The magnetization curve and hysteresis loops for direct-current magnetization were measured with the ballistic galvanometer. From these measurements the permeability, the hysteresis loss (W_h), the hysteresis exponents (x), and the hysteresis coefficient (η) were computed. The data on various types of cores are tabulated in the following tables and in some instances are shown by typical graphs.

Tables II and III and Figs. 6, 7, 8, 9, 10 and 11 give the data on uninsulated iron powder cores, both annealed and unannealed, for various pressures.

Tables IV, V, VI give data on cores of grades A, B and C. The magnetization curves for these cores are plotted in Fig. 12.

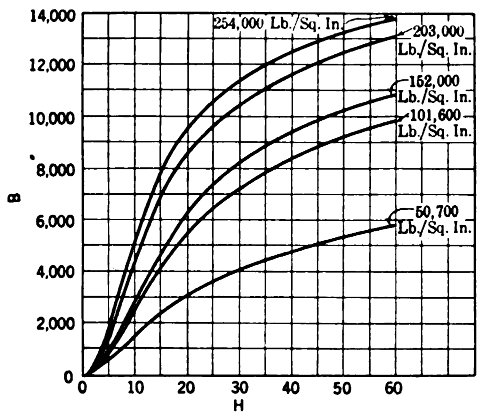

FIG. 6—MAGNETIZATION CURVES FOR ANNEALED UNINSULATED IRON POWDER COMPRESSED WITH DIFFERENT PRESSURES

DATA DERIVED FROM MEASUREMENTS OF INDUCTANCE AND EFFECTIVE RESISTANCE

Certain data as to magnetic constants are deducible from the values of inductance and effective resistance of coils especially wound on cores of the various materials. Measurements of inductance and effective resistance were made with an inductance bridge. Measurements were made for frequencies, within the audible range, of values 500, 800, 1200, 1600 and 2000 cycles per second. In all these bridge measurements the flux density of the cores was low. The measuring current was obtained from a vacuum tube oscillator which gave a sinusoidal wave. The test coils were so constructed that for the highest frequency of measuring current the energy losses in the copper winding caused by eddy currents, and also the dielectric losses

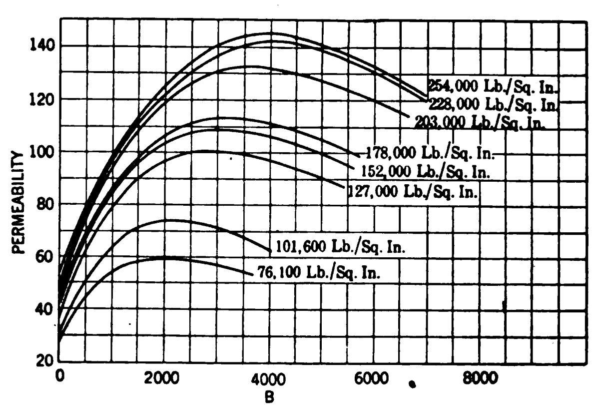

FIG. 9—PERMEABILITY CURVES FOR UNANNEALED UNINSULATED IRON POWDER COMPRESSED WITH DIFFERENT PRESSURES

were very small compared to the iron losses. These losses, were therefore, negligible and did not enter into the computation of hysteresis and eddy-current losses in the cores themselves.

From measurements of the effective resistance and inductance of the test coils there was derived the permeability of the core-material, and also the components, due to eddy currents and hysteresis respectively, of the iron losses in the core. The equations whereby these calculations were made are given below. Preceding them there is a statement of the symbols which are employed in the equations.

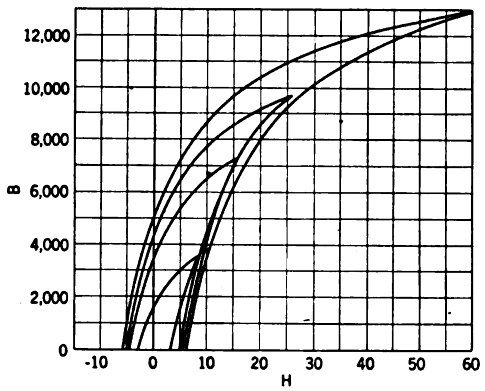

Fig. 10—Hysteresis Characteristics for Annealed Uninsulated Iron Powder Cores Compressed With a Pressure of 203,000 Lb. Per Sq. In.

The permeability of the core material was computed by equation (3). The effective resistance corresponding to the iron losses was separated into its components by equation (7), which is derived from Steinmetz's equation (1). Instead of expressing the power loss in the iron per cubic centimeter, it is more satisfactory for purposes of coil design to express the effective resistance per henry of inductance.

The transformation of the usual Steinmetz equation to the form which we have found convenient is indicated by equations (1) to (8) inclusive and the accompanying text.

L = inductance in henrys
I = current in amperes (r. m. s.)
W = power expended in ergs in the core
H = magnetizing force in gauss
B = flux density in gauss
μ = permeability

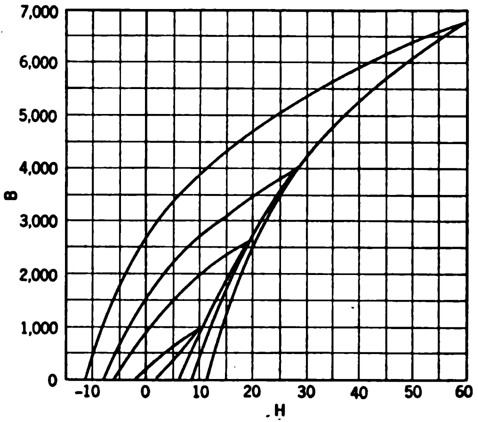

Fig. 11—Hysteresis Characteristics for Unannealed Insulated Iron Powder Cores Compressed With a Pressure of 203,000 Lb. Per Sq. In.

N = total number of turns of winding on the core
A = cross-section of core in cm².
v = volume of core in cm³.
l = mean length of the magnetic circuit in cm.
R_t = effective resistance in ohms caused by the iron losses. This is equal to the measured resistance at a designated frequency minus the direct-current resistance.
R_h = effective resistance caused by hysteresis loss
R_e = effective resistance caused by eddy current loss
x = hysteresis exponent

	0.0380	1	26.3			0.0000070	2.401	0.00000699	"

η = hysteresis coefficient

γ = eddy current coefficient

f = frequency in cycles per second

$$W = \eta\, v\, f\, B^x + \gamma\, v\, f^2 B^2 \qquad (1)$$

$$W = R_t\, I^2 \times 10^7 \qquad (2)$$

$$L = \frac{4\,\pi\, N^2 A\, \mu}{l \times 10^9} \qquad (3)$$

$$H = \frac{4\pi\, N\, I\, \sqrt{2}}{l \times 10} \qquad (4)$$

$$v = l\, A \qquad (5)$$

From (1) and (2)

$$R_t\, I^2 \times 10^7 = \eta\, f\, v\, B^x + \gamma\, f^2\, v\, B^2 \qquad (6)$$

Eliminating I^2 and v from this equation by means of (3), (4) and (5), gives

$$\frac{R_t}{L} = 8\pi\, \eta\, f\, \mu\, B^{x-2} + 8\pi\, \mu\, \gamma\, f^2 \qquad (7)$$

Equation (7) gives the effective resistance caused by the energy losses in the core in ohms per henry. The first member on the right-hand side of the equation is the effective resistance caused by the hysteresis loss and the second that caused by the eddy current loss.

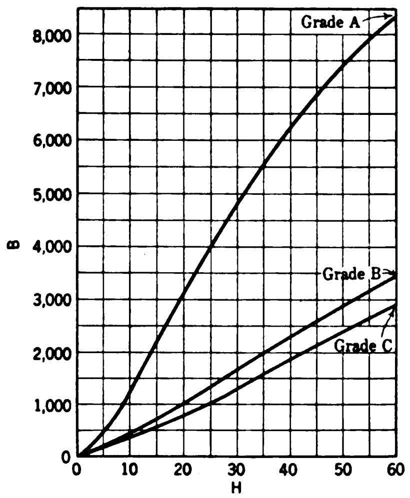

FIG. 12—MAGNETIZATION CURVES FOR GRADES A, B, AND C CORES

In order to separate the two, equation (7) is divided through by the frequency, giving

$$\frac{R_t}{L f} = 8\pi\,\eta\,\mu\,B^{x-2} + 8\pi\,\gamma\,\mu\,f \qquad (8)$$

This equation represents a straight line when plotted with $\frac{R_t}{L f}$ as one of the coordinates and the frequency

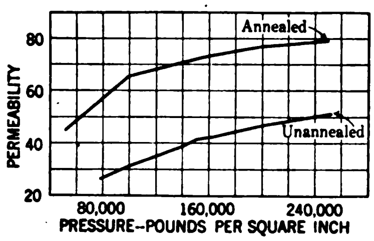

Fig. 13—Permeability at Low Magnetizing Forces for Uninsulated Iron Powder Cores Compressed With Different Pressures

as the other. The intercept of this line with the axis of $\frac{R_t}{L f}$ gives the effective resistance for a given flux density per henry per cycle, caused by the hysteresis loss. The slope of the line multiplied by the frequency gives the effective resistance, per henry per cycle, caused by the eddy current loss at that frequency.

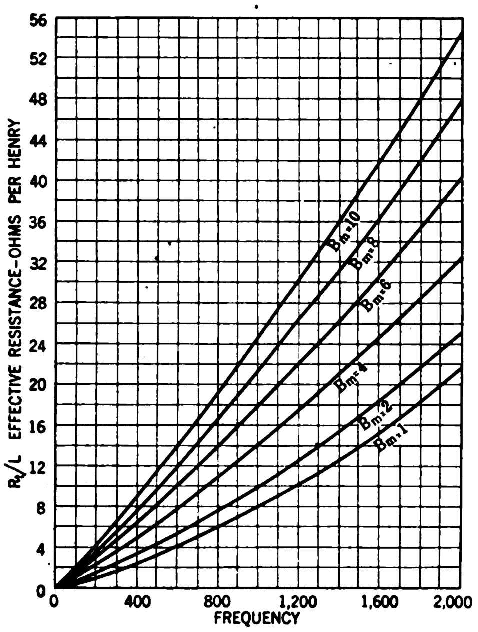

Fig. 14—Increase With Frequency in Effective Resistance Caused by the Core Losses, for Grade B Cores

The permeabilities and the magnetizing forces in the alternating-current measurements were computed by means of equations (3) and (4).

In Fig. 13 are plotted the permeabilities of the uninsulated iron-powder at low magnetizing forces and for different pressures.

In Fig. 14 $\frac{R_t}{L}$ is plotted against frequency for several densities for grade A material, and in Fig. 15 $\frac{R_t}{L f}$ is plotted against the frequency for the same flux densities.

Fig. 16 shows the variation of $\frac{R_t}{L}$ with frequency. The plot is for $B_m = 2$ gauss and permits a comparison of the three grades of material.

Fig. 17 shows, in per cent of the initial "a-c. permeability," the variation in a-c. permeability, which is

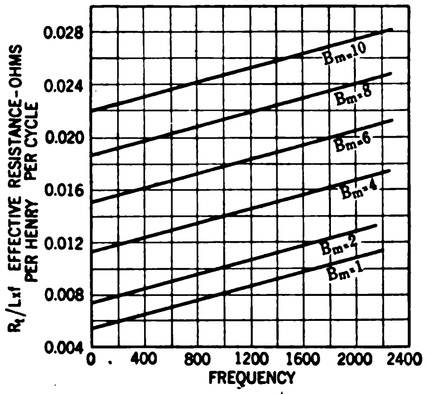

Fig. 15—Separation into its Components of Effective Resistance Caused by the Core Losses for Grade B Cores

produced by the superposition of various values of steady magnetizing force. In determining the relations of Fig. 17 the inductance bridge was used, and the a-c. permeability was calculated from the measured inductance of the test coil by the application of equation (3). In addition to the alternating current which was used for the bridge measurements there was superposed upon the windings of the test coil a direct current. The magnetizing forces corresponding to various values of the superposed d-c. are shown by the abscissas of Fig. 17. The figure illustrates the magnetic stability of the core material—a characteristic which will be discussed more fully later. It may be noted, however, that stability to superposed d-c. magnetizing forces is important in coils designed for telephonic purposes, for example, in loading coils which are to be used on composited circuits, where the inductance to the voice frequencies must not be greatly altered by the superposed telegraph currents.

Tables IV, V and VI, to which reference has already been made, give the results of computation based upon bridge measurements in addition to those derived from the ballistic measurements. Bridge measurements permit accurate determinations of the magnetic constants for low values of H. The higher values

were computed from ballistic measurements as mentioned above. The tables give hysteresis coefficients and hysteresis exponents and also energy losses per cm.[3] per cycle. The energy loss has been expressed per cm.[3] per cycle in the case of the bridge measurements to facilitate comparison with the corresponding values derived from ballistic measurements.

Discussion of Magnetic and Electrical Properties of Powdered Iron Cores

The data collected in the tables and curves give a fairly good idea of what can be done with compressed iron-powder for magnetic purposes.

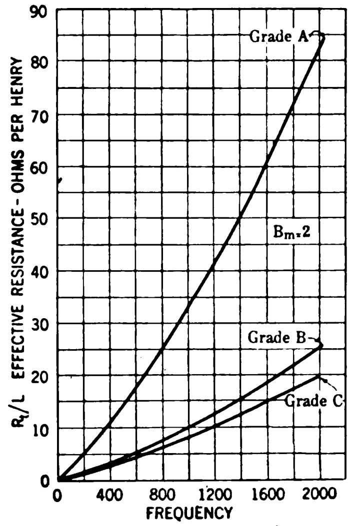

Fig. 16—Increase With Frequency in Effective Resistance Caused by Core Losses for Grades A, B, and C, With Constant B_m

When annealed, uninsulated, powder is compressed to 254,000 pounds per square inch, the specific gravity of the mass is 7.4 as compared to 7.6 for solid cast iron and 7.85 for solid wrought iron. The specific gravity of the unannealed powder at the same pressure is 6.7.

The greatest change in specific gravity occurs below 100,000 pounds pressure per square inch. (*cf.* Fig. 4). With this pressure the annealed uninsulated iron has a specific gravity of 7. For a pressure two and one-half times as large it is increased only to 7.4. Although the additional pressure increases the specific gravity very little, the maximum permeability for the same difference in pressures is more than doubled as is shown by Fig. 8. The additional pressure is, therefore, very effective in closing up the air gaps in the magnetic circuit. It appears also from Table I that high pressure is effective in producing an intermeshing of distorted iron grains which holds the compressed mass together and results in a mechanically strong structure. The microphotograph of Fig. 1 illustrates this intermeshing, as well as the thinness of the gaps between adjacent grains.

The measurements of specific resistance for cores pressed from uninsulated powder show the same characteristic variations as the specific gravity (Fig. 4). The specific resistance (Fig. 5) changes very rapidly with the pressure, for pressures below 100,000 pounds per square inch, but for higher pressures the change is more gradual. It is interesting to note that even when the specific gravity is 7. 4 the specific resistance of the compressed, uninsulated, powder is 50 to 60 times that of the solid iron.

The magnetic properties of compressed iron-powder are in general similar to those of solid iron rings. in which air gaps have been cut. The magnetization curves of Figs. 6 and 7 are sheared to the right as the value of the air gap is increased. This is due to the increase in the reluctance of the magnetic path. The magnetization curve for the highest pressure (Fig. 6) is very similar to one given by Ewing [16] for a wrought-iron bar cut into eight pieces.

There is quite marked difference between the permeabilities of the insulated and uninsulated powder. If we compare the uninsulated powder at a pressure of 150,000 pounds per square inch and a specific gravity of 7.1, with the grade A material, the specific gravity of which is the same, we find that the maximum permeability, and the retentivity of the former is more than double that of the latter. The permeability at low magnetizing forces shows a similar although

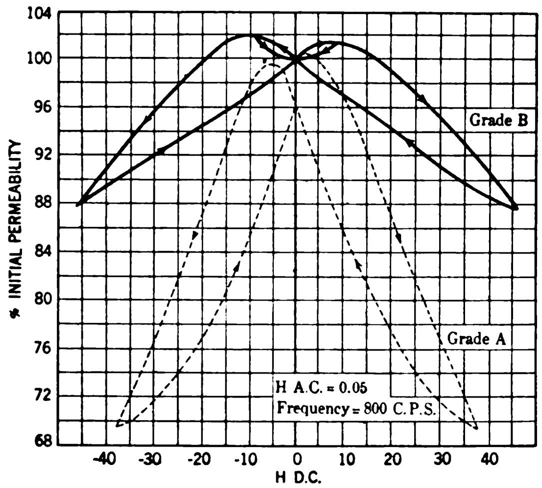

Fig. 17—The Effect of Superposed D-C. Fields on the A-C. Permeabilities of Grades A and B Cores

smaller difference. This difference is presumably caused by the way the air gaps are distributed in the two types of material. In the grade A cores each grain is insulated with a thin film which remains substantially intact while the grains are being distorted under the high pressure. In the uninsulated material it is probable that in certain parts of the mass the grains are pressed together until the air spaces between adjoining grains disappear but in other parts the air spaces are fairly large; hence the structure is that of a honeycombed mass.

16. J. A. Ewing. "Magnetic Induction in Iron and other Metals." 3rd Edition, 1900, page 292.

The maximum permeability recorded for compressed iron powder is 545. This is as high a permeability as can be obtained with many grades of solid iron as is evident from Table VII. In this table are given the maximum permeability, and the permeability for $H = 0$, for several kinds of iron and steel as tested by Gumlich and Rogowski[17], and also for several grades of compressed iron-powder as tested by the writers. For grades B and C the tabulated values of maximum permeability are those obtained with the highest magnetizing forces at which the coils were tested. At the magnetizing force of $H = 60$ the permeabilities were still slowly increasing.

TABLE VII.

Kind of Material	Permeability Maximum	$H = 0$
Electrolytic iron, wrought bar	7,800	250
Poor grade of cast steel, annealed	710	131.5
Poor grade of cast steel, hardened	170	58
Cast iron, annealed	620	175
Cast iron, unannealed	240	69.4
Iron powder, annealed, uninsulated, compressed with 254,000 pounds pressure	540	80
Iron powder, unannealed, uninsulated, compressed with 254,000 pounds pressure	156	52
Grade A iron-powder cores	156.5	54.8
" B " " "	57.2	30.2
" C " " "	48	26.3

The permeabilities of grades B and C are practically constant for flux densities below $B = 100$. For grade A this is true below $B = 50$. For flux densities below $B = 10$ there is no change in permeability that can be detected by accurate bridge measurements. This constancy is one of the important properties which makes our core-material useful for magnetic purposes.

The change in a-c. permeability when the cores are subjected to high d-c. magnetizing forces (*cf.* Fig. 17) is less for grade B than for grade A material. With a d-c. force of $H = 45$ the a-c. permeability of grade B is 85 per cent of the initial. When the force is removed the permeability returns to its original value. For grade A cores, with a d-c force of $H = 35$, the a-c. permeability is decreased to 70 per cent of its initial value and returns to 96 per cent when the d-c. force is removed.

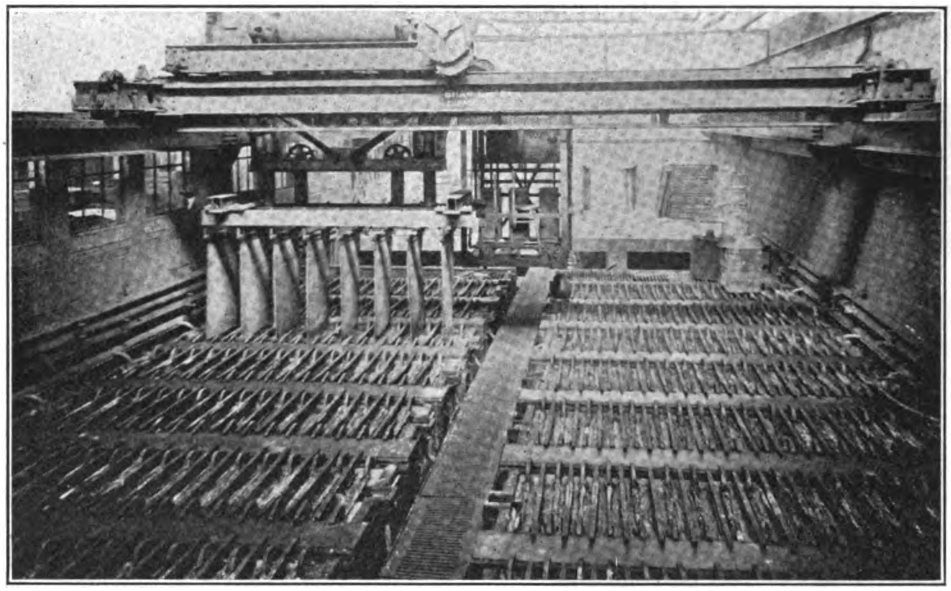

Fig. 18

For purposes of comparison it may be noted that in the case of 65-permeability iron-wire cores, which were mentioned above as standard prior to the development of the powdered iron, the stability is less than that of both grade A and grade B material. In the case of 65-permeability iron-wire cores the a-c. permeability may decrease to as little as 35 per cent of its initial value when a d-c. magnetizing force of $H = 45$ is superposed. When this superposed force is removed the permeability returns to only 62 per cent of its initial value.

From Tables IV, V and VI a comparison may be obtained of the present standardized grades of powdered iron as to the energy losses due to hysteresis. It will be noted that for flux densities below $B = 10$ the energy loss in grade A is approximately double that of grade B or grade C.

For the purpose of the design and operation of telephone equipment it is convenient to express energy losses implicitly in terms of an increase in effective resistance rather than explicitly, since the effective

17. E. T. Z. February 23, 1911.

resistance is a determing factor in the calculation of attenuations. Table VIII is added to permit a comparison of grades A, B and C in terms of increments in effective resistance. The values, there tabulated, represent differences between the resistance of test coils to currents of 800 cycles, and to direct currents, that is represent differences between effective and ohmic resistance at 800 cycles. In this table are indicated the components of the total increment in effective resistance due to hysteresis and eddy currents. The separation into components was effected by means of equations (7) and (8). The methods is illustrated by Figs. 14 and 15, but the actual values used in de-

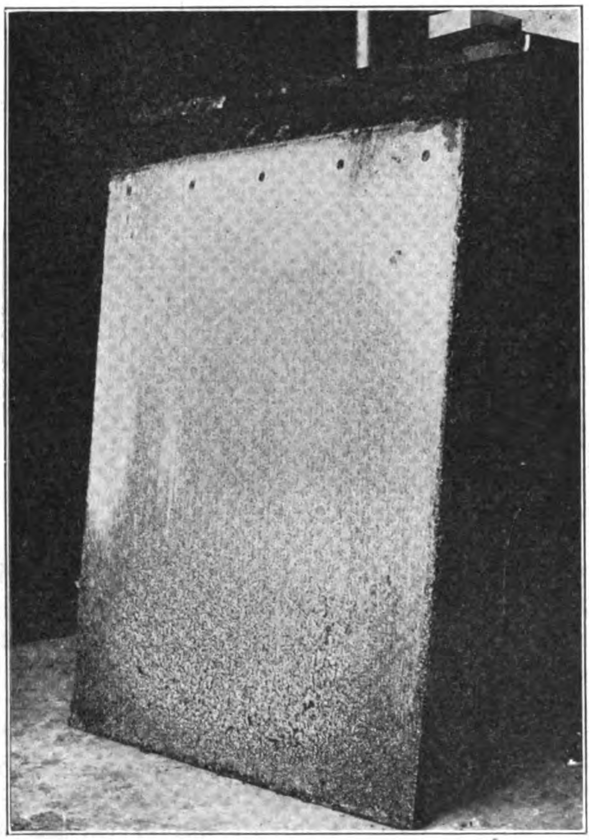

FIG. 19

termining the tabulated values were obtained from the data of Fig. 16, and correspond to the flux density of $B = 2$.

TABLE VIII.

	R_h per henry	R_e per henry	R_t per henry
Grade A cores.......	19.7	5.4	25.1
" B "	5.9	1.7	7.6
" C "	5.1	1.2	6.1

It will be noted that the effective resistance due to eddy currents is approximately 20 per cent of the total increment in effective resistance. The percentage would be less at higher flux densities as is evident from the relations of equation (7).

COMMERCIAL PRODUCTION OF POWDERED-IRON CORES

Powdered iron cores are today manufactured in large quantities by the Western Electric Company at Hawthorne, Illinois. The present equipment has a capacity of 25,000 pounds of iron powder per week.

In Fig. 18 is shown some of the equipment used in producing electrolytic iron.

It shows the electric crane lifting eight cathodes

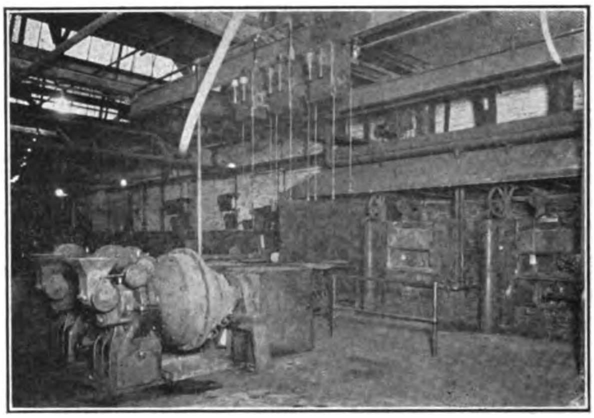

FIG. 20

with their electrolytically-deposited iron. In each tank there are sixteen cathodes and a corresponding number of anodes. In removing the cathodes only alternate ones are withdrawn at a time, partly for convenience in washing and handling, and partly so that the operating conditions in the tank will be less violently altered than if all the electrodes must be started fresh at once. The background of the figures

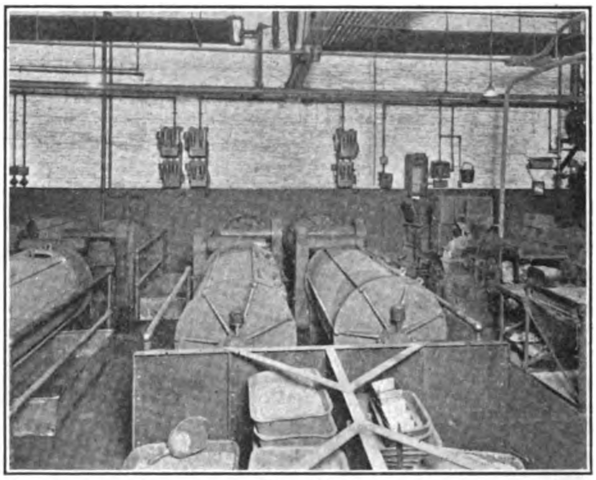

FIG. 21

shows the back of the switchboard and controllers, and also the stripping floor where the deposited iron is removed from the cathode plates.

A cathode with a full weight of electrolytic iron, ready for stripping is shown in Fig. 19.

After being stripped from the cathode the electrolytic iron is ground in a Hardinge conical-ball mill. Two of these mills are shown in Fig. 20. These mills

operate with automatic feeders and deliver their output to rotating brass sieves (80 meshes to the linear inch). In the illustration the sieves are not seen because of their rectangularly shaped iron covers. To the right of this illustration may be seen the annealing ovens.

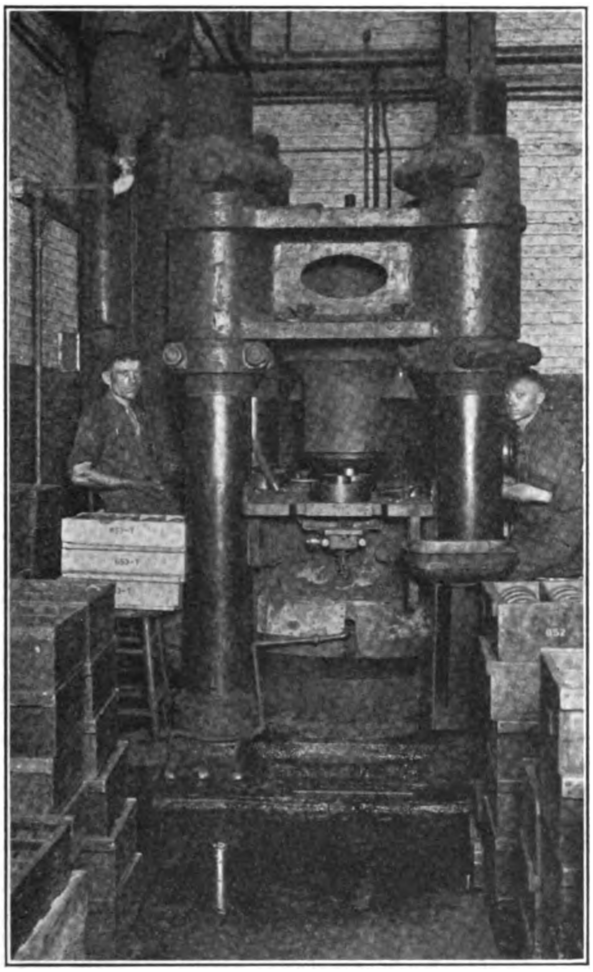

FIG. 22

The portion of the iron which is to be annealed is treated in cast-iron pots which hold about one hundred pounds each. Fig. 21 shows, at the extreme right, how the annealed iron appears as it is just being taken from the annealing pot. During the process of annealing the powdered iron is sintered to a fairly coherent mass. In order to reduce the iron to its original mesh the annealed product is passed through a rotary rock-crusher and a disk grinder. It is then sifted again by means of the jigger tables which may be seen at the right of the illustration.

The sifted powder is then rolled with flaked zinc in drums. The latter are worm-driven and four of them may be seen in the center of Fig. 21. At the extreme left of this figure may be seen four somewhat similar drums in which the powder is shellacked and dried. These are provided with steam ejectors for drawing a current of air through the shellacked mass as it dries and is slowly tumbled in the drum. For compressing the finished powder into cores there is used a short-stroke quick-acting hydraulic press which is shown in Fig. 22. This press is operated to produce a pressure of about 200,000 pounds per square inch of surface area of the finished ring. At times this press has been operated to give as high as 300,000 pounds per square inch. Severe requirements have, therefore, been imposed upon the design and construction of the steel die in which the material is compressed. The dies at present in use have been especially designed and treated and their perfection is such that several thousand rings may be pressed from a single die before it must be discarded because of wear, cracks or distortion.

The plant which has just been described has been in operation for about five years and has produced an enormous number of cores which are today widely distributed over the United States in the telephone plant of the Bell System.

A combination radio and wireless telephone station will shortly be in operation in the City of Chihuahua, Mexico, according to Consul J. B. Stewart. The station will have a range of 6000 miles, thus putting Chihuahua in direct communication with all parts of the United States, Europe and other countries. Stations will probably be installed at Ojinaga and Ciudad Juarez and, later on, at Madera, Chihuahua.—*Commerce Reports*.

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

THE SALT LAKE CITY CONVENTION

This issue of the JOURNAL goes to press just at the time the Annual and Pacific Coast Convention is about to convene at Salt Lake City. The Convention Committee, with its numerous sub-committees, has made elaborate preparations for the entertainment of members and guests in attendance, and the excellent technical program which has been provided, combined with the natural scenic attractions of the Convention city and its environs, will afford an instructive and enjoyable occasion for all present. A full account of the meeting will appear in the August JOURNAL.

ANNUAL REPORT OF THE BOARD OF DIRECTORS

FOR THE YEAR ENDING APRIL 30, 1921

The annual report of the Board of Directors of the A. I. E. E. was presented at the annual business meeting of the Institute held in New York on Friday evening, May 20, 1921.

This report consists of a brief summary of the principal activities of the Institute during the year, including abstracts of various reports submitted by officers and committees, covering their respective branches of work. Inasmuch as most of the matters of importance referred to in the report have been, or will be, covered in much more detailed form in the JOURNAL the report will not be published in full herein, but any member of the Institute may obtain a pamphlet copy upon application to the Secretary of the Institute.

The Board of Directors held nine regular meetings during the year; four of these were held in New York, one at White Sulphur Springs, W. Va., one at Philadelphia, one at Chicago, one at Akron and one at Pittsburgh.

During the year President Berresford attended many Institute and Section meetings including the Annual and Midwinter Conventions and meetings in New York, Philadelphia, Chicago, Akron, Pittsburgh, Cleveland, Detroit-Ann Arbor, Indianapolis-Lafayette, Milwaukee, St. Louis and Schenectady

The Institute year just ended has more than fulfilled all predictions of continued growth, exceeding all previous years in committee activities, meeting attendance, and membership increase. The widespread desire to participate more actively in A. I. E. E. affairs is evidenced in the addition of six new Sections. The Branches have likewise shown a similar growth. The applications for membership received during the year were 2442; the net increase in membership amounting to 1870 or 71% over the preceding banner year. The following tabulation indicates the present membership, and the additions and deductions during the year:

	Honorary Member	Fellow	Member	Associate	Total
Membership, April 30,1920.	6	498	1615	9226	11345
Additions:					
Transferred.....	....	45	225	....	....

Reinstated......	....	3	6	78	....
Deductions:					
Died..........	....	3	6	46	....
Resigned........	....	4	12	138	....
Transferred.....	....	....	35	235	....
Dropped........	....	3	14	338	....
Membership, April 30,1920.........	6	541	1903	10765	13215

Net increase in membership during the year.......................1870.

The six Sections organized were at Akron, Ohio; Cincinnati, Ohio; Syracuse, N. Y.; Omaha, Neb.; Lehigh Valley with headquarters at Bethlehem, Pa.; and Connecticut with headquarters at New Haven. The following figures indicate the activities of the local organizations:

	For Fiscal Year Ending						
	May 1 1915	May 1 1916	May 1 1917	May 1 1918	May 1 1919	May 1 1920	May 1 1921
SECTIONS							
Number of Sections..	31	32	32	34	34	36	42
Number of Section meetings held......	246	251	265	245	217	262	303
Total Attendance....	23,507	28,553	31,299	34,614	25,837	30,741	37,823
BRANCHES							
Number of Branches.	52	54	59	59	61	62	65
Number of Branch meetings held......	328	360	368	268	156	360	443
Attendance..........	12,712	15,166	16,107	10,683	6,441	16,827	21,629

The Finance Committee's report together with the General Balance Sheet and detailed financial statements of the certified public accountants who audited the Institute books are included in the report and show that there has been a deficit of $13,892.12, which is accounted for largely by the large increase in cost of publication, one of the chief items of expense in Institute work. All activities have been carried on without curtailment and without increase of dues. In view of proposals now being considered by the Board of Directors and from reductions already evident, it is expected that the expenses for the coming year will be within the income of the Institute.

AMERICAN ENGINEERING COUNCIL

MEETING OF THE EXECUTIVE BOARD

The fourth meeting of the Executive Board of American Engineering Council was held in St. Louis on June 3, 1921. This was the first anniversary of the Organizing Conference which met in Washington last year. The meeting was well attended and full of interest, many matters of importance being discussed. One of the pleasant features was the cordial hospitality extended by the engineers of St. Louis, who entertained with an automobile drive and dinner. As a result of invitations to the leading engineering organizations in the vicinity of St. Louis a number of their representatives attended the meeting.

New Member Societies

Upon recommendation of the Committee on Membership and Representation the following organizations were admitted to charter membership in the Federated American Engineering Societies:

Iowa Engineering Society
Jamestown Engineering Society
American Society of Safety Engineers.

Considerable sentiment has developed in favor of extending the time for charter membership and as a result the Board decided to bring this matter before the next American Engineering Council meeting in January. However, all Societies which make application on or before July 1, 1921 may become charter members.

Activities of the Federation throughout the country were reported upon by the Committee on Regional Activities, showing the progress that was being made towards securing additional member organizations.

Status of F. A. E. S. and A. A. E.

During the course of the meeting some discussion took place as to the status of the Federated American Engineering Societies and the American Association of Engineers. Mr. H. O. Garman, President of the A. A. E., on being introduced announced that he had been elected President of the A. A. E. on a platform of harmony and cooperation with the F. A. E. S. It was decided that a committee of three should be appointed from each organization to determine upon the status of the two. The committee from the F. A. E. S. is composed of Messrs. Calvert Townley, Dexter S. Kimball and L. W. Wallace.

Elimination of Waste in Industry

A feature of the meeting was the presentation and consideration of the preliminary summary of the report of the Committee on Elimination of Waste in Industry. This was discussed at length. It was decided that the summary and the full report should be carefully edited in keeping with suggestions made by members of the Executive Board and that the Committee on Procedure be authorized to accept the offer of the American Society of Mechanical Engineers to arrange for the publication of the complete report in book form.

The report covered thorough investigations made by the committee since its appointment last January and disclosed vital causes of waste in industry, with suggestions for elimination. "Over 50 per cent of the responsibility for these wastes can be placed at the door of management and less than 25 per cent at the door of labor," it was stated. The investigators found that the margin of unemployment amounts to more than a million men, and that billions of dollars are tied up in idle equipment. High labor turnover was named as an index of one of the commonest wastes. A waste that runs into millions annually was reported as the loss of time and energy and money through duplication of estimates and bids in the building trade.

To aid in wiping out such wastes the report outlined a plan of nationwide cooperation between the government, the public, trade associations, the industries, labor, bankers, and engineers, indicating in what way each of these could help to solve the problem.

Announcements as to when and where copies of this report may be obtained will be made later.

A unanimous vote of thanks was tendered to the committee in appreciation of the amount of work done on the report.

Licensing of Engineers

The Committee on Licensing submitted a report containing its new recommendations on the uniform law. The committee was authorized to hold a hearing in the near future for the purpose of obtaining suggestions as to the form licensing of engineers should take.

Employment Service

A progress report of the Special Committee on the Employment Service was received. A further report from this committee will be given at the next meeting of the Executive Board.

Public Affairs Committee

The following recommendations of the Public Affairs Committee were given the approval of the Executive Board:

That no action be taken in legislation pertaining to the Federal Power Commission.

That engineering research among the colleges be fostered by Government support regardless of whether the institutions were land grant colleges or not.

That the question of legislation covering the Federal road building program be referred to the division of the National Research Council that is investigating this subject.

That if the Government wished to make an investigation of Muscle Shoals on its account by a competent engineer, Council would suggest the names of engineers to assist in making the investigation, should it be asked to do so.

That American Engineering Standards Committee plan for obtaining cooperation with the Government department be sanctioned.

Topographic Mapping Program

The Board approved support for the present bill in Congress to give increased assistance to the topographic mapping program recommended by the Board of Surveys and Maps.

Payment for Estimating

The Committee on Payment for Estimating reported that the Associated General Contractors of America and the American Institute of Architects had approved its report. The Board added its approval, and the report is to be printed in pamphlet form and given wide distribution.

Personnel Research Federation

The recommendations concerning cooperation of the Personnel Research Federation were carried over for further consideration. This federation was organized on March 15 last, to bring about interchange of research information among the numerous organizations which are engaged in personnel research. (See April, 1921, JOURNAL, p. 347.)

Representation in Building Industry

The question of representation on the National Conference Board of the Building Industry was referred to the Committee on Procedure with power in event this matter should again be brought up by the Department of Labor or the Department of Commerce.

Upon recommendation of the Committee on Procedure, Mr. J. P. Healey of Washington, D. C., was appointed alter-

nate to Rudolph P. Miller on the National Board of Jurisdictional Awards in the Building Industry.

Activities of Foreign Relations Committee

The Committee on Foreign Relations reported that it had participated in the reception and entertainment of a delegation of Italian engineers and that similar participation would be had in the entertainment of a small delegation of French engineers now visiting in this country.

A resolution to the professional engineers of Great Britain was approved by the Board expressing the admiration of the Federated American Engineering Societies for the effective work of British engineers during the war, and sympathy for the sacrifice of life, health and property. A special committee was appointed to draft a suitable resolution to the French engineers.

Resolutions to Herbert Hoover

Resolutions to Mr. Herbert Hoover which had been drafted by a special committee were approved, and it was ordered that they be engraved and forwarded to Mr. Hoover. The resolutions put on record the appreciation of the Executive Board of American Engineering Council for Mr. Hoover's judgment and vision in directing the initial policies of The Federated American Engineering Societies, and expressed the regret with which his resignation from the presidency had been accepted, with good wishes for a continuation of the distinguished success which has followed him in his past services to his profession, his country and mankind.

Next Meeting in September

The next meeting of the Executive Board will be held in September, the time and place to be announced later.

AMERICAN ENGINEERING STANDARDS COMMITTEE

A. I. E. E. STANDARDS SUBMITTED FOR APPROVAL

The American Institute of Electrical Engineers has submitted its Standards (1921 edition) to the American Engineering Standards Committee for approval as an American Standard. The Standards are submitted in accordance with the special provision in the procedure of the committee under which important standards adopted or in process prior to 1920 may be approved without going through the regular process followed in new work. The standards submitted represent the latest revision of the A. I. E. E. standardization rules, revised during 1919 and 1920. The first edition of the rules was issued in 1899.

The American Engineering Standards Committee would be very glad to learn from those interested of the extent to which they make use of these specifications and to receive any other information regarding the specifications in meeting the needs of the industry.

The Standards of the A. I. E. E. are issued in a 172-page book in flexible cloth binding. Copies may be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York, price $2.00; or from the A. I. E. E., with a discount of 25 per cent to Institute members.

COPPER SPECIFICATIONS APPROVED

Standards recently approved by the American Engineering Standards Committee include four Copper Specifications submitted by the American Society for Testing Materials as "Tentative American Standard," as follows:

9-1921 Soft or Annealed Copper Wire.
10-1921 Lake Copper Wire, Bars, Cakes, Slabs, Billets, Ingots, and Ingot Bars.
11-1921 Electrolytic Copper Wire Bars, Cakes, Slabs, Billets, Ingots, and Ingot Bars.
12-1921 Battery Assay of Copper.

SECTIONAL COMMITTEES RECENTLY DESIGNATED

Standard of Aluminum for Conducting Purposes

In compliance with the request of the American Institute of Electrical Engineers, the American Engineering Standards Committee has designated the A. I. E. E. sponsor for the formation of a sectional committee on "Standard of Aluminum for Conducting Purposes."

Symbols for Electrical Equipment of Buildings and Ships

n conformity with the request of a conference of interested national organizations, the A. E. S. C. has designated the American Institute of Architects, the American Institute of Electrical Engineers, and the National Association of Electrical Contractors and Dealers, joint sponsors for a sectional committee on Symbols for Electrical Equipment of Buildings and Ships.

Mining Standardization

Upon recommendation of its General Correlating Committee for Mining Standardization, the A. E. S. C. has authorized the organization of sectional committees on "Safety Rules for Installing and Using Electric Equipment in Bituminous Coal Mines," "Portable Electric Mine Lamps," and "Storage Battery Locomotives for use in Gaseous Mines." The U. S. Bureau of Mines has been designated as sponsor for each of these sectional committees.

1920 ENGINEERING INDEX ISSUED

The American Society of Mechanical Engineers has just issued the 1920 volume of The Engineering Index, which has been delayed because of the printing situation. The volume retains the alphabetical index found satisfactory in the 1919 volume. It contains nearly 14,000 items referring to articles in some 700 engineering and technical publications, and is a comprehensive guide to the engineering literature of 1920.

Copies of the 1920 volume may be obtained from the American Society of Mechanical Engineers, 29 West 39th Street, New York City. The price is $6.00.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Wm. J. Cochran, 248 Wellesly St., Toronto, Ont., Can.
2.—R. Coelho, 210 West 95th St., New York, N. Y.
3.—L. de La Pena, 13 Olozaga, Madrid, Spain.
4.—Frederick G. Doane, Box 168, Groton, Conn.
5.—W. F. Gantvoort, Kedongsarie 84, Soerabaia, Java, Dutch East Indies.
6.—Louis E. Given, 72 West Adams St., Room 634, Chicago, Ill.
7.—I. Goldberg, 35 Euclid Ave., Toronto, Ont., Can.
8.—Jonathan M. Keller, Box 121, Sparrows Point, Md.
9.—John Neilson, 344 West 72nd St., New York, N. Y.
10.—Basil B. Pilcher, 691 East 230th St., New York, N. Y.
11.—M. J. Pouillon, 95 Straps St., Gent, Belgium.
12.—Albert G. Scholer, Dundee Lake, N. J.
13.—Martin Tracy, Tunnel Camp, Brittiania Mines, Howe Sound, B. C., Can.
14.—Harry Wilson, J. G. White Engg. Corp., Marcus Hook, Pa.

JOHN FRITZ MEDAL AWARDED TO EUGENE SCHNEIDER

The John Fritz Medal Board of Award has awarded its gold medal and diploma to Charles Prosper Eugene Schneider, the distinguished French engineer, scientist, and man of affairs. This high honor bestowed by American engineers was awarded to Mr. Schneider, "for achievement in metallurgy of iron and steel; for development of ordnance, especially the 75 mm. gun, and for notable patriotic contribution to the winning of the war."

Mr. Schneider heads the great Creusot engineering and steel works and shipbuilding plants of France, which with their subsidiaries have 100,000 employees. No industrial establishment in the whole world made a greater contribution to the defense of liberty or showed more wonderful resourcefulness under the stress of war from 1914 to 1918.

Mr. Schneider has led not only in the technical and commercial development of the great and varied steel and other engineering industries of France, but he has also given effective attention to the well-being of his men and their families. His schools for workmen, foremen and engineers are among the best in the world. As early as 1877 his company introduced a pension system, antedating similar action by the French Government. A very large proportion of his men own their own houses and gardens. He has successfully done much to raise the standards, broaden the outlook and bind the loyalty of his men.

Born October 29, 1868, at Le Creusot, he has devoted his life to the development of the great industries which his forefathers founded. Upon the death of his father in 1898, he became the head of the company, when only thirty years of age. He was a member of the Chamber of Deputies, of the French Parliament from 1898 to 1910. He has received many honors in his own and other countries for his noteworthy achievements. While in the United States in November 1919, he was presented with the gold medal of the Mining and Metallurgical Society of America. His noble and lovable personality has won many friends.

The medal and diploma will be presented to Mr. Schneider in France by a party of distinguished American engineers which sailed for Europe in June. This party is led by Mr. Ambrose Swasey, Chairman of the Board of Award, and includes several other officers and past officers of the national societies of Civil, Mining and Metallurgical, Mechanical, and Electrical Engineers of the United States. It was scheduled to present the 1921 award to Sir Robert A. Hadfield in England on June 29th, as announced in a previous issue of the JOURNAL. The award to Mr. Schneider is for 1922, anticipated so that the same deputation might continue to France to make the presentation, which will take place early in July.

PERSONAL MENTION

G. M. EVANS, consulting engineer of New York City, is at present with Easton & Evans, Keeseville, N. Y.

FORREST E. BROOKS has left the New York Telephone Company to become chief engineer for the Cole Process Company of America, Inc., New York City.

THEOPHILUS JOHNSON, JR., has become general manager of the Wireless Specialty Apparatus Company, Boston. He was formerly with the General Electric Company.

ALEX DOW, president and general manager of the Detroit Edison Company, has been appointed a member of the board of directors of the Detroit United Railway.

W. J. CRAWFORD is now with the Electric Storage Battery Company, New York City. Until recently he was sales engineer for the Cutler-Hammer Mfg. Company, New York.

WM. S. GOULD, who was with John A. Stevens, at Lowell, Mass. and Cleveland, Ohio, is now in the Engineering Department of The Cleveland Discount Company, Cleveland.

J. B. ADAMS has become sales manager for Schweitzer & Conrad, Inc., Chicago. Mr. Adams left the Standard Insulation Company, Rutherford, N. J., to take up his new work.

C. A. MALINOWSKI has left his position as electrical foreman of the Magna Plant of the Utah Copper Company, and is now with the Westinghouse Electric Company, Salt Lake City, Utah.

COLIN K. CARR, formerly with the Firestone Tire & Rubber Company, Akron, Ohio, has entered the employ of the Commonwealth Edison Company, Chicago. He will be in the Operating Department.

FRANK M. KNIGHT, formerly electrical draftsman with ALBERT C. WOOD, consulting engineer of Philadelphia, is now in the Shop Engineers Office of the Lima Locomotive Works, Inc., Lima, Ohio.

CHARLES S. HAMNER, of the firm of Hamner & Quick, general engineers and inspectors, announces that the group of engineers of which his firm is a part has greatly enlarged its quarters at 35 Nassau Street, New York City.

JOHN W. BOWDLE, of the Pacific Telephone & Telegraph Company, has been transferred from San Diego, Cal., to Los Angeles, as switchboard engineer. His work in San Diego was that of wire chief.

H. H. HORNING has left the Cutler-Hammer Mfg. Company of Milwaukee, and is now located with the Power Engineering Department of The Philadelphia and Reading Coal and Iron Company, Pottsville, Pa.

P. D. WAGONER has located with the Elliot-Fisher Company, in the Canadian Pacific Building, New York City. Mr. Wagoner was until recently an executive with the General Motors Corporation, New York.

VINCENT J. WOODCOCK is now connected with the Crowe-Woodcock Company, Worcester, Mass. He was formerly manager of the Electric Fixture & Appliance Departments of the Economy Electric Company, Worcester.

M. A. MAXWELL has recently become vice-president and general manager of the Beckley Pocahontas Coal Company, Huntington, W. Va. His former position was general manager of the Logan County Light & Power Company, Logan, W. Va.

CHARLES G. DU BOIS, president of the Western Electric Company, has lately returned from a six weeks' visit to Europe, where he made a study of European economic conditions. He traveled in France, Switzerland, Austria, Hungary, Germany, Belgium, and England.

H. E. KAIGHN, consulting engineer, has severed his active connection with the Wilmington Sugar Refining Company, and has resumed his general practise with offices at 3143-45 Du Pont Building, Wilmington, Del. He is still retained by the company as a consulting engineer.

W. W. HEADINGS, who has been with the Carballoy Products Company, Bellevue, Ohio, as chief engineer, has secured a fellowship at the Carnegie Institute of Technology, where he is an instructor in the Physics Department, and is also doing research work on developing carbons for electrical purposes.

ALLAN V. GARRATT has opened an office in Boston, at 176 Federal Street, for consultation and advisory work in hydraulic engineering. Mr. Garratt was formerly chief engineer of the Lombard Governor Company, and more recently consulting hydraulic engineer to Lockwood, Greene & Company, Engineers.

AARON L. NELSON, of Deer Lodge, Montana, has sailed for South America. His address will be: General Electric Company, Caixa Postal 547, Sao Paulo, Brazil, S. A. Mr. Nelson has been with the General Electric Company since 1909, and represented it in the electrification of the Chicago, Milwaukee and St. Paul Railway.

A. E. KENNELLY, professor of electrical engineering at Harvard University and the Massachusetts Institute of Technology, sailed in June to take up his work as exchange professor in French Universities. (See June JOURNAL, page 506.) Dr. Kennelly will spend a year in France, on leave of absence from his positions here.

LOUIS COHEN, consulting engineer, Signal Corps, sailed for France on June 7th to attend the meetings of the Provisional Technical Committee of the International Conference on Electrical Communication. Dr. Cohen, Major General George O. Squier, and Major Joseph O. Mauborgne will represent the War Department at this conference.

CHARLES H. DRAKE, formerly assistant division traffic engineer with the Western Union Telegraph Company, Lake Division, Chicago, has been appointed supervisor of automatics for the Canadian National Telegraphs, with headquarters at Toronto, Ontario. Mr. Drake has been identified with the development and operation of automatic printing telegraphs since 1913.

E. J. CONDON, JR., has become assistant general manager of the Intermountain Railway, Light & Power Company, with headquarters in Colorado Springs, Colo. Mr. Condon is also vice-president of the Condon Engineering Company of Chicago, and has held executive positions with the Indiana Utilities and other companies, his work bearing especially on central-station operation.

C. W. KOINER has been appointed city manager for Pasadena, Cal., with power of administration in all departments of the city except the library and legal. Mr. Koiner has been general manager and mechanical-electrical engineer of the city's Electric Utility for thirteen years, having had previous to that time a wide experience in the construction and management of electrical plants.

JAMES DIXON, who for the past year has been production manager of the Reliance Electric and Engineering Company of Cleveland, Ohio, has been made works manager of that company. Prior to joining the Reliance staff Mr. Dixon was employed by the Crocker Wheeler Company at Ampere, N. J., for ten years in various capacities. During the war he was enrolled as junior lieutenant in the Naval Reserve, but was not called to active service.

G. C. THORNTON has opened an office at 308 First National Bank Bldg., Huntington, W. Va., for the practise of Electrical Engineering, specializing in designing and supervising construction of steam and electric power plants for mines, and the mining and handling of coal by machinery. Mr. Thornton has had broad experience in this line of engineering, having installed some of the largest plants in the Alabama coal fields, prior to the war, during which he served as Major, Corps of Engineers.

P. G. AGNEW has returned from a short trip to Europe to attend a conference in London of the secretaries of the national standardizing bodies. (A brief account of this conference, as *The Engineer*, London, reviewed it, will be found on page 560 of this issue of the JOURNAL.) Dr. Agnew visited France, Switzerland, and Germany after the conference, to make a more detailed study of the standardization work in those countries.

PHILIP BELL WOODWORTH has been elected president of Rose Polytechnic Institute at Terre Haute, Ind. Dr. Woodworth is an engineer of wide practise as well as teaching experience, most of his engineering work being done under the firm name of Rummler, Rummler & Woodworth, attorneys and engineers. For a number of years before the war he was dean and professor of electrical engineering at Lewis Institute, Chicago. Since 1917 he has been in government service serving successively as executive secretary of the National Council of Defense, regional director for the North Central States, in charge of vocational training for enlisted men, and corps consultant of the War Plans Division of the U. S. Army, at Fort Sheridan, which position he is leaving to accept the one at Terre Haute. Rose Polytechnic Institute is an engineering college of the first rank. It was opened in 1883, and has graduated a long line of engineers, many of whom have become distinguished in their profession. Dr. Woodworth will enter upon his new duties at once.

OBITUARY

FRANK TAYLOR GASH, of the West Penn Power Company, Springdale, Pa., died on May 23, 1921 in his 34th year. Mr. Gash was born in California, and was graduated from the Polytechnic College of Engineering at Oakland, Cal. Most of his life was spent in California until he located in the east after the war, except for an interval of about two years during which he was with the Westinghouse Electric & Mfg. Company of E. Pittsburgh. He died suddenly in Tarentum, Pa., where he made his home. Mr. Gash had been an Associate of the INSTITUTE since 1912.

CHARLES NELSON VANDERHOOF of Newark, N. J., died in that city on April 19, 1921. Mr. Vanderhoof was born September 16, 1881, in Newark. He began his career at an early age on construction work with the Westinghouse Elec. & Mfg. Company. Leaving this position, he was employed for several years in the same line of work with the New York Edison Company. He entered the employ of the Public Service Electric Company of N. J. in July 1903. During eighteen years' service with this company, he held the following positions: Wireman, electrician, foreman, and division foreman in charge of electrical construction work. Mr. Vanderhoof's devotion to duty and untiring energy were exceptional. He had an excellent character and pleasing personality and consequently had a wide circle of friends. He joined the INSTITUTE in 1915. He was also a member of the National Electric Light Association, and of a number of fraternal orders.

CLARK WILSON FRANCY died on May 6, 1921, at a military hospital, Oteen, North Carolina. Lieutenant Francy's death followed an operation which it had been hoped would effect his recovery from illness contracted in the trenches during service overseas. He had been confined to military hospitals since his return to this country in April 1919. Lieutenant Francy was born in Toronto, Ohio, in 1886, and resided there

practically all of his life. He was graduated from the Case School of Applied Science in 1910 and started to work at once with railway and lighting companies in Ohio, becoming chief electrician for the Steubenville & E. Liverpool Ry. & Lt. Company. He was highly regarded by his associates as a man of sterling qualities. He had been a student member of the INSTITUTE in his college days, and became an Associate in 1916.

WILLIS H. TRENNER. Word has been received of the death of Willis H. Trenner on March 12, 1921. Mr. Trenner was chief engineer and superintendent of power of the Idaho Power Company, Boise, Idaho. His engineering career started upon his graduation from the Washington State College in 1903. He was employed in Tacoma, Wash., until 1905; next with the Portland Ry., Light & Power Company, in charge of electric design and construction of stations and substations, for two years; and from 1908 until his death he was in Idaho, first as superintendent of the Idaho-Oregon Light & Power Company, and then with the Idaho Power Company as above. Mr. Trenner was born at Goldendale, Wash., in 1879. He joined the INSTITUTE in 1911.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES MAY 1-31, 1921

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

APPLIED ELECTROCHEMISTRY AND METALLURGY.

By Charles F. Burgess, H. B. Pulsifer and B. B. Freud. Chicago, American Technical Society, 1920. 198 pp., illus., 8 x 6 in., cloth. $2.50.

A volume intended for the beginner or the reader desiring a concise summary of the most important commercial processes. The electrochemical section treats of such applications of electricity as electric furnaces, electroplating, the electrolytic refining of metals, and electrical discharges in gases. The metallurgical section reviews the customary practise in the metallurgy of iron, copper, lead, zinc and gold.

DIE BERECHNUNG ELEKTRISCHER LEITUNGSNETZE IN THEORIE UND PRAXIS.

By Josef Herzog and Clarence Feldman. Dritte auflage. Berlin, Julius Springer, 1921. 731 pp., diagrams 9 x 6 in.

The third edition of this thorough treatise on conducting networks has been thoroughly revised and enlarged, so that the treatment is both more extensive and more intensive than before. The book is a systematic theoretical and practical discussion of the subject, from the simplest conducting systems to the distribution of current and pressure in long conductors. Bibliographies are appended to the various chapters.

THE ELECTRODEPOSITION OF COPPER, AND ITS INDUSTRIAL APPLICATION.

By Claude W. Denny. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitman's technical primer series.) 108 pp., illus., 7 x 4 in., boards, $1.00.

The object of this small book is to touch on the principles of electrodeposition from a practical point of view, and to give special attention to the rapid strides made during the last five or six years, owing to the shortness of copper and as adjunct to existing methods of manufacture.

THE ENGINEER.

By John Hays Hammond. N. Y., Charles Scribner's Sons, 1921. (Vocational Series). 194 pp., 7 x 4 in., cloth. $1.25.

Mr. Hammond's book is intended as guide and counsellor for the youth attracted toward engineering as a profession. Its advantages and disadvantages, the qualities required for success, the best kind of education are clearly set forth, followed by chapters which explain the fields occupied by the major divisions of engineering—mechanical, civil, mining, chemical marine and military. The book is well fitted to assist in the selection of a career.

L'ETHER ET LA THEORIE DE RELATIVITE.

By Albert Einstein. Paris, Gauthier-Villars et Cie, 1921. 15 pp., 9 x 6 in., paper. 2.50 fr.

This short pamphlet is a translation of a lecture delivered at the University of Leyden on May fifth, 1920, in which the theory of action at a distance and the undulatory theory of light are discussed in relation to the existence of ether.

FUNFSTELLIGE TAFELN DER KREIS—UND HYPERBELFUNKTIONEN.

By Keiichi Hayashi. Berlin, Walter de Gruyter & Co., 1921. 182 pp., 9 x 6 in., paper. (Gift of the Author).

The values given in this table are in ten-thousandths from 0 to 0.1, in thousandths from 0.1 to 3, in hundredths from 3 to 6.3 and in tenths from 6.3 to 10. The circular and hyperbolic functions of any number are printed side by side, making it unnecessary to consult two places when using formulas containing both functions.

HILFSBUCH FUR DIE ELEKTROTECHNIK.

By Karl Strecker. Neunte auflage. Berlin, Julius Springer 1921. 662 pp., illus., 8 x 5 in., cloth. 70 M.

The ninth edition of this handbook, the first in eight years, follows the lines of the earlier editions, but has been thoroughly revised and largely rewritten. Considerations of cost have caused the omission of those sections devoted to weak-current engineering, primary cells, electric igniting and similar topics, so that the book is now concerned only with heavy-current work. Like earlier editions, this contains numerous useful references to important literature on various subjects.

AN INTRODUCTION TO TECHNICAL ELECTRICITY.

By S. G. Starling. Lond., Macmillan and Co., Ltd., 1921. (Macmillan's Life and Works Series). 181 pp., illus., 7 x 5 in., cloth. (Gift of The Macmillan Co., N. Y.) $2.00.

An elementary text-book addressed to students who require instruction in electricity of a practical kind, closely related to actual practise. Intended for use for vocational instruction in elementary and continuation schools.

Lehrgang der Schaltungsschemata Elektrischer Stark-strom-Anlagen.

By J. Teichmuller. 1. Band. Schaltungsschemata fur Gleichstromanlagen. 2. Auflage. Munchen und Berlin, R. Oldenbourg, 1921. 131 pp., diagrams, 12 x 9 in., boards. 60 M.

This work comprises diagrams of wiring and connection diagrams for direct-current generating stations of many kinds, accompanied by explanatory notes. The schemes shown include wiring for plants with and without storage batteries, voltage regulation, three-wire systems, stations for light and power, substations and measuring instruments. There are also given the wiring plans of a number of German central stations for general and special purposes.

The Microscope; Its Design, Construction and Application.

Edited by F. S. Spiers. Lond., Charles Griffin & Co., Ltd.; Phila., J. B. Lippincott Co., 1920. 260 pp., plates diagrams, 10 x 7 in., cloth. $5.00.

This volume contains the papers and addresses delivered at a meeting held in January, 1920, at the initiative of Sir Robert Hadfield, by the Faraday Society, the Royal Microscopical Society, the Optical Society and the Photomicrographic Society. One purpose of the symposium was to stimulate the study of and research in microscopical science by indicating lines of progress in the design of the instrument, showing recent improvements in the microscope and its technique, and its varied uses as an instrument of research.

The papers cover a wide field, including among other subjects the mechanical design, optics and manufacture of microscopes; their applications especially in metallography, metallurgy, engineering and metrology; their testing. An historical introduction is given and a bibliography of the chief literature.

Municipal Engineering.

By H. Percy Boulnois. Lond. and N. Y., Sir Isaac Pitman & Sons. Ltd., 1921. (Pitman's technical primer series.) 103 pp., 7 x 4 in., boards. $1.00.

This small volume is an introductory essay on the profession intended to draw attention to its present position and increasing importance, and to point out to those who think of embracing it as a vocation, the manner in which they should be equipped and the subjects they should study.

National Electrical Safety Code

Issued by the U. S. Bureau of Standards. Third edition. Wash., Govt. Printing Office, 1921. (Handbook series no. 3). 366 pp., 8 x 5 in., cloth. $.40.

About four years ago the Bureau of Standards published the completed text for this Code for examination and trial use, an early revision being contemplated. War conditions interfered with this trial, so that the publication of a new edition has been greatly delayed. The revision is now completed and the revised code is now published in this handbook for more convenient use. The discussion of the rules has been segregated under a separate cover so as to reduce the bulk of the main volume, and will appear as Bureau of Standards Handbook No. 4, now in press.

Oil Fuel.

By Edward Butler. Fourth edition. Lond., Charles Griffin & Co., Ltd., Phila., J. B. Lippincott Co., 1921. 310 pp., illus., 8 x 5 in., cloth. $3.75.

This book is intended as an exhaustively and systematically classified record of the developments and progress in the application of oil fuel for all steam raising, metallurgical and other purposes, except internal combustion engines, for which liquid fuel can be used successfully. The present edition has been thoroughly revised and much enlarged.

The Open Hearth; its Relation to the Steel Industry, Its Design and Operation.

First edition. Cleveland, O., The Wellman-Seaver-Morgan Co., 1920. 378 pp., illus., 11 x 9 in., cloth. $7.50. (Sold by U. P. C. Book Co., Inc., N. Y.)

This is a practical book on the design and construction of the open-hearth furnace, and on its use in modern steel-making. The methods of working, the gas producers, metal mixers, charging machines and other auxiliaries are described, so that the volumes form a complete, though brief account of open-hearth practise, very fully illustrated by drawings, half-tones and tables of data.

Personnel Relations in Industry.

By A. M. Simons. N. Y., The Ronald Press Co., 1921. 341 pp., 9 x 6 in., cloth. $3.00.

The first part of this work gives a survey of the situation in American industry and analyzes the elements of the employment problem. The specific stages through which the questions at issue have passed are then reviewed after which the author summarizes the best recent thought on the broad question of democracy in industry. Throughout the author has tried to call attention to the scientific laws that have emerged from recent study of the subject and to determine the reactions of human nature to the conditions presented in the various industrial problems.

Die Praktische Nutzanwendung der Prufung des Eisens Durch Atzverfahren und mit Hilfe des Mikroskopes.

By E. Preuss. Zweite auflage. Berlin, Julius Springer, 1921. 124 pp., illus., 9 x 6 in., paper. 14 M.

The present book is intended as a guide in the practical use of microscopic methods of testing the quality of iron, of sufficient scope to meet the ordinary needs of steel-works metallurgists and testing engineers. The methods of etching and polishing are given and the useful tests for determining structure, controlling heating, tempering, etc., are described.

Rayons X et Structure Cristalline.

By W. H. Bragg and W. L. Bragg. Translated from the third English edition. Paris, Gauthier-Villars et Cie, 1921. 209 pp., illus., 9 x 6 in., paper, 12 fr.

The work here presented in translation is an interesting and valuable account of the recently introduced method of investigating crystals by x-rays, a method that has not only thrown light on crystalline structure, but also on the nature of x-rays themselves. The authors describe their methods, their researches upon the diffraction of x-rays and the most notable results obtained.

Relativity, The Electron Theory and Gravitation.

By E. Cunningham. Second edition. London and N. Y., Longmans, Green and Co., 1921, 148 pp., 9 x 6 in., cloth. $3.50.

The primary purpose of this monograph was to set out as clearly and simply as possible the relation of the principle of relativity to the electron theory, in a way useful to the general reader and especially to the experimental physicist. In the present edition a second section has been added, which presents the general principle in its present form.

Small Motors, Transformers, Electromagnets.

By H. M. Stoller, F. E. Austin, E. W. Seeger. Chicago, American Technical Society, 1920. 320 pp., illus., 8 x 6 in., cloth. $3.00.

The first section of this book discusses small motors, automobile starting motors and charging generators and farm lighting outfits. The practise of the Western Electric Company in designing small motors is described, and instruction is given in rewinding small direct and alternating-current motors to change their characteristics. Typical designs are given for d-c. motors of all standard voltages, ranging from 0.01 h. p. to 0.5 h. p. in size, and for a-c. induction motors from 0.125 to 0.5 h. p. in size.

The second section, on small low-tension and high-tension transformers, treats of those which will transform from 110 to 220 volts and down to the lower voltages. The instruments described include a 10,000-volt, a 2,200-volt, a 10-volt, and a 22-volt transformer.

The concluding section includes typical designs of electromagnets for direct and alternating-current work and induction coils. Flat-plunger, cone-plunger, horseshoe and clapper electromagnets and portative magnets are considered.

La Theorie de la Relativite Restreinte et Generalisee.

By A. Einstein. Paris, Gauthier-Villars, et Cie., 1921. 120 pp., 7 x 5 in., paper. 7 fr.

This French edition of Dr. Einstein's popular presentation of the theory of relativity is based on the second German edition. A lengthy preface by Emile Borel discusses the value of the theory and the limits of its practical use.

Die Transformatoren.

By Milan Vidmar. Berlin, Julius Springer, 1921. 702 pp., illus., 10 x 6 in., paper. 110 M.

Contents:—Der Eisenkern.—Die Wicklungen.—Das Gestell des Transformators.—Die Erwarmung des Transformators.—Die Probleme des Transformatorenbaues.—Der Preis und der Wirkungsgrad.—Der Preis und die Hauptabmessungen.—Der

Kleintransformator. Der Trockentransformator. Der Öltransformator.—Der Grosstransformator mit Wasserkuhlung.—Die Parallelschaltung von Transformatoren.— Das Transformieren der Phasenzahl.—Die Messungen des Transformatorenbaues.

This extensive treatise discusses the theory and practise of transformer construction, on the basis of many years experience. Numerous examples, taken from actual installation, are included.

UNITED STATES STEEL: A CORPORATION WITH A SOUL. By Arundel Cotter. Garden City, N. Y., Doubleday, Page and Co., 1921. 312 pp., ports., plates, 8 x 6 in., cloth. $3.00.

This is an enlarged and modernized edition of "The Authentic History of the United States Steel Corporation." It gives a well-written account of the reasons for its organization, its history, activities, aims and policies, relations with its employees, together with some account of important officials, past and present.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—May 25, 1921. Paper: "Light and Shade." Author: Mr. A. L. Powell, Edison Lamp Works of the General Electric Company. The talk was illustrated with a series of lantern slides showing examples of illumination. Attendance 25.

Baltimore.—May 20, 1921, Engineers Club. Mr. J. T. Corrin, of the Pittsburgh Transformer Company, presented a paper dealing with the recent developments in the design and manufacture of transformers. A number of pictures of transformers of the different types manufactured by the Pittsburgh Transformer Company were shown. Attendance 125.

Boston.—May 24, 1921, Auditorium, Engineers Club. Business meeting and election of officers as follows: Chairman, Lewis W. Abbott; Vice-Chairman, Edward L. Moreland; Secretary, F. S. Dellenbaugh, Jr.; Treasurer, Ira M. Cushing. After all business had been disposed of a social meeting took place during which refreshments were served. Attendance 140.

Chicago.—May 26, 1921, Congress Hotel. Meeting held in conjunction with Power Section of the A. S. M. E. Subjects: "Location and Distribution of Central Station Power in the Middle West" by Mr. W. L. Abbott, Commonwealth Edison Company; and "Power Production and Use" by Mr. C. W. Place, General Electric Company. Attendance 300.

Cincinnati.—May 12, 1921, Assembly Hall, Union Gas & Electric Company. Subject: "Cost of Electric Service in View of Present Economic Trend." Speaker: Mr. P. M. Lincoln, Lincoln Electric Company. Attendance 25.

June 9, Cincinnati Country Club. Business meeting and election of officers as follows: Chairman, J. D. Lyon; Secretary-Treasurer, Leo Schirtzinger; Executive Committee, Messrs. A. M. Wilson, C. W. DeForest and Wm. S. Culver. The Chairman called on various members for short talks. Attendance 30.

Connecticut.—May 13, 1921, Lampson Lyceum, Yale University. Paper: "Preservation and Utilization of Niagara Falls." Author: Mr. John L. Harper, Vice-President and Chief Engineer, Niagara Falls Power Company. The paper was illustrated by lantern slides and moving pictures. Attendance 225.

Denver.—May 21, 1921, Gas & Electric Company's Assembly Hall. Annual meeting and election of officers as follows: Chairman, Burton C. J. Wheatlake; Vice-Chairman, Edward A. Phinney; Secretary-Treasurer, Robert B. Bonney. The Chairman then introduced Professor L. D. Crain, of the Colorado Agricultural College, who spoke very interestingly and instructively on the subject of Electricity and Machinery on the Farm. Attendance 15.

Indianapolis-Lafayette.—May 27, 1921. Subject: "Inductive Interference." Speaker: Professor R. V. Achatz, of Purdue University. Attendance 55.

Ithaca.—May 6, 1921, Franklin Hall. Subject: "Alternating-Current Automatic Block Signaling." Speaker: Mr. S. M. Day, of the General Railway Signal Company. Attendance 50.

Madison.—April 27, 1921, Engineering Building, University of Wisconsin. Subject: "Problems in Connection with Extending Electric Service to Prospective Consumers." Speaker: Mr. J. N. Cadby. Attendance 30.

May 26, 1921, Engineering Building, University of Wisconsin. Election of Mr. C. B. Hayden as Chairman for 1921-22. Subject: "The Maintenance and Operation of High-Voltage Lines." Speaker: Mr. E. J. Kallevang, of the Wisconsin Power, Light and Heat Company. Attendance 20.

Minnesota.—April 29, 1921, Elks Club, St. Paul. Dinner followed by a talk by Mr. R. A. Lundquist, U. S. Department of Commerce, on his investigation of electrical trade conditions in the Orient and Africa. After the meeting an inspection trip was made of the St. Paul Gas Company's automatic substation for light and power in the Hamm Building. Attendance 50.

Pittsburgh.—May 10, 1921, William Penn Hotel. Subject: "Protective Relays." Speaker: Mr. L. N. Crichton, of the Westinghouse Electric & Manufacturing Company. The talk was illustrated by lantern slides and experimental tests on relays, and was devoted to the use of relays in securing continuity of service in power systems. Attendance 125.

Pittsfield.—May 31, 1921, General Electric Company's Auditorium. Smoker, during which District Attorney Charles H. Wright spoke on "Personal Rights Under the Constitution." Refreshments were served. Attendance 210.

Providence.—June 10, 1921, Providence Engineering Society Rooms. Annual meeting and election of officers for 1921-22 as follows: Chairman, Nicholas Stahl; Vice-Chairman, F. C. Freeman; Secretary-Treasurer, F. N. Tompkins. The new Chairmen, Mr. Nicholas Stahl, gave a very interesting and instructive talk on "Experiences in the Burning of Fuel Oil." Much of the subject matter pertained to the methods and apparatus used at the Narragansett Electric Lighting Company Station, one of the largest oil-burning stations in the East. Attendance 50.

St. Louis.—May 25, 1921, Engineers' Club. Business meeting, followed by a talk by Mr. W. F. Gaphart, of the School of Commerce, Washington University, on "Financing Public Utilities." Attendance 47.

San Francisco.—April 29, 1921. Subject: "A Variable Voltage Railway Converter Substation." Speaker: Mr. J. E. Woodbridge. Attendance 140.

Schenectady.—May 20, 1921, Edison Club Hall. Subject: "Engineering as Applied to Investments." Speaker: Mr. R. J. McClelland, Investment Banker, New York City. Attendance 155.

Seattle.—May 17, 1921, Arctic Club Assembly. Business meeting and election of officers as follows: Chairman, Mr. J. P. Growdon; Secretary, Mr. E. S. Code. Mr. R. F. Wensley, of the Westinghouse Elec. & Mfg. Co., gave a very interesting talk on "Automatic Substations as Applied to Power Railway, Industrial and Mining Applications." The talk was illustrated by lantern slides showing the first automatic substation, more recent installations and diagrams of control equipment. Views were also shown of the automatic substation just completed for the Northwest Traction Company at Martha Lake. Attendance 95.

Toronto.—April 29, 1921, Physics Building, Toronto University. Subject: "Illumination." Speaker: Mr. W. D'A. Ryan, of the General Electric Company. The subject was divided into four principal parts: The History of Artificial Illumination, The Illumination of the Panama-Pacific Exposition, Spectacular and Pageant Lighting, and Intensive Street Lighting. The lecture was built up around a set of three hundred of what are probably the finest lantern slides ever projected in Toronto. Mr. Ryan expanded on the subject matter of the slides as they were shown, and gave very interesting data as to the intensities of illumination, the types of illuminants and the cost of installation. Attendance 350.

May 13, 1921, Engineers' Club. Business meeting and election of officers as follows: Chairman, W. P. Dobson; Secretary, P. A. Borden; Executive Committee, Messrs. Schwenger, Chubbuck, Leacock, Anderson, Fleming and Henderson. After the business of the evening a short informal talk on the Queenston Chippawa Development of the Hydroelectric Power Commission was given by Mr. E. T. J. Brandon. The talk was liberally illustrated and served to give those present a very clear idea of this great work. Attendance 83.

Urbana.—May 18, 1921. Business meeting and election of officers for 1921-22 as follows: Chairman, E. H. Waldo; Vice-Chairman, C. L. Conrad; Secretary-Treasurer, H. A. Brown. Attendance 17.

Utah.—May 27, 1921, Commercial Club. Election of officers for 1921-22 as follows: Chairman, Paul P. Ashworth; Secretary, C. R. Higson; Junior Past Chairman, J. F. Merrill; Executive Committee, Messrs. H. W. Clark, J. A. Kahn, Robert Miller and W. A. Moser. Subjects: "Outline of Einstein Theory" by Dr. Orin Tugman, of the University of Utah; "Bonneville Irrigation Project" by Mr. O. McDerwith. Attendance 55.

Vancouver.—April 15, 1921. Subject: "High-Tension Transmission in British Columbia." Speaker: Mr. J. Muirhead, Inspector of Electrical Energy for the Province of British Columbia. Attendance 27.

May 6, 1921. Subject: "Electrical Power in Pulp and Paper Mills." Speaker: Mr. T. H. Crosby. Attendance 26.

Worcester.—May 10, 1921, Worcester Tech. Subject: "Modern Photography." Speaker: Mr. Arthur Palme. The lecture was illustrated with seventy slides, twenty of which were in natural colors. A one-reel film entitled "Revelations" showing the history of X-Rays and some actual X-Ray Motion Pictures concluded the lecture. Attendance 155.

PAST BRANCH MEETINGS

Armour Institute of Technology.—May 20, 1921. Election of officers as follows: Chairman, Robert P. Burns; Secretary, L. C. Grube; Treasurer, Eugene Mueser. Attendance 22.

University of Cincinnati.—May 24, 1921. Subject: "Ball Bearings." Speaker: Mr. A. A. Van Pelt, E. E. Attendance 86.

Clemson College.—May 10, 1921. Subject: "Troubles on the High-Voltage Lines." Treated by: Messrs. Fowler, Gower and Miley. "Current Events" by Mr. W. P. Tyler. Attendance 52.

University of Colorado.—May 12, 1921. Election of officers for 1921-22 as follows: Chairman, T. D. Sylvester; Secretary, F. D. Doolittle; Treasurer, Ivan Mauntel; Junior Committee, Messrs. Keller and Rankin. Professor W. C. Du Vall spoke on "History and Development of the A. I. E. E." Attendance 28.

Iowa State College.—May 11, 1921. Subject: "Electrical Slide Rules and Short Cuts in Electrical Computations." Speaker: Professor Edwin Kurtz. Advertising calculators and graphical charts were distributed and their use explained. Attendance 59.

May 25, 1921. Subject: "Fan Design and the Industrial Application of Air." Speaker: Mr. J. H. O'Brien, District Manager, for the American Blower Company, Indianapolis. Attendance 25.

June 1, 1921. Smoker. Professors Paine and Kurtz gave short talks. Mr. L. V. Bryan, Senior student, spoke on "Leaving School as a Senior." Messrs. Martin, Wilkins, Jeffers, Brown and Edaburn, Junior students. gave a mock faculty meeting of the Electrical Engineering Faculty. Refreshments were served. Attendance 93.

University of Iowa.—May 2, 1921. Talks were given by Mr. W. Reilly on "Einstein Theory" and Mr. W. C. Brandes on "Testing of Watthour Meters." Attendance 28.

May 6, 1921. Joint meeting of the various engineering branches. Subject: "Steam Power Plants." Speaker: Professor Fleming. Attendance 75.

May 16, 1921. Subjects: "Electrification of Railroads" by Mr. H. Shore; "Engineering in Foreign Countries" by Mr. V. Varbedian; "Power Distribution" by L. Rohret. Attendance 30.

Kansas State College.—April 25, 1921. Subjects: "Organization of the Commonwealth Edison Company" by Mr. M. C. Watkins; and "The Size, Movement and Force of Electrons" by Professor J. L. Brennenman. Attendance 30.

May 9, 1921. Subject: "Automatic Signal from a Railway Fireman's Viewpoint." Speaker: Mr. R. M. Crow. Attendance 14.

May 23, 1921. Subject: "Publicity Utility Investments." Speaker: Mr. Arthur Groesbeck, of the Rocky Ford Milling & Power. Attendance 31.

Lehigh University.—May 16, 1921. Election of officers as follows: Chairman, E. F. DeTurk; Vice-Chairman, G .M. Brumbaugh; Secretary, W. F. Tait; Treasurer, E. H. Snyder. Subject: "Recent Practise in Telephone Construction." Speaker: Mr. Frederick Galbraith, of the A. T. &. T. Co. Attendance 41.

University of Maine.—May 17, 1921. Subject: "Development of the Automatic Substation." Speaker: W. C. Plummer, President of the Branch. Attendance 9.

Massachusetts Institute of Technology.—May 17, 1921. Banquet. Election of officers for 1921-22 as follows: Chairman, L. R. Culver; Vice-Chairman, A. W. Milliken; Secretary, T. W. Codding; Treasurer, C. L. Maltby. Mr. C. T. Edgar, President, Boston Edison Company, spoke on the new coastwise superpower line; Dr. Elihu Thomson spoke on lightning phenomena and the Aurora Borealis. Attendance 100.

University of Michigan.—May 16, 1921. Election of officers for 1921-22 as follows: Chairman, F. D. Johnston; Vice-Chairman, W. E. Cook; Secretary, A. J. Martin; Treasurer E. W. Folsom. Attendance 11.

May 24, 1921. Mr. H. P. Schienberg, of the Western Electric Company, gave the talk of the evening, which covered the production of line poles and crossarms and was illustrated by six reels of moving pictures. The pictures were taken in the northwestern part of the country. This was a joint meeting with the Forestry Students. Attendance 77.

Montana State College.—May 11, 1921. Lecture by Mr. A. D. Stewart on Westinghouse activities. Attendance 48.

May 13, 1921. Electrical show. Attendance 908.

May 18, 1921. Moving pictures, Westinghouse films. Attendance 409.

University of North Carolina.—May 27, 1921. Election of officers as follows: Chairman, R. M. Casper; Vice-Chairman, C. U. Smith; Secretary, R. G. Koontz; Treasurer, J. R. Pursur, Jr. Attendance 48.

Ohio Northern University.—May 9, 1921. Election of officers as follows: Chairman, L. A. Kille; Vice-Chairman, H. D. Farnsworth; Secretary, I. W. Knapp; Treasurer, D. J. Wolfe. Talks by the Professors. Refreshments were served. Attendance 38.

Ohio State University.—May 20, 1921. Illustrated lecture on "Industrial Control Devices" prepared by the General Electric Company. Attendance 20.

University of Oklahoma.—May 18, 1921. Election of officers as follows: Chairman, Wesley Seifert; Vice-Chairman, Cecil Roush; Secretary, H. V. Thornton; Treasurer, A. B. Munson; Reporter, Virgin Pendleton. Attendance 53.

Oregon State College.—May 5, 1921. Election of officers for 1921-22 as follows: Chairman, Walter D. Olson; Vice-Chairman, Geo. Drewitt; Secretary-Treasurer, Clinton T. Hurd; Publicity Manager, Sidney Caldwell. Three reels of motion pictures entitled "The Benefactor" were shown after the meeting. Attendance 29.

Purdue University.—May 10, 1921. Election of officers for 1921-22 as follows: Chairman, N. C. Pearcy; Vice-Chairman, C. R. Hanna; Secretary, F. R. Finehout; Treasurer, S. J. Spurgeon. A six reel film on the manufacture of wood poles and wood conduit was shown. Attendance 44.

May 18, 1921. Mr. M. A. Putt, of the General Electric Company, gave a talk and demonstration of the "Pyrotip." Attendance 32.

Virginia Military Institute.—May 24, 1921. Subject: "Manufacture of the Mazda Lamp and Production of Artificial Light," with a Lighting Display. Speaker: Mr. J. G. Henninger of the Fostoria Sales Division National Lamp Works General Electric Company. Attendance 73.

University of Virginia.—May 11, 1921. Election of officers for 1921-22 as follows: Chairman, M. M. H. Morgan; Secretary-Treasurer, Mr. G. L. Goudy; Program Committee, Professor Rodman and Messrs. Forrest, Wingfield. Attendance 25.

State College of Washington.—May 13, 1921. Subject: "Electrical Measurements in Superheated Steam Research." Speaker: Professor A. R. Nottingham. Attendance 21.

University of Washington.—May 10, 1921. Subject: "Diesel Engines." Speaker: Mr. George S. Wilson. Attendance 28.

West Virginia University.—May 16, 1921. Subjects: "Hydroelectric Power for Industrial Purposes" by R. M. Hanks; "Repairing and Rewinding Armatures" by J. and L. Hark; "The Development of Radio Telegraphy" by A. C. Price; "The Vacuum Tube as a Generator" by W. D. Stump. Attendance 15.

University of Wisconsin.—May 3, 1921. Subject: "Signal Communication Methods." Speaker: Mr. C. T. Schrage. Attendance 18.

May 18, 1921. Business meeting, followed by a paper on "Electric Ship Propulsion," read by E. D. Johnson. Attendance 22.

May 25, 1921. Election of officers for 1921-22 as follows: Chairman, R. H. Herrick; Secretary-Treasurer, H. L. Rusch. Attendance 12.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

MEN AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y., the employment clearing house of the Societies constituting the Federated American Engineering Societies.

Notices for the JOURNAL are not acknowledged by personal letter, but they will usually appear in the next issue that goes to press.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to EMPLOYMENT SERVICE, as above.

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

OPPORTUNITIES

RECENT GRADUATES in Engineering Courses. Location New York City. X-564.

GRADUATE ELECTRICAL ENGINEER between 30-40 years. Should have gas and street R. R. experience as well as power sales. Location New York State. X-576.

YOUNG MAN acquainted with the electrical trade in New England to solicit business for repairing and recalibrating meters. Location Mass. X-590.

RECENT TECHNICAL GRADUATE for instructor in Electrical Engineering. Opportunity to pursue graduate work. Give references and details regarding technical and personal qualifications. X-596.

EASTERN TECHNICAL SCHOOL has opening on its teaching staff for instructor in Physics and Elementary Electricity. Young man, graduate of a four year Electrical or Mechanical Engineering Course with some practical or teaching experience preferred. The opportunity for advancement excellent. Reply stating age, education and training, experience and salary desired. Location Boston, Mass. X-604.

ENGINEER who has had experience in operating stationary oil engines, preferably the De La Vergne type. Prefer a single man. Location South America. X-613.

EASTERN TECHNICAL SCHOOL has opening for instructor in electrical machinery laboratory. Young men, graduates of a four years electrical or mechanical engineering course with some practical or teaching experience preferred. Opportunity for advancement excellent. Reply stating age, education and training, experience and salary desired. Location Boston, Mass. X-622.

ASSOCIATE PROFESSOR, or professor of electrical engineering, who will be responsible for laboratory courses handling about sixty juniors and fifteen seniors in a well developed laboratory. Should be prepared also to teach fundamental courses in direct currents and introductory alternating currents. Must be a man with both teaching and practical experience; a man with experience in a first class college laboratory is necessary. Location North West. X-628.

INSTRUCTOR in electrical engineering to handle, principally, laboratory courses. Must have had experience as an assistant, or instructor, in a good laboratory. Additional testing experience with a manufacturing company is desirable. Location North West. X-629.

INSTRUCTOR to serve in steam, gas and material testing laboratories. Should be a man of some experience in a good mechanical engineering laboratory. Location North West. X-630.

ASSISTANT PROFESSORS OF ENGINEERING DRAWING in a well-established State and Federal supported polytechnic institute wanted. Applicant must be thoroughly competent to teach any or all of the subjects dealt with in French's Engineering Drawing. Assurance of promotion to full professorship to properly qualified men. Location South. X-632.

DESIGNER of induction motors (not fractional horsepower) and familiar with their applications and manufacture for a successful

medium-sized company at present manufacturing electrical machinery. Both experience and initiative required. Position is attractive and permanent. In framing application, please state in detail character and extent of engineering, manufacturing, and commercial knowledge in relation to induction motors. Location New York. X-633.

SALES ENGINEERS. Must have good personality and know architects and builders in these localities. Elevator experience desirable. Application by letter only. Position will be open in two months. Location New York City and Middle West. X-637.

YOUNG PROGRESSIVE ENGINEER with some experience in design of air and oil-brake types of circuit breakers. Location Penna. Application by letter. X-638.

SALESMAN. In sales Department of old established manufacturing concern man about thirty to thirty-five years of age. One with engineering and sales experience preferred, to operate from Chicago office traveling the state of Wisconsin and the city of Chicago, about half time in each. Answer with complete details, including salary desired. X-643.

SALES. In Chicago branch of a substantial New York manufacturing concern, young man about 27 to 30 years of age, college trained preferred. A year or two successful sales experience would be additional qualification. Territory to be covered will be city of Chicago and some outside territory. Will be patient with the right man while he is learning. Please reply with full details as to education, experience and salary desired. X-644.

PROFESSIONAL DRAFTSMEN graduates of reputable engineering institutions who have had not less than five years work in the drafting rooms of large manufacturing concerns for university in South. X-647.

TECHNICAL GRADUATE who believes he could sell advertising. Prefer man who has been identified with the activities of a college, for example, in managing or assisting in the management of one of the teams or societies. Location New York City. X-652.

ELECTRICAL DRAFTSMEN, 5 or 6, in connection with preparing plans and specifications for various classes of electrical installations. Majority of the work will consist of electric hoist installations both induction motor and d-c. motor drive; power plant; transmission line and substation installations and in some instances electric pumping. Location Pa. X-654.

ELECTRICAL CONTRACTING COMPANY, well established, doing mostly public and factory work, desires thoroughly capable and experienced man to act as job foreman on construction work for a time with the idea of becoming general foreman later on, if found possessed of requisite ability. Splendid opportunity for right man. Technical graduate preferred, but man without college education will be considered. Location near New York City. X-655.

INDUSTRIAL ENGINEER to be in charge of large boiler shop. Must have boiler shop experience. Must be diplomatic, tactful, and a good executive. Application by letter only. Only engineer with broad experience will be considered. X-659.

MEN AVAILABLE

GRADUATE ELECTRICAL ENGINEER of 1917, desires work in field of electrical engineering, telephony or radio. Has had approximately one year's experience in each. Desires permanent work with a good chance for advancement. Single. Prefer Middle West. Available early in July. E-2733.

CHIEF OPERATING ENGINEER or mechanical superintendent with broad experience in safe and economical operation, maintenance of electric light, power and refrigerating plants; also large factories and buildings having 1st class engineers and electrician licenses. At present holding similar position, desires to make a change location anywhere before August 1st. E-2734.

MECHANICAL ENGINEER, age 22; single, graduate Stevens Institute of Technology, having about two years varied electrical experience, desires position in electrical engineering work preferably with consulting electrical engineering or electrical contracting concern, located near New York City where individual merit will be rewarded by advancement. Available in about two weeks notice. E-2735.

ELECTRICAL ENGINEER, age 36; seven years assistant professor of electrical engineering in prominent technical school in New York; very broad experience including isolated power plant management, testing and designing of electrical machinery, "radio" work, power distribution. Member A. I. E. E., salary $4000. E-2736.

GRADUATE ELECTRICAL ENGINEER, eleven years commercial, engineering and sales experience, available at once. Has been in executive charge of large engineering department of public utility. Has also been sales engineer. Responsible executive engineering or business position desired; preferably Central States. E-2737.

MECHANICAL ELECTRICAL, practical and executive engineer. Inventive ability, twenty-five years practical and executive experience with mining, marine, estate, steam, diesel, gas, oil, cars, refrigeration, oxyacetylene, plumbing, heating, ventilation, compressing. Experienced in every branch of trade from designing to operating. Secondary and technical education. Available 14 days notice. Offers solicited. E-2738.

ELECTRICAL ENGINEER, seven years experience in general engineering and seven years on design of small and medium sized d-c. and a-c. motors and generators, some teaching experience. Desires position as consulting or designing engineer. Developed motors and generators for nearly all industrial applications. Can furnish references showing high grade mathematical and analytical ability. Will consider teaching, electrical engineering or mathematics. E-2739.

RESEARCH ENGINEER, six years experience in electrical and mechanical laboratory research and development, including fifteen months development and service work on automobiles and equipment. Now employed. College graduate, 1915. Associate A. I. E. E. Available on short notice. Eastern States preferred. E-2740.

ERECTING ENGINEER, age 38; twelve years experience in erection and maintenance of steam and hydroelectric machinery and equipment, in connection with power, mines and mills in the States, Alaska, and foreign countries, desires connection as erecting and maintenance engineer on hydroelectric equipment. No objection to foreign work. E-2741.

ELECTRICAL ENGINEER, graduate Univ. of Mich. Associate A. I. E. E. Eight years experience covering construction, operation and maintenance of high-tension generating stations, substations, installation of factory equipment and a year of G. E. test, wishes responsible position with engineering, manufacturing or light and power company. Location U S. A. or abroad. E-2742.

ELECTRICAL ENGINEER. Age 24; married. Six years experience in practical and technical engineering. Two years experience hydroelectric engineering. Four years experience electrical testing, wiring, operating, installation of power panels and all kinds of electrical repairing. Best references. Assoc. A. I. E. E. Available immediately. Not looking for large salary. E-2743.

ENGINEER AND EXECUTIVE. Fourteen years practical experience in the design, construction and operation of engineering structures and industrial plants, holding positions as general superintendent, and engineer of works. Technical graduate mechanical engineering, 1907, desires position requiring high ability and hard work but offering opportunity for advancement. E-2744.

GRADUATE ELECTRICAL ENGINEER, age 25; married. Desires connection with concern where native ability, initiative and hard work will be appreciated. Three and a half years experience on machine layout, transmission and substation design. Salary of secondary importance. Employed at present. E-2745.

ELECTRICAL ENGINEER, age 36; single. Ten years experience in power station design, construction, operation and industrial engineering. Assoc. A. I. E. E. Extensive executive and purchasing experience. Desirous of entering engineering sales field or executive position. Salary $3500-5000. Available at once. E-2746.

ELECTRICAL LABORATORY ENGINEER. Twelve years experience in electrical and magnetic measurements and research work in laboratories of several of largest electrical companies, including General Electric, desires responsible position where technical knowledge on these subjects is essential. Age 34; present salary $2600; eastern location preferred. E-2747.

GRADUATE ELECTRICAL ENGINEER, age 37; having been in charge of the transmission and distribution systems of large Eastern Railway, now open for position in above mentioned line, or as manufacturers' salesman. E-2748.

ELECTRICAL MECHANICAL INDUSTRIAL and designing engineer; age 42; university graduate; able executive. Fifteen years, shop, office and field experience, with large industrial engineering and manufacturing companies; in estimating, engineering economics, design, construction and equipment of power plants, substations and factories. Salary in proportion to responsibilities. E-2749.

ELECTRICAL ENGINEER. American; age 33. Technical graduate 1911. Electrical manufactory testing, engineering and commerical experience. Several years practical work on installation, operation and maintenance of heavy traction equipment steam railroad electrification. Services as engineer offered at reasonable rate on new projects of this nature. E-2750.

GRADUATE ELECTRICAL ENGINEER, age 27; married. One year with large electric railway and light company, one year business experience. Desires position with engineering, manufacturing or light and power company. Assoc. A. I. E. E. E-2751.

INDUSTRIAL ENGINEER, technical, mechanical, electrical engineer, experienced in factory organization, operation, management. Modern methods of production control (routing, planning, scheduling), storeskeeping, determination, cost systems. Extensive practical experience as production manager of factories using methods employed by Messrs. Gantt, Barth, Baker and Taylor. Completing systematizing plant employing 3000; capacity production manager. E-2752.

EXECUTIVE ENGINEER, Member A. I. E. E. Yale graduate, desires interview with house of recognized reputation in Philadelphia, New York or New England. Eleven years experience covering broad field, in charge of electrical design and construction, and general building work. Several years training in all phases of operating. Age 31, married. E-2753.

ELECTRICAL ESTIMATOR AND ENGINEER, technical education. Fourteen years experience in building construction as mechanic, foreman, draftsman, engineer, and electrical estimator. Member of Chicago Electrical Estimators Association, Assoc. A. I. E. E. E-2754.

ENGINEER, B. S. in E. E. Associate A. I. E. E. age 25; single. Desires position in engineering or operation department. One year G. E. test, two years general engineering, tests, installations, and data. Present employed. Available after July 31st. E-2755.

ELECTRICAL ENGINEER, age 23; single; graduate California Inst. of Technology, 1920. One year's experience on General Elec. Co. test. Desires position with engineering, manufacturing or power company with opportunity for experience and advancement, or would like position as instructor in electrical engineering at some technical college. Available on short notice. Location immaterial. E-2756.

ELECTRICAL ENGINEER, Graduate Penn. State College; age 24; married. Desires connection with engineering, manufacturing or light and power company, where a hard working young man may be assured advancement. About nine months experience. Location preferably Pennsylvania. Available Sept. 1st. Member A. I. E. E. E-2757.

MECHANICAL AND POWER ENGINEER, age 29; single, technical graduate, B. S. and M. E. Seven years experience along broad lines, chemical manufacturing, machine shop metallurgy, sugar engineering, industrial and power plant practise, operation, layout, design, calculations, steam, water, air heating and distribution, research, etc. Has business and executive ability and can handle men; desires connection as mechanical engineer or in similar responsible position. E-2758.

TECHNICAL GRADUATE, B. S. degree in electrical engineering; age 22; single, desires connection with engineering, manufacturing or power company. One year's commercial and one year's technical experience. Work along commercial lines considered. Member A. I. E. E. Available immediately. E-2759.

ELECTRICAL AND MECHANICAL ENGINEER and executive, eighteen years experience in design, construction and operation of power plants and substation equipments, desires change. Age 42; married. Present salary $4100. Member A. S. M. E.; Assoc. A. I. E. E. E-2760.

ELECTRICAL ENGINEER, Assoc. A. I. E. E age 31, twelve years experience in engineering and construction, covering responsibility of supervising estimating, and laying out work, desires position affording opportunity in this field. E-2761.

ELECTRICAL ENGINEER, technical graduate; age 27; three years experience with large electrical concern in development and design of small motors of the splitphase, repulsion-induction polyphase, and two-pole d-c. types. Familiar with small motor application. Desires position with concern in which one can develop with the concern and where there would be excellent opportunities for the right man. Assoc. A. I. E. E. E-2762.

PROFESSOR OF ELECTRICAL ENGINEERING at State Institution desires change. Writer on technical subjects and practical engineer. E-2763.

ELECTRICAL ENGINEER, sixteen years experience with consulting engineer, with manufacturing concern and with Navy, desires part time work for consulting engineer or patent attorney. Designs, reports, experimental work. Capable of turning out careful and accurate work. Location in or near New York City. E-2764.

ELECTRICAL ENGINEER, age 36; seven years assistant professor of electrical engineering in prominent technical school in New York; very broad experience including isolated power plant management, testing and designing of electrical machinery, "radio" work, power distribution. Member A. I. E. E. Would like teaching position. Salary $3600. E-2765.

ELECTRICAL ENGINEER technical graduate; age 29; single. Two years practical experience in testing and layout work of starting and lighting systems for automobiles, also two years experience in export of machinery. Speaks and writes Greek and French. Assoc. A. I. E. E. Interested in estimating and contracting work also in installation of electrical machinery. Available immediately. E-2766.

TECHNICAL GRADUATE, B. S. in E. E. age 24. Three years testing and maintenance experience. Desires position with chance for advancement. Preferred location; central states. Available immediately. E-2767.

ASSOCIATE ELECTRICAL ENGINEER, Bureau of Standards, engaged for ten years in laboratory and field research and in dealing with public utility officials concerning electrolysis, desires responsible position with college of public utility. Several years college teaching experience and as engineer for G. E., W. E. and N. Y. Telephone Companies. E-2768.

ELECTRICAL ENGINEER. Nine years practise with sales experience, familiar with New York trade, desires to represent manufacturer of electrical or mechanical product in New York City. E-2854.

GRADUATE ELECTRICAL ENGINEER. Seventeen years' practical experience in manufacturing work and three years at teaching. Member A. I. E. E. Will consider teaching in central West or West at reasonable price. E-2859.

ELECTRICAL AND EXECUTIVE ENGINEER. Age 33; M. E. degree. Two years G. E. test and eight years in construction and operation of transmission lines, distribution systems, power plant, industrial installations, steam apparatus and piping. Experienced in handling men, organizing, purchasing, correspondence and writing reports and specifications. Position desired assistant manager, superintendent of operation or construction with power company or engineering capacity with industrial concern. E-2860.

ELECTRICAL ENGINEER. Age 27, experienced in electric railway and industrial plant engineering and electrical installations aboard ships, desires position in either sales or engineering departments of concern offering good chance for advancement. Now in charge of design work (electrical) for freighters and tankers. Available on short notice. Salary $3000. E-2861.

ELECTRICAL SUPERINTENDENT, technical training, twelve years experience design and supervision of hydroelectric stations, transmission lines, industrial plants including mechanical and concrete construction. Past five years charge hydroelectric construction in Latin America. Thorough knowledge Spanish, executive ability, tactful, no labor conditions too difficult. References furnished. Nominal investment to guarantee permanency if required. American; married; age 35. Minimum $5000. Available Sept. 1921, or Jan. 1922. E-2862.

TEACHERS AVAILABLE

The following list gives in each case school attended, age, etc. For more complete information address the Employment Service Bureau, giving key number.

University of Illinois; Penn. State College; age 36; married. Desires to teach any electrical engineering subjects except wireless and telephony. E-2769.

University of Michican, age 40; married. Taught mechanical drawing. Location Middle West or East. E-2770.

University of Michigan B. A., M. I. T.—B. S. Age 54; married. Desires to teach theoretical and practical electricity. Locations preferred Far West or Northern Atlantic States. E-2771.

University of Illinois; age 42; married. Location Central States. Salary $5000. E-2772.

University of Wisconsin; age 49; married. Eighteen years experience teaching electrical engineering subjects. Location West or Middle West. E-2773.

Polytechnic Institute, Brooklyn; age 45; married. Six years teaching experience. Desires position as professor, assistant professor or associate professor. Location U. S., East, Central or West. E-2774.

Ohio State Univ. Age 35; married. Four years, teaching experience, instructor and assistant professor. Location Central States. E-2775.

University of Wisconsin; age 36; married. Six years teaching experience, instructor and associate professor. Minimum salary $3600. Location Middle West, North or West. E-2776.

University of Wisconsin; age 30; married. Five years teaching experience, instructor and associate professor. Location Middle West. E-2777.

University of Wisconsin; age 41; married. Fifteen years teaching experience, instructor, head of department of physics. Location North or West. E-2778.

Ohio State University. M. E. E. E. Harvard A. M. Age 35; married. Three years teaching experience, instructor and professor. E-2779.

Iowa State College, age 36; married. Taught physics, mechanical drawing, direct and alternating-current electricity, trigonometry. Location Middle West. E-2780.

University of Arkansas, Ohio State University; age 35; married. Ten years teaching experience. Assistant professor and professor. Taught dynamo machinery, illumination, electric railway. Location Middle West or West. E-2781.

University of Texas, age 28; married. Three years teaching experience. Location South or Pacific Coast. E-2782.

University of Minnesota, age 39; married. Four years teaching experience. Desires position as assistant professor. Location West. E-2783.

University of Illinois, age 38; married. Eleven years teaching experience, instructor, assistant professor, associate professor, and professor. Desires position as professor of electrical engineering. E-2784.

Rose Polytechnic Inst.; age 35; married. Three years teaching experience. Desires position assistant or associate professor. Location Central States. E-2785.

Syracuse University, age 32; single. Desires position as professor or head of E. E. department. E-2786.

Rensselear Polytechnic Institute, age 37; married. Four years teaching experience, desires position as professor of electrical engineering and physics. E-2787.

Cooper Institute, age 44; married. Three years teaching experience. Location East. E-2788.

University of Maine. Age 43; married. Seventeen years teaching experience. E-2789.

Central Technical College. Age 42; married. Thirteen years teaching experience Desires position as professor of electrical engineering. E-2790.

Union University. Age 40; married. Taught electrical engineering continuously since 1908. Location South or East. E-2791.

Swarthmore College, age 33; single. Desires position associate professor. E-2792.

Leeds University, age 53; married. Desires position as assistant professor. Salary $5000. Location Eastern states. E-2793.

Massachusetts Inst. of Technology, age 36; married. Seven years teaching experience. Desires position as professor or head of E. E. department. Location North East or South West. E-2794.

Rutgers, Columbia, age 45; married. Fifteen years teaching experience. Instructor, assistant professor, professor of physics. Desires position as head of department in small technical school of state university. E-2795.

Columbia University; age 31; married. Desires position as professor or assistant professor teaching mathematical physics, dynamics, mechanical and automotive engineering subjects, design, etc., Location East or Middle West. E-2796.

Kansas State Agricultural College; age 37; married. Desires to teach power station of electrical engineering. Location Middle West. E-2797.

Stevens Institute of Technology; age 27; single. Taught mechanical drawing two years. Location Ohio, Indiana, or New York. E-2798.

Drexel Institute; age 26; single. Taught electricity, a-c. and d-c., mechanics, strength of materials, mechanical laboratory, testing and electrical laboratory. Location Pennsylvania, New Jersey or New York. E-2799.

Milwaukee University, age 21; single. No teaching experience. Desires position as laboratory assistant. Location East or Middle West. E-2800.

University of Nebraska. Age 29; single; Taught drawing, descriptive geometry, electrical engineering. Location U. S. E-2801.

M. I. T., age 31; married. Taught elements of electrical engineering, electrical laboratory, industrial applications of electricity. Location Middle West. E-2802.

Lewis Institute, age 24; single. Taught physics. Location Middle West. E-2803.

Cornell University, Univ. of Colo.; age 27; single. Two years teaching experience. Location preferred, West. E-2804.

Rice Institute; age 28; single. No teaching experience. Location Eastern States. E-2805.

Iowa State College, age 30; married. Desires position as instructor in mechanics, electrical theory, testing laboratory. (Mech. or E. E.) Location U. S. E-2806.

Ohio State University, age 30; married. Desires teaching position. Location West. E-2807.

Worcester Polytechnic Institute, age 35. married. Four years teaching experience; electrical measurements, laboratory, theory of alternating-current circuits and machines. Desires position as professor or associate professor. Location New England, Eastern Canada. E-2808.

University of Illinois, age 30; single. Desires teaching position. Location North West or Canada. E-2809.

University of California; age 27; married. No teaching experience. Desires position as instructor in elementary electrical engineering, physics, mathematics, or laboratory instructor in electrical engineering, tests, physics or steam. Location Middle West or West. E-2810.

Rutgers College; age 25; single. Desires teaching position; physics, tests, inspection, design, electrical railway. Location preferred, California. E-2811.

Yale University, age 24; single. Desires to teach electrical or mechanical engineering or physics. Location New England. E-2812.

New York Trade School, age 26; single. Desires position as electrical instructor at technical or trade school. Location preferred near New York City. E-2813.

Pennsylvania State College; age 24; married. No teaching experience. Location Middle or Western States. E-2814.

Pennsylvaniat State College; age 33; married. Six years teaching experience. Location East. E-2815.

University of Kansas, age 45; married. Ten years teaching experience, instructor and professor. Desires position professor of electrical or mechanical engineering. Would consider Orient; particularly China. E-2816.

Transylvania College, Univ. Ky., age 41; married. Ten years teaching experience. Head of department of electrical engineering. E-2817.

Technical University of Carlsruhe; age 33; married. Taught electrical engineering and physics. E-2818.

Pennsylvania State College; age 35; married. Taught course in electricity (night school). Would consider $1800 for 9 months. Location New England or North Atlantic States. E-2819.

University of Colorado; age 27; married. Taught physics, chemistry, electricity and mathematics. Location vicinity of New York. E-2820.

Clarkson Tech. Age 30; married. Teaching experience in Army only. Desires to teach mathematics and E. E. E-2821.

Lehigh University, age 28; single. Taught power engineering, thermo-dynamics laboratory. Location New York, New Jersey and Pennsylvania. E-2822.

Lehigh University, age 38; married. Taught electrical, engineering physics, anal. mech. Location East or North. E-2823.

University of Kansas, age 39; single. Taught elementary electrical machinery, illumination and central station design. Location West. E-2824.

University of Michigan; age 29; single. Taught mathematics and physics. Prefer location Pennsylvania or Michigan. E-2825.

University of Washington; age 26; single. Desires to teach mathematics (algebra, trigonometry, calculas). E-2826.

Syracuse University; age 39; married. Electrical engineering subjects eleven years. E-2827.

Purdue University; three years. Age 29; single. Assistant instructor electrical measurements. Location near New York City. E-2828.

Cornell University; age 40; single. Taught direct and alternating-current machinery, power plant design, illumination, switching control and protection. Location near New York City. E-2829.

Drexel Institute; age 23; single. Taught electrical subjects. E-2830.

Pennsylvania State College; age 34; single. Taught electrical engineering subjects. E-2831.

Cornell University; age 33; married. Taught electrical power, laboratory and design. E-2832.

Cornell University; age 33; married. Taught electrical engineering, sales engineering, export practise. Desires evening work. Location near New York City. E-2833.

Lehigh University; age 24; single. Taught mathematics, english and civics. Desires to teach electrical subjects or physics. Location Middle or Eastern part of Pa., Atlantic Coast. E-2834.

Union College; age 24; single. Taught electrical laboratory, analytical geometry, calculas. Location Pacific Coast or vicinity New York City. E-2835.

Michigan Agricultural College; age 33; married. Desires to teach text book, or laboratory work in direct or alternating currents. Location Southern Atlantic States. E-2836.

McGill University; age 35; single. Taught electrical engineering subjects. Location near New York City. E-2837.

Worcester Polytechnic Institute; age 43; married. Taught design of electrical machinery, general courses in a-c. and d-c. theory, electrical engineering laboratory etc. Desires position as head of department, teaching electrical design and other E. E. subjects. Location Eastern or South Western States. E-2838.

Polytechnic Institute of Brooklyn; age 22; single. Have been assistant in physics department. Desire to teach mathematics, physics, electrical measurements, etc. E-2839.

Pennsylvania State College; age 24; single. Desires to teach electrical laboratory, design, radio theory. E-2840.

Virginia Polytechnic Institute; age 23; single. Desires to teach physics and electrical engineering subjects. Location immaterial. E-2841.

Purdue University; age 25; single. Taught electrical design, laboratory, and radio. Location Middle West. E-2842.

Bucknell University; age 23; single. Taught mechanical drawing, physics, algebra, trigonometry, plane or solid geometry, arithmetic, surveying. Location Eastern U. S. E-2843.

McGill University; age 35; single. Desires to teach mechanics, physics, electricity, electrical design, laboratory. Location West. E-2844.

University of Wisconsin; age 25; married. No teaching experience. Location Central or Western U. S. E-2845.

Michigan State College; age 25; single. No teaching experience. Location Michigan or bordering states. E-2846.

Highland Park College; age 32; married. Taught physics, laboratory, electrical construction and maintenance. Location North Central U. S. E-2847.

University of Texas; age 24; married. Taught mathematics, mechanical drawing, radio theory. Location United States. E-2848.

North Carolina State College; age 32; married. Location South or West. E-2849.

Lawrence College, University of Wisconsin; age 36; married. Taught electrical engineering. Six years practical engineering experience. E-2850.

University of Michigan; age 24; single. Taught electrical engineering; physics and radio. Location Middle or Far West. E-2851.

University of Kentucky; age 22; single. Laboratory instructor. Location South West Ohio, or Kentucky. E-2852.

Pennsylvania State College; age 23; single. No teaching experience. Location immaterial. E-2853.

University of Illinois; age 26; single. No teaching experience. Desires to teach electrical engineering subjects of physics. Location preferred Middle West or West. E-2855.

University of Michigan; age 26; single. Taught drawing (descriptive geometry) assistant. Location North Central States. E-2856.

Rice Institute; age 27; married. Taught elementary and advanced electrical engineering. Location immaterial. E-2857.

Leland Stanford, Jr.; Age 34; single. Taught electric testing, power plant, research. Interested only in positions as professor or associate professor. E-2858.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED JUNE 23, 1921

ACHESON, HARRY H., Plant Engineer, Bluefield Telephone Co., Bluefield, W. Va.

ADAMS, CHARLES H., Chief Electrical Engineer, Champion Engineering Co.; res., 222 E. Carmel St., Kenton, Ohio.

ADKERSON, BRANCH O., Student Engineer, American Tel. & Tel. Co., 1413 Hart Bldg., Atlanta, Ga.; Key West, Fla.

AHUJA, D. C., Asst. Electrical Engineer, Tata Iron & Steel Works, Jamshedpur, India.

ALBRECHT, EDWIN H., Chief Electrician, Independent Foundry Co.; res., 498 Patton Road, Portland, Ore.

ALM, EMIL, Professor of Electrical Engineering, (Electric Machine Design), Nya Tekniska Hogskolan, Stockholm, Sweden.

AMES, CHESTER E., Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston; res., 112 Washington Ave., Winthrop, Mass.

*ANDERSON, CLIFFORD N., Asst. Engineer, Standardizing Laboratory, General Electric Co., W. Lynn, Mass.; res. Scandinavia, Wis.

ANDERSON, O. W., General Storekeeper, West Penn System, Connellsville, Pa.

ANGLE, WESLEY M., Secretary, Stromberg-Carlson Telephone Mfg. Co., 1060 University Ave., Rochester, N. Y.

ARMITAGE, MELVILLE, Laboratory Engineering, Canadian General Electric Co.; res. 597 Bolivar St., Peterboro, Ont., Can.

AYRES, LEE T., System Dispatcher, Utah Power & Light Co., Terminal Substation, Salt Lake City, Utah.

BACHERT, HOMER A., Electrician, Inside Construction Dept., Pennsylvania Power & Light Co., Allentown; res., 418 Carlton Ave., Bethlehem, Pa.

BACON, ROY R., Inspector of Telegraphs, Canadian Pacific Railway, White River, Ontario, Canada

BAHNSON, G. FREDERICK R., Sales Engineer, William H. Taylor & Co., Allentown; res., 627 Wilbur Ave., Bethlehem, Pa.

BARENDS, RAYMOND E., Construction Engineering Draftsman, General Electric Co., Schenectady; res., 405 Delaware Ave., Albany, N. Y.

BARTLETT, EDWIN N., President, The Edwin Bartlett Co., North Oxford, Mass.

BATCHELER, FRED H., Asst. Professor of Electrical Engineering, University of Wisconsin, Extension Bldg., Madison, Wis.

BECK, JOHN J., General Foreman of Maintenance, Connecticut Light & Power Co.; res., 357 Grand View Ave., Waterbury, Conn.

BECKER, JAMES H., Asst. Instructor, Electrical Engineering Laboratory, Mass. Institute of Technology, Cambridge; res., 6 Elm St., Brookline, Mass.

BERTRAM, GEORGE M., Sales Manager, Lincoln Electric Co. of Canada, Ltd.; res., 46 Montclair Ave., Toronto, Ont., Can.

BLACK, DONALD C., Station Supt., Utah Power & Light Co., Hyrum, Utah.

BLACK, HOWARD M., Electrical Draftsman, Hydro-Electric Power Commission of Ontario; res., 252 Eglinton Ave., East, Toronto Ont., Can.

BLACKMAR, RAY C., Meter Man, Portland Railway, Light & Power Co.; res., 4847, 65th St., S. E., Portland, Ore.

BLAISDELL, GUY M., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston; res., 11 Merlin St., Dorchester, Mass.

BOND, FRANK B., Manager, Canada State Corporation, St. Anselme Station, Dorchester Co. P. Q., Can.

BOOTH, GEORGE G., Circuit Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

BORSHNECK, C. FRANK, Pittsburgh Representative, Habirshaw Electric Cable Co.; res., 410 Zara St., Mt. Oliver Branch, Pittsburgh, Pa.

BRIDGER, LEO J., Salesman, Westinghouse Elec. & Mfg. Co., 1062 Gas & Electric Bldg., Denver Colo.

BROWN, DARWIN S., Asst. Supt. of Production Union Gas & Electric Co.; res., 228 Piedmont Ave., Cincinnati, Ohio.

BRYANT, E. P., Chief Operator, Power House No. 2, Bureau of Power & Light, City of Los Angeles, Saugus, Calif.

BURKE, FRANCIS X., Salesman, Inter-City Radio Co., 217 Broadway; res., 52 West 48th St., New York, N. Y.

BURKE, JOHN J., Field Engineer, New England Tel. & Tel. Co., Boston; res., 116 Vernal St., Everett, Mass.

BURR, HENRY B., Asst. Plant Engineer, Wisconsin Telephone Co., 418 Broadway; res., 88 Farwell Ave., Milwaukee, Wis.

BURTT, ROBERT B., Asst. Mechanical Engineer, Transformer Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

CAMPBELL, ARCHIBALD A. I., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

CANFIELD, LAVERGNE D., District Service Manager, Westinghouse Elec. & Mfg. Co., 467 10th Ave., New York, N. Y.

CARMICHAEL, D. ALLISTER, Draftsman, Hydro-Electric Power Commission of Ontario; res., 226 Wychwood Ave., Toronto, Ont. Canada.

CARR, JAMES A., Telephone Engineer, American Tel. & Tel. Co.; 195 Broadway, New York, N. Y.

CARROLL, FRANKLIN O., 1st Lieut., U. S. Air Service, U. S. Army; res., 29 Queensberry St., Boston, Mass.

CARTER, WILLIAM L., Standardizing Laboratory, Canadian General Electric Co.; res., 15 Lisborn St., Peterboro, Ont., Canada.

CASALE, ANTHONY J., Inventor; res., Takoma Park, Washington, D. C.

CATON, JOHN J., Sales Manager, J. F. Craters Sons, Easton, Pa.; res., 321 Mercer St., Phillipsburg, N. J.

CHASE, LELAND H., Asst. Development Engineer, Holmes Electric Protective Co., 139 Centre St., New York; 179 6th Ave., Brooklyn, N. Y.

CHRISTIE, DONALD R., Instructor in charge of Dept. of Electric Construction, Harrisburg Mechanical School, 2217 Derry St., Harrisburg, Pa.

CLAYTON, HENRY C., Telephone Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston; res., 1292 Washington St., Canton, Mass.

CLYMER, HAROLD B., Journeyman Electrician for A. J. Bennett; res., 1407 Hamilton Ave., Trenton, N. J.

*COCKRILL, STERLING B., Student Engineer, Westinghouse Elec. & Mfg. Co., 1120 Ross Ave., Wilkinsburg, Pa.

COLE, IRA E., Electrical Engineer, Western Electric Co., 463 West St.; res., 622 W. 114th St., New York, N. Y.

CONNORS, LEONARD M., Switchboard Engineer, Canadian General Electric Co., Peterboro, Ont., Canada.

COTTAKIS, TASSOS M., M-V. Train Controller Co., 53 Crane St., Newark, N. J.; res., 2136 Lafontaine Ave., New York, N. Y.

COTTON, ROBERT S., Power Supt., Canadian General Electric Co., Ltd., Peterboro, Ont., Canada.

COX, GEORGE H., Electrical Engineer & Supt. of Power, National Supply Co.; res., 4113 Commonwealth Ave., W., Toledo, Ohio.

CRAMBLET, PAUL K., Vice-President & General Manager, Absolute Con-Tac-Tor Co., 127 N. Dearborn St., Chicago; res., 815 Wisconsin Ave., Oak Park, Ill.

CRANDALL, EARL D., Plant Electrician, Ottawa Station, City of Lansing, Lansing, Mich.

CRESSWELL, WILLIAM A., Field Engineer, New England Tel. & Tel. Co., Boston; res., 19 Gladstone St., Squantum, Mass.

CROWDER, CHARLES F., Vice-President, H. N. Crowder, Jr., Co.; res., 1830 Turner St., Allentown, Pa.

CUSHING, SAMUEL T., Division Plant Engineer, New England Tel. & Tel. Co., 220 Devonshire St., Boston; res., 75 Newport St., Arlington, Mass.

DAVIS, SIDNEY E., Chief Electrician, Philadelphia Q. M. Terminal, Army Supply Base, Greenwich Point; res., 1724 Berks St., Philadelphia, Pa.

DAVIS, WALDO F., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

DAY, ROBERT C., System Load Dispatcher, Utah Power & Light Co., Terminal Substation, Salt Lake City, Utah.

DEALEY, JAMES, Electrician & Maintainence Man, Crescent Pure Milk Co.; res., 554 Toronto St., Winnipeg, Man.

DE LANTY, BENJAMIN F., Supt., Overhead Lines, City Light Dept., City Hall; res., 395 E. Montana St., Pasadena, Cal.

DENIKE, ROBERT E., President, Robert E. Denike, Inc., 155 E. 33rd St., New York, N. Y.

DERR, EDGAR M., Supt. of Meters, Pennsylvania Utilities Co., 2nd & Ferry Sts., Easton, Pa.

DESAI, B. C., Student Engineer, General Electric Co.; res., Hotel Dorff, Dock St., Schenectady, N. Y.

DEWITT, EDWARD H., Engineer, Western Electric Co., West & Bethune Sts., New York, N. Y.

DIEHL, EDWARD M., Supt. of Construction, Macan Jr. Co., Glendon, Easton, Pa.

DILTS, CHESTER W., Central Office Equipment Engineer, Wisconsin Telephone Co.; res., 2821 Dunbar Place, Milwaukee, Wis.

DONAHUE, JOHN H., Electrical Foreman, Dwight P. Robinson Co., New York, N. Y.; res., 53 Coral St., Haverhill, Mass.

DOVJIKOV, ALEXANDER, Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

DUETSCHER, HARRY O., Wireman, Union Electric Light & Power Co.; res., 2516 Montgomery St., St. Louis, Mo.

DUNCAN, A. S., Construction Manager, H. N. Crowder, Jr., Co., 446 Union St., Allentown, Pa.

EILERTSEN, HENRY R., Service Engineer, Cutler-Hammer Mfg. Co., 50 Church St., New York, N. Y.; res., 17 Division St., Stamford, Conn.

ELPHICK, CYRIL M. V., Education Dept., The Metropolitan Vickers Electrical Co., Ltd., Manchester, England.

EMERSON, ROGER F., Electrical Engineer, Power & Mining Engineering Dept., General Electric Co.; res., 1716 Union St., Schenectady, N. Y.

EMERTON, HARRY E., Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston; res., Islington, Mass.

EMICH, HARRIS C., Electrical Engineer, The M. A. Long Co., Baltimore; res., 5001 Beaufort Ave., Arlington, Baltimore, Md.

EULENBERGER, CHARLES E., Testing Dept., General Electric Co.; res., 104 Glenwood Blvd., Schenectady, N. Y.

EVEREST, ERNEST L., Combination-man, Pacific Tel. & Tel. Co.; res., 1011 Columbia St., Vancouver, Wash.

EYLER, GEORGE A., General Supt. of Operations, The Edison Electric Illuminating Co., 22 Union St., Cumberland, Md.

FARON, FRANK A., Designing Engineer, General Electric Co., Schenectady, N. Y.

FARRER, HENRY E., Asst. to Secretary, A. I. E. E., 33 W. 39th St., New York; res., 8433 Lefferts Ave., Richmond Hill, L. I., N. Y.

FEAR, S. LORNE, Asst. to Chief Draftsman, Hydro-Electric Power Commission of Ontario; res., 659 Spadina Ave., Toronto, Ont., Canada.

FILES, GLENN W., X-Ray Technician, Victor X-Ray Corp., 236 S. Robey St., Chicago, Ill.

FLANIGAN, ANDREW J., Chief Electrician, Torbensen Axle Co.; res., 621 E. 130th St., Cleveland, Ohio.

FLOETING, EDWARD R., Draftsman, Western Electric Co., 463 West St., New York; res., 934 Putnam Ave., Brooklyn, N. Y.

FLYNN, P. LEO, Vice-President, The Dashew Flynn Electric Co., 417 W. Baltimore St., Baltimore, Md.

FREER, GEORGE B., Jr., Inspector, Utica Gas & Electric Co., 222 Genesee St., Utica, N. Y.

FRITZ, EDWIN H., Ceramic Engineer, Pittsburgh High Voltage Insulator Co., Derry, Pa.

GATTER, L. STEWART, C. E., Treasurer, Kern Oil & Gas Co., Solof Bldg., Charleston, W. Va.

GERRISH, SELDON W., Operator, Utica Gas & Electric Co.; 406 Lancing St., Utica, N. Y.

GIBBONS, WILLIAM J., Salesman, International Western Electric Co., 195 Broadway, New York, N. Y.

GOOB, CHARLES F., Chief Engineer, Electrical Commission of Baltimore City, 311 Courtland St., Baltimore, Md.

GORANSON, GEORGE V., Transmission Engineer, Penn. Power & Light Co., Allentown, Pa.

GRADY, FRANK R., Appraisal Engineer, Lehigh Power Securities Corp., Hunsicker Bldg., Allentown, Pa.

GRANT, CHARLES E., Testing Dept., Canadian General Electric Co.; res., 460 Sherbrook St., Peterboro, Ont., Canada.

GREENAMYER, MERLE R., Inspector, Pennsylvania System, Office Supt., Telegraphs & Signals, Central Region, 1502 Chamber of Commerce Bldg., Pittsburgh, Pa.

HAGAN, H. DAVID, Instructor, Electrical Dept., Harrisburg Mechanical School, 2217-21 Derry St., Harrisburg, Pa.

HAGE, DAVID, The United Electric Light & Power Co., 510-514 W. 147th St., New York; 483 98th St., Woodhaven, N. Y.

HAGEN, HENRY G., Equipment Asst., General Plant Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston; res., 9 Granite St., Malden, Mass.

HAGERMAN, GEORGE F., Sub-License Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

HALE, FREDERICK B., Sales Engineer, Telephone Sales Co., Long Island City; res., 627 Putnam Ave., Brooklyn, N. Y.

HALE, HOWARD O., Sales Engineer, Century Electric Co., 1827 Pine St., St. Louis, Mo.

HALL, GEORGE H., Division Plant Engineer, New England Tel. & Tel. Co., 245 State St., Boston, Mass.

HALL, WESLEY B., Instructor in Electrical Engineering, Yale University; Dunham Laboratory, Sheffield Scientific School, New Haven, Conn.

HAMILTON, ROBERT E., Electrical Draftsman, Hydro-Electric Power Commission; res., 840 Danforth Ave., Toronto, Ont., Canada.

HANLEY, EDWARD L., Engineer of Buildings, Wisconsin Telephone Co., 418 Broadway; res., 510 Murray Ave., Milwaukee, Wis.

HARVEY, HAROLD F., Secretary & Treasurer, Harvey Light & Power Co., Eldon, Mo.

HASTINGS, NORMAN H., Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

HAWLEY, CURTIS B., General Manager, Inter-Mountain Electric Co., 36-69 E. 4th So. St., Salt Lake City, Utah.

HELD, EDWARD F., Switchboard-Printerman, Southern New England Telephone Co., 188 Fairfield Ave., Bridgeport, Conn.

HENDERSON, GEORGE, Electrical Drafting, Hydro-Electric Power Commission; res., 33 Grosvenor St., Toronto, Ont.

HENDRIE, ROBERT A., Telephone Engineer, Missouri, Kansas & Texas Railway, Denison, Texas.

HERSH, GEORGE W., Electrical Testing Dept., Erie Works, General Electric Co., Erie; res., 866 Newton Ave., Lawrence Park, Erie, Pa.

HOFFMAN, W. HOLLIS, Radio Laboratorian, Bureau of Engineering, Navy Dept.; res., 1322 Kearney St., N. E., Washington, D. C.

HOTZE, JOHN W., Electrical Engineer, Western Electric Co., Inc., Hawthorne Station; res., 3337 Wilson Ave., Chicago, Ill.

HOWARD, ELMER F., Load Dispatcher, Central Illinois Public Service Co., Public Square, Marion, Ill.

HOWARD, O. T., Georgia Railway & Power Co., Gas & Electric Bldg., Atlanta, Ga.

HOWES, JOHN C., Jr., Asst. Engineer, Transformer Dept., General Electric Co., Lynn; res., 18 Cedar St., W. Lynn, Mass.

HUNT, EDWARD J., Managing Owner, Edward J. Hunt Mfg. Co., 207 Market St., Newark, N. J.

IIDA, ATSUSHI, Chief Engineer, Keihan Electric Railway Co., Temmabashi, Osaka, Japan.

IPSEN, CARL L., Designing Engineer, Industrial Heating Dept., General Electric Co.; res., 11 Lakewood Ave., Schenectady, N. Y.

IRICK, LEWIS W., Chief Electrician, Gallup American Coal Co., Gibson, New Mexico

JACOBY, S. CLIFFORD, Chief Power Station Electrician, Pawtucket Division, Blackstone Valley Gas & Electric Co., Pawtucket, R. I.

JARVIS, HAROLD L., Asst. Traffic Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

JENKS, CLIFFORD W., Chief Electrician, McMyler-Interstate Co., Bedford, Ohio.

JOHNSTON, GEORGE F., In charge of Designing Electrical Tools, Allis-Chalmers Mfg. Co., W. Allis; res., 296 25th St., Milwaukee, Wis.

JONES, ALDEN C., Manager, Clarion Div., Northern Iowa Gas & Electric Co., Clarion, Iowa.

JONES, CLYDE E., Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

JONES, JOHN L., Asst. Transmission Engineer, Southwestern Bell Telephone Co.; res., 1260A Isadore St., St. Louis, Mo.

JONSSON, S., Director of Electrical Installations, Reykjavik, Iceland.

KAAS, HANS P., New York Edison Co.; res., 149 W. 126th St., New York, N. Y.

KAESEMEYER, CHARLES F., General Foreman, Construction Dept., Pennsylvania Power & Light Co.; res., 220 N. St. George St., Allentown, Pa.

KENNARD, ROLLIN, Electrical Supt., Anaconda Copper Mining Co., Great Falls, Mont.

KINGSBURY, WILLIAM S., Maintenance Man, Big Four R. R.; res., 213 Fountain Place, Bellefontaine, Ohio.

KLINE, E. D. G., Supt. of Power Plant, Lehigh Valley Transit Co; res., 228 N. Jefferson St., Allentown, Pa.

KNOBLOCK, WILLIAM, President, Storage Battery & Appliance Corp., 929 Chestnut St., Philadelphia, Pa.

KRUEGER, HARRY H., Load Dispatcher, Utah Power & Light Co., Salt Lake City, Utah.

KRUSE, HARRY G., Machineman, New York Telephone Co., 30 Gold St.; res., 2601 Jerome Ave., New York, N. Y.

KRUSY, GODY, Experimental Engineer, Worthington Pump Works, Harrison; res., 16 Elizabeth Ave., Newark, N. J.

KURTZ, JULIUS, Chief Electrician, International Smelting Co., Tooele, Utah.

LA BARR, MYRON C., Draftsman, Electrical Div., Board of Education, Municipal Bldg., New York, N. Y.

LANE, ELIJAH R., Operator, Substations, Commonwealth Edison Co.; res., 7311 S. May St., Chicago, Ill.

LAW EDGAR D., Tester, Westinghouse Elec. & Mfg. Co., 509 Hay St., Wilkinsburg, Pa.

LAWS, FRED, Engineering & Estimating Dept., Montgomery, Ward & Co., Portland, Ore.; res., 32nd and K Sts., Vancouver, Wash.

LENDMAN, ALFRED N., Asst. Supt., Electrical Dist., Wisconsin Gas & Electric Co., Kenosha, Wis.

LEONARD, JAMES G., Testman, General Electric Co.; res., 8 Union St., Schenectady, N. Y.

LINDHOLM, OSSIAN, Station Supt., Tucuman Light & Power Co., Ltd., Maipu 129, Oficina No. 17, Tucuman, Argentine, S. A.

*LLOYD, WILLIAM J., Equipment Dept., Western Union Telegraph Co., Denver, Colo.

MANDEL, AARON, Sales Engineer, Century Electric Co., 1827 Pine St., St. Louis, Mo.

MANGOLD, ALFRED O., Electrical Draftsman, Southern Pacific Co., Beaverton; res., 1058 E. 10th St. North, Portland, Ore.

MARION, JOHN F., Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St.; res., 24 Ivy St., Boston, Mass.

MARISTANY, GABRIEL, Chief Electrical Engineer, Pesant Co., Havana, Cuba.

MARSHALL, ARTHUR W., Chief Electrician, Nayler Engineering & Manufacturing Co.; res., 514 N. 7th St., Allentown, Pa.

MARYUAMA, JUNKICHI, Chief Engineer, Kagoshima Electric Railway Co., Kagoshima, Japan; Mitsui & Co., 65 Broadway, New York, N. Y.

MAVROGENIS, ARISTOTE, Commercial Representative, Etablissements Valette & Montaret, 5 rue Deville, Toulouse, France; res., 615 Grand Ave., Milwaukee, Wis.

McCROSSEN, JAMES F., Power Salesman, Pennsylvania Power & Light Co.; res., 1250 Walnut St., Allentown, Pa.

McDANIEL, FORREST V., Head Draftsman, B. & M. Dept., Western-Electric Co., 463 West St.; res., 305 W. 150th St., New York, N. Y.

McLELLAN, HERBERT S., Telephone Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston; res., 12 Abbot St., Dorchester, Mass.

MEINS, PAUL R., Asst. Chief Operator, The Milwaukee Electric Railway & Light Co.; res., 869 38th St., Milwaukee, Wis.

MELICK, MARTIN L., Field Engineer, South Section, New England Tel. & Tel. Co., Boston; res., 91 Waldeck St., Dorchester, Mass.

NAYLOR, W. K., Electrical Engineer, Engineering Laboratory, M. & P. Div., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

NELSON, CRESCENT F., Telegraph Engineer, Radio Corporation of America, 233 Broadway, New York, N. Y.

NEWMAN, THOMAS J., President & General Manager, The Electric Motor & Engineering Co., Canton, Ohio.

NORTH, WALTER E., Electrical Engineer, Copley Cement Mfg. Co., Copley; res., 118 S. 13th St., Allentown, Pa.

NOTT, HARRY E., Supt. of Equipment, United Telephone Co.; res., 420 N. Van Buren St., Monroe, Wis.

OATEN, HERBERT C., Assistant Engineer, Turnbull &, Jones, Ltd., Auckland, N. Z.

OCHIAI, KANEYUKI, Electrical Engineer, South Manchurian Railway Co., 111 Broadway, New York, N. Y.

OLSEN, EDWARD A., Supt. of Operation, Alexandria County Lighting Co., 524 King St., Alexandria, Va.

O'MOORE, PATRICK, Electrical Engineer, West Penn Power Co., Pittsburgh; res., 321 Lehigh Ave., E. Liberty, Pa.

OYAMA, MAYSUJIRO, Asst. Professor, Electrical Dept., College of Engineering, Imperial University of Tokyo, Hongo-Ku, Tokyo, Japan.

PACKER, FRANK W., Asst. Transmission Engineer, Penn Water & Power Co., Allentown, Pa.

PAQUE, E. J., General Works, Engineer, The Pollek Steel Co., Cincinnati, Ohio.

PARKS, RALPH S., Telephone Engineer, General Engineering Dept., New England Tel. & Tel. Co., Boston; res., 58 Walnut, Watertown 72, Mass.

PEASE, EUGENE I., Junior Engineer, U. S. Engineer Dept., Fort Worden, Wash.

PEREZ, JOSE L., Electrical Designer, Ebro Irrigation & Power Co.; res., Muntaner 401-Pral., Barcelona, Spain.

PERKINS, ELLIOTT R., Telephone Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston; res., 33 Addison St., Arlington, Mass.

PERRIN, JAMES A., Realtor, Perrin & Perrin, Liberty & Pershing Sts., Cumberland, Md.

PERRY, DONALD B., Engineer, Dev. & Research Depts., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

PETERSON, GEORGE H., Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

PETERSON, JULIUS O., Power Engineering, The Pacific Tel. & Tel. Co., 620 Sheldon Bldg., San Francisco, Cal.

PFEIL, WALTER W., Engineering Dept., Public Service Electric Co., Newark; res., 81 Orange Ave., Irvington, N. J.

POWERS, PHILIP H., Asst. District Manager, Kentucky & West Virginia Power Co., Inc., Logan, W. Va.

PRICE, MYRL B., Storage Batteryman, Portland Railway, Light & Power Co.; res., 310 E. 47th St. So., Portland, Ore.

PRINCE, ALBERT, Testing Course, Canadian General Electric Co.; res., 90 rue Lock, Peterboro, Ont.

QUIRIN, GEORGE E., Electrical Asst., Dept. Natural Resources, Canadian Pacific Railway Co., Calgary; res., Strathmore, Alta., Can.

RALSTON, BYRON B., Lieutenant-Commander, U. S. N., Navy Department, Washington, D. C.; 214 Riverside Drive, New York, N. Y.

RANGER, ALFRED H., Chief Electrician, Bethlehem Shipbuilding Corp., Ltd.; res., 704 Madison Ave., Elizabeth, N. J.

RATTA, JAMES A., Telephone Engineer, General Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

RAU, EARL S., Assistant to H. O. Duerr, City Hall, Albuquerque, New Mexico.

RAUH, GEORGE J., Supervising Engineer, New England Tel. & Tel. Co., 245 State St., Boston, Mass.

REYNOLDS, JOHN P., JR., Mechanical Engineer, Pa. Power & Light Co.; res., 236 S. 13th St., Allentown, Pa.

RICHARDS, ARKLAY S., Engineer, Transmission Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

RICK, KARL L., Engineer, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

ROADHOUSE, WILBUR, Telephone Engineer, Plant Dept., American Tel. & Tel. Co.; res., 4742 Kenmore Ave., Chicago, Ill.

ROBINSON, ROBERT McT., Electrical Engineer, Nachod Signal Co., 4777 Louisville Ave., Louisville, Ky.

ROGERS, WORTH, Tel. & Tel. Engineer, Missouri Pacific R. R. Co., 1130 Railway Exchange Bldg., St. Louis, Mo.

ROSE, HUGH, Canadian General Electric Co.; res., 300 Pearl Ave., Peterboro, Ont., Canada.

ROSE, WINN M., Supt., Electrical Plant, Consolidated Gas Company of New Jersey; res., 15 Myrtle Ave., Long Branch, N. J.

ROSENBERG, LEO H., Publicity Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 7715 Brashear St., Wilkinsburg, Pa.

ROYCE, CHARLES F., Research Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 14 McKee Way, Wilkinsburg, Pa.

RUFF, JULIUS J., Asst. to Chief Electrician, Power Dept., Atlantic Refining Co., Philadelphia; res., 1037 Willow St., Norristown, Pa.

RUSSELL, EDWARD B., Switchboard Operator, Kansas City Railways Co.; res., 1324 Prospect Ave., Kansas City, Mo.

RUSSELL, STANLEY A. S., Electric Power Layout, Francisco Sugar Co., 112 Wall St., New York; res., 95 3rd Place, Brooklyn, N.Y.

RUSSIN, WILLIAM, Tester of Electrical Apparatus, Westinghouse Elec. & Mfg. Co., Pittsburgh; res., 602 Mulberry St., Wilkinsburg, Pa.

RYAN, FREDERICK C., Radio Engineer, with Signal Officer, 6th Corps Area, Ft. Sheridan, Ill.

SCHACT, CARL, Electrical Constructor, City Light Dept., Seattle, Wash.

SCHRADE, WILLIAM A., Foreman of Repair Shop, Texas Power & Light Company, Waco, Texas.

SCHRADER, HARRY W., Instructor, Buffalo State Normal School, Buffalo; res., 710 Park Ave., Dunkirk, N. Y.

SCHWARZ, ARNOLD E., Co-Partner, Electrical Contracting, The Electric Shop, Amboy, Minn.

SETO, SHOJI, Asst. Professor in Electrical Engineering, College of Engineering, Tokyo Imperial University, Tokyo, Japan.

SEXTON, H. CLAY, Engineer, American Tel. & Tel. Co., 823 Boatmen's Bank Bldg., St. Louis, Mo.

SHAW, MERRILLE C., Electric Service Supplies Co., Philadelphia, Pa.; res., 1914 Park Drive, Wilmington, Del.

SHAW, RALPH K., Telephone Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

SHERER, CLAYTON M., Asst. in Testing Dept., Penn. Water & Power Co., Holtwood, Pa.

SHOEMAKER, HERMAN, Division Foreman, Public Service Electric Co., Newark; res., 145 Franklin Ave., W. Orange, N. J.

SHORE, WILLIAM J., Electrical Engineer & Contractor, 10 W. 23rd St., New York, N. Y.

SLOAN, THOMAS S., Supt., Substations, Central Georgia Power Co., Macon, Ga.

SMITH, DONALD C., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

SMITH, JOHN R., Electrical Tester, General Electric Co., 256 S. Common St., Lynn, Mass.

SMITH, WALTER A., Designer & Draftsman, Electrical Engineering Dept., Consumers Power Co., Jackson, Mich.

SMITH, WESLEY R., Draughtsman, Pa. Power & Light Co., Allentown Pa.

SNOW, PERCY E., Electrician, Panama Canal, Ancon, C. Z.

SNYDER, THEODORE M., Electrical Engineer, Switchboard Dept., General Electric Co.; res., 1594 Union St., Schenectady, N. Y.

SORENSEN, AUGUST G., Chief Operator, Detroit Copper & Brass Rolling Mills; res., 1466 McKinstry Ave., Detroit, Mich.

SPERRY, CHARLES S., Professor of Engineering Mathematics, University of Colorado; res., 1605 Hillside Road, Boulder, Colo.

SPROUL, S. M., JR., Meter Dept., Pennsylvania Utilities Co., Bangor, Pa.

STEPHENS, EARL W., Asst. Chief Lineman, Tel. & Tel. Depts., Pennsylvania System, (Central Region), 1502 Chamber of Commerce Bldg., Pittsburgh, Pa.

STEPHENS, HENRY R., Salesman, Independent Electric Machinery Co.; res., 311 S. Monroe, Kansas City, Mo.

STEWART, WILLIAM A., Toll Wire Chief, The Pacific Tel. & Tel. Co., 901 Telephone Bldg., Portland, Pre.

STRATHY, RALPH L. A., Student Apprentice, Canadian General Electric Co., Peterboro, Ont., Canada.

SULLIVAN, GEORGE R., Master Mechanic, Kennecott Copper Corp., Latouche, Alaska.

TARBELL, RAYMOND P., District Sales Manager, Cleveland Territory, The Lincoln Electric Co., Cleveland, Ohio.

TARR, FORREST E., Division Plant Supt., New England Tel. & Tel. Co., 220 Devonshire St., Boston, Mass.

TATEBE, TEIJI, Engineer, Kawakita Electric Co., 19, Shinsakanacho Kyobashi-ku, Tokyo, Japan

TAYLOR, WALTER D. K., Equipment Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston; res., Norfolk, Mass.

THOMPSON, CLARENCE V., Electrician, Electric Storage Battery Co.; res., 3820 N. 15th St., Philadelphia, Pa.

TITUS, OLCOTT W., Salesman, Standard Underground Cable Company of Canada, Hamilton, Ont., Canada

TRIPP, JOHN P., Designer & Estimator, Dominion Bridge Co., Montreal; res., 758 St. Joseph St., Dixie Lachine, P. Q., Canada.

TROMBETTA, PANFILO, General Engineering Laboratory, General Electric Co.; res., 1241 Albany St., Schenectady, N. Y.

TURNER, MERTON H., Engineer & Switchboard Operator, Big Four Power Plant; res., 633 S. Main St., Bellefontaine, Ohio.

TWYFORD, G. T., Electrical Engineer, Hagerstown & Frederick Railway Co., Hagerstown, Md.

URE, ALBERT R., Meter Tester, Utah Power & Light Co., Bingham, Utah.

VISCHER, ALFRED, JR., Telephone Engineer, Western Electric Co., 463 West St., New York; res., 39 Childs Ave., Floral Park, N. Y.

VORONZOFF, PAUL I., Engineering Dept., New York Edison Co., 130 E. 15th St.; res., 179 W. 76th St., New York, N. Y.

WALD, DAVID, President & General Manager, Wald Electric Mfg. Corp., 248 N. 10th St., Brooklyn, N. Y.

WALTMAN, CHARLES B., Maintenance Man, Pennsylvania R. R., West Breakwater Power Plant; res., 1236 E. 83rd St., Cleveland, Ohio.

WEBB, JOHN B., Asst. Manager, Accessories Dept., Standard Underground Cable Co., 500 Westinghouse Bldg., Pittsburgh, Pa.

WEBSTER, DWIGHT S., Electrician, Atlas Crucible Steel Co., Dunkirk; res., Fredonia, N. Y.

WEIL, MABEL, Physicist in Charge, Radium Laboratory, Dr. Issac Levin, 119 W. 71st St. New York; res., 1362 Pacific St., Brooklyn, N. Y.

WELSMAN, THEODORE S., Draftsman, Hydro-Electric Power Commission of Ontario; res., 12 Walmer Road, Toronto, Ont., Canada.

WESTERVELT, ALBERT F., District Foreman, Rutherford Public Service Electric Corp. of N. J.; res., 203 Main St., East Rutherford, N. J.

WHARTON, GEORGE E., Manager, Apparatus Dept., Commercial Electrical Supply Co.; res., 4064 Mofflitt Ave., St. Louis, Mo.

WHEELER, ROY A., Outside Plant Engineer, Wisconsin Telephone Co.; res., 1468 Farwell Ave., Milwaukee, Wis.

WHITE, KENNETH C., Asst. Chief Lineman, Tel. & Tel. Depts., Pennsylvania System, (Central Region), 1502 Chamber of Commerce Bldg., Pittsburgh, Pa.

WIDMAN, JOHN G., Chief Electrician, American Lead Pencil Co.; res., 523 Park Ave., Hoboken, N. J.

WILLIAMS, RICHARD E., Draftsman, Commonwealth Edison Co., 72 W. Adams St.; res., 822 Lorel Ave., Chicago, Ill.

WILSON, MARION E., Service Engineer, Switchboard Division, Westinghouse Elec. & Mfg. Co., Atlanta, Ga.

WINTER, WILLIAM A., X-Ray Engineer, The Kny-Scheerer Corporation of America, 56-58 W. 23rd St., New York, N. Y.

*WINTHER, PETER C., Jr., Instructor, School of Engineering of Milwaukee; res., 174 Martin St., Milwaukee, Wis.

WOOD, BYRON M., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston; res., 52 Oak St., Stoneham, Mass.

WOOLEY, FRANK E., Electrician, In charge of Stator & Field Winding, Hunter Fan & Motor Co.; res., 163 W. 2nd St., Fulton, N. Y.

WOOLEY, WILLIAM C., Design Engineer, Transformer Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1340 Walnut St., Pittsburgh, Pa.

WURTS, ALDIS H., Attorney, M. B. & H. H. Johnson, 1009 American Trust Bldg., Cleveland; res., 1442 Clarence Ave., Lakewood, Ohio.

WYGANT, WALTER H., Chief Electrician Seamless Rubber Co.; res., 81 1st St. New Haven, Conn.

WYLD, CHARLES N., Draughtsman, Western Electric Co., 463 West St., New York, N. Y.; res., 604 Bloomfield St., Hoboken, N. J.

*YAMADA, HIDEO, Electrical Engineer, Engineering Dept., Tokiwa Co., Ltd.; res., 2 Nagasumi-Cho, Asakusaku, Tokyo, Japan.

YANAGIWARA, SAIJIRO, Electrical Engineer, Kyushu Hydro-Electric Co., Oita City, Kyushu, Japan.

ZBOYOSKY, WILLIAM J., Power Sales Dept., Penn. Power & Light Co.; res., 136 S. Madison St., Allentown, Pa.

ZIEGLER, TOBIAS F., Teaching Electrical Work, Rock Springs High School, Rock Springs, Wyoming.

ZUBICK, JOHN W., Research Dept., Cutler-Hammer Mfg. Co., Milwaukee, Wis.

Total 285.

*Former enrolled students.

ASSOCIATES REELECTED JUNE 23, 1921

DAVIS, MAYNARD R., Dist. Service Manager, Westinghouse Elec. & Mfg. Co., 573 W. 2nd South, Salt Lake City, Utah.

LYMAN, VAN ALLEN, Electrical Engineer, Coast Rock & Gravel Co., San Francisco; res., Aromas, San Benito Co., Calif.

O'LEARY, JOHN JOSEPH, 21 Lincoln House, Basil St., S. W. 3, London, England.

PHELPS, HOWARD S., Technical Asst., Engineering Dept., Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.

PRESTON, CHARLES R., Utility Engineer, Phoenix Utility Co., Allentown, Pa.

RICHMOND, CARL A., Lawyer, American Telephone & Telegraph Co., 195 Broadway, New York, N. Y.

TERVEN, LEWIS A., Electrical Engineer, Switchboard Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

WELD, HAROLD K., Sales Engineer, Standard Underground Cable Company of Chicago, 1548 Conway Bldg., Chicago, Ill.

MEMBERS ELECTED JUNE 23, 1921

ELMEN, GUSTAF W., Research Engineer, Western Electric Co., 463 West St., New York, N. Y.

ENGEL, NATHAN L., Supt. of Distribution Dept., Montreal Public Service Corp., 263 St. James St., Montreal, Que., Canada.

MYERS, RALPH E., Chief Engineer, Westinghouse Lamp Co., Bloomfield, N. J.

TAYLOR, THOMAS S., Research Physicist (Engineer), Westinghouse Elec. & Mfg. Co., Westinghouse Research Bldg., E. Pittsburgh, Pa.

TRACEY, ALBERT I., Chief Electrician & Asst. Manager, Cable Works, Johnson & Phillips, Ltd., Victoria Road, Charlton, London, S. E. 7, England.

WALMSLEY, HAROLD M., Engineer, The Post-Glover Electric Co., Cincinnati, Ohio.

WHEELER, EDMUND B., Electrical Engineer, Western Electric Co., 463 West St., New York, N. Y.

WHITE, WILLIAM M., Manager & Chief Engineer, Allis-Chalmers Mfg. Co.; res., 747 Summit Ave., Milwaukee, Wis.

WILSON, GOLDER P., Switchboard Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 209 South Ave., Wilkinsburg, Pa.

TRANSFERRED TO GRADE OF FELLOW JUNE 23, 1921

BURKETT, CHARLES W., Chief Engineer, Pacific Telephone & Telegraph Co., San Francisco, Cal.

CHUBB, LEWIS W., Manager, Radio Engineering Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

CONRAD, NICHOLAS J., Secretary-Treasurer & Manager, Schweitzer & Conrad, Inc., Chicago, Ill.

DAVIES, CHARLES E., General Traffic Superintendent, Canadian National Telegraphs, Toronto, Ont.

MORELAND, EDWARD L., Partner & Manager, Jackson & Moreland, Boston, Mass.

NEWBURY, FRANK D., Manager, Power Engineering Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

REED, HARRISON P., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

SMITH, ERNEST F., Superintendent of Substations, Commonwealth Edison Co., Chicago, Ill.

THORNTON, FRANK, Jr., Manager, Electric Heating Engineering Dept., Westinghouse Elec. & Mfg. Co., Mansfield, O.

WALLER, ALFRED E., Chief Engineer, Ward Leonard Electric Co., Mount Vernon, N. Y.

WEICHSEL, HANS, Chief Designing Engineer, Wagner Electric Co., St. Louis, Mo.

YOKURA, MORINOSUKE, Engineer-Captain, Chief of Electrical Engineering Bureau, Imperial Japanese Navy, Tokyo, Japan.

TRANSFERRED TO GRADE OF MEMBER JUNE 23, 1921

ANDERSON, E. R., Electrical Engineer, Supply Dept., General Electric Co., Schenectady, N. Y.

ATKINS, CHARLES G., Consulting Engineer, Chicago, Ill.

BELLINGER, W. F., Asst. Supt. Operation, Tests & Repairs, Atlanta Railway & Power Co., Atlanta, Ga.

BINGHAM, ALBERT R., Superintendent, Canadian Light & Power Co., Montreal, Que.

BRUBAKER, HENRY S., Construction Engineer, West Penn Power Co., Pittsburgh, Pa.

CASE, RALPH E., Works Manager, John Johnson Co., Brooklyn, N. Y.

CELLAR, GEORGE A., General Supt. of Telegraph, Pennsylvania System, Philadelphia, Pa.

CLEGG, T. HERBERT, Assistant to Otto M. Rau, Philadelphia, Pa.

DANIELS, RAYMOND S., Electrical Engineer, Washington Water Power Co., Spokane, Wash.

DAVIS, ERNEST W., Asst. Electrical Engineer, Simplex Wire & Cable Co., Cambridge, Mass.

FIELD, FRANK E., Electrical Engineer, Western Electric Co., New York, N. Y.

FLEMING, DAVID B., Asst. Electrical Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

FURUICHI, TATSUWO, Engineer Lieutenant-Commander, Imperial Japanese Navy, Tokyo, Japan.

GEE, PAUL M., Foreman, Electric Drafting Division, Brooklyn Edison Co., Brooklyn, N. Y.

GERHARDT, CARL L., Electrical Engineer, United Verde Copper Co., Clarkdale, Ariz.

GOLDBERG, MAXIMILIAN M., Inventor, National Cash Register Co., Dayton, O.

GRIMSLEY, A. H., General Manager, Virginia Western Power Co., Clifton Forge, Va.

HALL, MARTIN S., Superintendent, Electrical Dept., Mathieson Alkali Works, Saltville, Va.

HARBAUGH, WILLIAM M., Engineer, Lehigh Portland Cement Co., Allentown, Pa.

HARTSHORNE, WILLIAM B., Service Engineer, Public Service Electric Co., Newark, N. J.

HERSHEY, HARRY E., Telephone Engineer, Automatic Electric Co., Chicago, Ill.

HILL, ARTHUR ST. J., Associate Professor of

JAMES, HAMILTON D., Manager, Industrial Division, Westinghouse Elec. & Mfg. Co., Cincinnati, O.

JEFFERY, J. J., Asst. Electrical Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

KIDDER, HARRY A., Supt. of Motive Power, Interborough Rapid Transit Co., New York, N. Y.

KLAUDER, LOUIS T., Consulting Engineer, Philadelphia, Pa.

KNIGHT, ROBERT, Estimating Engineer, Canadian General Electric Co., Toronto, Ont.

Electrical Engineering, University of Maine, Orono, Me.

LEFEVER, ORLAND L., General Supt., Northwestern Electric Co., Portland, Ore.

LOBECK, ADOLPH J., Asst. Supt., Bronx District, N. Y. Edison Co., New York, N. Y.

McAFEE, W. KEITH, Foreman, Sunnyside Engine House, Pennsylvania Railroad, New York, N. Y.

MILBURN, WILLIAM R., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

NEBLETT, HERSCHEL W., Asst. Electrical Engineer, Steel & Tube Co. of America, Chicago, Ill.

NICHOLSON, CHARLES M., Supt., Electrical Dept., Allis-Chalmers Mfg. Co., Milwaukee, Wis.

PALMER, HARRY R., Vice-President & General Manager, Harrisburg Light & Power Co., Harrisburg, Pa.

REDING, HENRY W., Head of Electrical Dept., Atlanta Office, Lockwood, Greene & Co., Atlanta, Ga.

RICKWOOD, HAROLD A., Works Manager, Pirelli General Cable Works Ltd., Western Shore, Southampton, England.

ROMANOVSKY, CHARLES, Commercial Engineer, General Electric Co., Schenectady, N. Y.

SCHIEFER, HENRY J., Jr., President & Treasurer, Schiefer Electric Co. Inc., Rochester, N. Y.

SCHWARTING, HARRY F., Assistant to Chief Electrical Engineer, American Car & Foundry Co., St. Louis, Mo.

SKINNER, MERRILL E., Electrical Designing Engineer, Transformer Engineering Dept., Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

SNIFFIN, EDWARD H., Manager, Power Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

STEVENSON, FRANCIS L., Chief Electrical Engineer, International Harvester Co., Chicago, Ill.

THOMPSON, ROSS E., Manager, Deming Ice & Electric Co., Deming, N. M.

VANDERPOEL, WILLIAM K., General Supt. of Distribution, Public Service Electric Co., Newark, N. J.

WILLMANN, WILLIAM F., Electrical Engineer, Edison Electric Illuminating Co., Boston, Mass.

WOODRESS, JAMES L., Sales Manager, Century Electric Co., St. Louis, Mo.

WYATT, FRANCIS D., Electrical Engineer, Union Gas & Electric Co., Cincinnati, O.

YOUNG, H. W., President, Delta-Star Electric Co., Chicago, Ill.

RECOMMENDED FOR TRANSFER

The Board of Examiners at its meetings held May 13, June 10 and 16, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the secretary.

To Grade of Fellow

BAILEY, BENJAMIN F., Professor of Electrical Engineering, University of Michigan, Ann Arbor, Mich.

FORTESCUE, CHARLES L., Electrical Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

HERZ, ALFRED, Engineer of Electrical Tests, Public Service Co. of Northern Illinois, Chicago, Ill.

LAWSON, CHARLES S., Section Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

WYMAN, FRANK T., President, Packard Electric Co., Ltd., St. Catherines, Ont.

To Grade of Member

BAER, FREDERICK L., Contract Sales Engineer, Automatic Electric Co., Chicago, Ill.

BEATTYS, WILLIAM H., JR., Representative, Westinghouse Traction Brake Co., Chicago, Ill.

COLE, JAMES L., Asst. Superintendent, Westinghouse Elec. & Mfg. Co., Newark, N. J.

CROFT, TERRELL, Directing Engineer, Terrell Croft Engineering Co., St. Louis, Mo.

GUILDFORD, CHARLES T., General Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

LAWSON, JOEL S., Sales Engineer, R. Thomas & Sons Co., New York, N. Y.

LEWIS, DONALD M., Secretary & Treasurer, General Manager & Chief Engineer, Livingston-Niagara Power Co., Avon, N. Y.

MARTIN, WILLIAM H., Dept. of Development and Research, American Telephone & Telegraph Co., New York, N. Y.

OSBORNE, CHARLES P., Supt. of Light & Power, Portland Railway Light & Power Co., Portland, Ore.

ROBBINS, ARTHUR H., Supt. of Distribution, Electric Light & Power Co. of Abingdon & Rockland, North Abingdon, Mass.

RUSSELL, HERBERT A., Designing Engineer, Toronto Hydro-Electric System, Toronto, Ont.

TERVEN, LEWIS A., Electrical Engineer, Switchboard Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

THAU, WALTER E., Engineer, Marine Section, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

WAGNER, EFFINGHAM B., Electrical Engineer, Lehigh Valley Coal Co., Wilkes-Barre, Pa.

WELLS, JAMES H., Chief Electrical Draftsman, Brooklyn Edison Co., Brooklyn, N. Y.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before July 31, 1921.

Ainsworth, Chester D., (Member), Boston, Mass.
Alexander, James P., (Member), New Haven, Conn.
Anderson, Idof, Worcester, Mass.
Angus, Roy F., New York, N. Y.
Attwood, Stephen S., Ann Arbor, Mich.
Beyersdorfer, Fred A., Brooklyn, N. Y.
Bucklin, A. H., Burley, Iowa.
Careless, George M., Philadelphia, Pa.
Carlson, Edwin L., San Francisco, Cal.
Chapleau, Dean D., Schenectady, N. Y.
Chatley, Charles C., Boston, Mass.
Cox, Harold J., New Haven, Conn.
Curtis, Edward C., Wichita, Kans.
Daley, Carl F., Arlington, Mass.
Dee, F. Kyrl, New York, N. Y.
De Remer, James S., Denver, Colo.
Dunmire, Russell P., (Member), Irwin, Pa.
Duste, Arthur W., Denver, Colo.
Earle, Ralph P., Philadelphia, Pa.
Elieson, Edwin E., Murray, Utah.
Fahning, Otto R., New York, N. Y.
Gillis, Melvin D., Erie, Pa.
Gordon, Bert E., Ogden, Utah.
Graner, George S., Hazleton, Pa.
Harris, Frank St. C., Deep Rock, Nova Scotia.
Hemingway, Harry A., Lynn, Mass.
Hennefer, Arthur McA., Salt Lake City, Utah.
Inouye, Noboru, Baltimore, Md.
Johnson, Chesley H., Philadelphia, Pa.
Jones, Frederic P., Grand Falls, Maine.
Kaelber, J. George, Rochester, N. Y.
Killebrew, Emmet S., (Member), Albany, Ga.
Kissel, Walter P., Ogden, Utah.
Knott, Charles E., San Francisco, Cal.
Kuhns, John H., Cleveland, Ohio.
Kulka, Eugene R., Brooklyn, N. Y.
Langford, Wilbur H., Preston, Idaho.
Latorre, Robert J., Schenectady, N. Y.
Liunge, Paul, New York, N. Y.
Lundberg, Fred L., Salt Lake City, Utah.
Marasigan, Vivente, Manila, P. I.
Marion, Frederick R., New York, N. Y.
Marti, Othmar K., Milwaukee, Wis.
Morton, Thomas Q., Prairie View, Texas.
Mueller, Edwin, St. Louis, Mo.
North, John R., Sawtelle, Cal.
McCormick, Rollin D., Hawthorne, Ill.
Pelton, Willis H., Erie, Pa.
Pratt, Chester C., Salt Lake City, Utah.
Randall, Ernest G., Montour Falls, N. Y.
Rees, Edward H., (Member), Alton, Ill.
Reynolds, Lewis C., (Member), Geneva, N. Y.
Richards, Otho C., St. Louis, Mo.
Riggs, Oliver S., New York, N. Y.
Rose, Otto K., Detroit, Mich.
Rosenberg, Abraham, New York, N. Y.
Schamberger, Sanford O., Schenectady, N. Y.
Schiemer, Edward W., New York, N. Y.
Shanck, Roy B., New York, N. Y.
Smith, Leon E., (Member), W. Lynn, Mass.
Steck, M. M., Salt Lake City, Utah.
Stephens, William T., Milwaukee, Wis.
Taggart, Willard T., Philadelphia, Pa.
Taylor, Clarence M., Cleveland, Ohio.
Thompson, Earl L., Lancaster, N. Y.
Tomlinson, Carroll M., Pittsburgh, Pa.
Twyman, Neal, Boulder, Colo.
Van Norman, James W., James Island, B. C.
Veatch, James S., Mansfield, Ohio.
Wagner, George, New York, N. Y.
Waterman, John H., Boston, Mass.
Whitall, Charles W., Pawling, N. Y.
Wichman, Ralph D., San Francisco, Cal.
Wilch, Nole H., Beaver Dam, Ohio.
Williams, Jerome H., New York, N. Y.
Yates, Raymond F., New York, N. Y.
Total 76.

Foreign

Ashmore, Joseph, Manchester, Eng.
Baba, Kumeo, Tohokudaigaku, Sendai, Japan.
Butterworth, Alfred, (Member), Cawnpore, India
Freuchen, Thord H., Rancagua, Chile.
Krogh, Gunnar E., Kristiania, Norway.
Kuroyanagi, Kenichi, Oimachi, Tokyo, Japan.

Morishima, Teiichi, Sukegawa, Japan.
Niethammer, Friedrich, Prag 1, Bohemia.

Electric Propulsion of Ships

BY W. E. THAU
General Engineer, Westinghouse Elec. & Mfg. Co.

THIS paper will deal primarily with the electric propulsion of large ships, and as illustrative of large ship drives, a description and some discussion will be given of the propelling machinery of the *U. S. S. Tennessee*. In order, however, to make certain general comparisons helpful to the discussion, it will be necessary to introduce to some extent all feasible types of propelling equipment.

It is believed to be generally recognized by those who have made a broad study of the situation that the type of drive best suited to a given ship depends upon the characteristics of the ship, its trade route, and the cargo to be carried. These factors are so diversified that no unqualified preference can be held for any one type of propulsion, or in other words, there is a proper field for all principal types of ship drives.

The following types and arrangement of power drives have been applied with more or less success:

1. Direct-connected reciprocating engine.
2. Direct-connected turbine.
3. Geared turbine.
4. Turbine electric with direct-connected motor.
5. Turbine electric with geared motor.
6. *Internal combustion engine, direct-connected.
7. *Internal combustion engine, geared.
8. *Internal combustion engine- or Diesel-electric using direct-connected motors.

The principal objections to the reciprocating engine are those incident to its poor economy, and to some extent its weight and space factors. This type of drive, however, will exist for some time to come, as it has obtained a high state of development, and is at the present time better understood by the operating engineers. It is felt, however, that this condition will be greatly overcome as soon as the engineers now under training have become acquainted with the newer types of drive.

The development of the direct-connected turbine has probably gone as far as can be expected. This type of drive is being discarded because of its poor performance, as both the propeller and the turbine are operated at speeds not adapted to the best operating conditions of either.

There have been numerous applications of the geared turbine drive, and although there have been some disappointments, the general results indicate that the geared turbine drive has come to stay and enjoy a field of its own.

The turbine electric drive using direct-connected motors is a perfectly logical and applicable type of propulsion. Owing to the economy of high-speed turbines, alternating current is found best suited as a-c. turbo-generators lend themselves very readily to high-speed operation. Two types of motors have been proposed and used, namely the induction type and the synchronous type. The synchronous motor drive has slight weight and cost advantages over the ordinary induction motor drive, for the reason that the unity power factor of the synchronous motor permits a smaller generator, and the synchronous motor is cheaper to build than the induction motor. On the other hand, the induction motor drive has maneuvering advantages as it requires less skill in handling and possesses much better starting torque characteristics. The economy of the two types should be about the same.

Turbine electric drive using geared motors will probably see very little more development as the speed reduction can be accomplished efficiently with direct connected motors without gears.

The internal combustion engine, direct-connected to the propeller shaft, has been applied with considerable success in European countries, and is being given considerable serious attention at the present time in this country. From the fuel consumption standpoint, the direct-connected Diesel drive is far superior to any type of steam drive, and is certain to enter an era of prosperity. When compared with Diesel electric drive, however, the fuel economy advantages of the direct Diesel drive are small and other factors enter which show a gain for the Diesel electric over the direct-connected Diesel. At least, there is little choice from the fuel cost standpoint, as the additional weight of the direct-connected Diesel over the Diesel electric drive causes the net returns to be practically

*Diesel engines or the equivalent.

Presented at a Joint Meeting of the N. Y. Section of the American Institute of Electrical Engineers and the Metropolitan Section of the American Society of Mechanical Engineers, New York, N. Y., January 28, 1921.

the same. As a matter of fact, the additional cargo that can be carried by a Diesel electric ship shows to a considerable advantage over short trips. The net fuel consumptions of the two drives are brought still closer for the reason that the direct-connected electric motor can be easily arranged for a lower and more efficient propeller speed than is usually the case with the direct-connected engine. There is a tendency to speed the direct-connected engines up in order to decrease weight per shaft horse power, resulting in lower propeller efficiencies.

The ordinary internal combustion engine using gears will probably see very little more development under present conditions.

The internal combustion engine or Diesel electric drive using direct-connected motors offers possibilities superior to those of any other type of drive, as will be shown in detail later.

For convenience, ship drives may be classified as follows, according to capacity of the propelling equipment: (1) Ships up to and including 6000 h. p.; and (2) Ships in excess of 6000 h. p.

For drives up to and including 6000 h. p., we might logically have reciprocating engine, geared turbine, turbine electric, direct-connected Diesel, and Diesel electric types of propulsion.

For drives in excess of 6000 h. p. we might have geared turbines and turbine electric. At the present writing, it is believed that the development of the Diesel engine in direct-connected units in excess of 3000 h. p. is not perfected. Neither has the development of the high-speed Diesel units for electric drive been perfected in sizes which will permit a drive in excess of approximately 6000 h. p.

Unquestionably, the prime consideration is reliability, while economy, simplicity, cost weight and space are important but secondary considerations. One must not be unmindful of the fact that when a ship leaves port, it must absolutely rely on its propelling equipment to reach its destination, and therefore, the lives of crew and passengers as well as the safe transport of the ship and its cargo are dependent upon the satisfactory performance of the propelling machinery. For this reason, reliability should not be sacrificed for any other consideration. Reliability necessitates close adherence to rugged and thoroughly proved apparatus which must, of necessity, stand more or less abuse without danger of failure. The machinery must operate continuously for days and possibly for months without shutting down, and must be simple within reason and thoroughly understood by the operators. Economy, cost, weight space, etc., are important in that they determine the relative earning capacity of the ship.

Merchant Shifs

With these general statements in mind, let us consider more closely the merits of electric drive, first for merchant ships, and second for battleships. As stated above, there are two general systems of electric propulsion, namely that in which the prime mover is the steam turbine and that in which the prime mover is the Diesel engine. With the turbine electric drive, the electrical equipment is of the a-c. type for the reason that a-c. turbo-generators are inherently better suited for the high economical speeds of turbines. With the Diesel electric drive, the electrical equipment is of the d-c. type, because of its flexibility, ease of speed control and simple requirements of the engine governors. If alternating current were used with Diesel electric drive, the engine governors would have to be highly refined as it would be necessary to operate the generators in parallel; whereas with direct current, the generators may be operated in series, thus permitting relatively simple engine governors. Even with parallel operation of the d-c. generators, the governor problem offers no serious difficulty, however, there are other decided advantages in favor of the series operation which will be discussed later. In the case of the turbine electric drive, the propeller speed is varied by throttling the turbine, and reversal of propellers is effected by reversing the motors connections. In the case of the Diesel electric drives, the propeller speed is varied any amount from zero to a maximum in either direction, without opening a single circuit, by merely adjusting the generator voltage by means of a simple field rheostat, the engines always operating at constant speed.

In the turbine electric drive, the motors are direct-connected to the propellers. As most ships up to 6000 h. p. are of the single-screw type, there is usually but one turbo generator and one motor. The electrical characteristics are usually 50 to 60 cycles, 1100 to 2200 volts, and polyphase. The control of the apparatus is effected from a central control station usually located in the engine room. The switches and turbine control valves are controlled by means of simple levers, symmetrically arranged and suitably interlocked in order to prevent improper operation. All necessary gages and electrical instruments are mounted upon a panel directly in front of the operator, so that the performance of the machinery is under his observation at all times.

The turbine is equipped with a speed governor, over-speed stop governor and throttle valve. Where the throttle valve is not used to regulate the speed, some form of "power limit stop" is necessary to prevent excessive overloads being imposed on the machinery when maneuvering or by other causes

In the case of twin-screw ships having two generating units, turbine electric drive possesses the advantage of flexibility over direct-connected and geared drives, in that the failure of either generating unit will not seriously cripple the propelling equipment. Should one unit fail, the remaining unit would deliver equal power to both propellers to the extent of its full equivalent capacity, thus enabling the ship to make about 70 to 75 per cent of full speed. This is also true to a large extent in the case of the geared turbine drive using cross compound turbines, as the failure of a high

or low-pressure turbine element would mean the loss of only from 40 to 50 per cent of the power. In the case, however, of complete expansion turbines, the failure of one unit would necessitate dragging that screw, resulting in a serious retarding effect. Large ships invariably have twin, tripple or four screws, and therefore, the flexibility of the electric drive is an important advantage.

For ships up to 6000 h. p., (the larger sizes having twin screws) the Diesel electric type of propulsion possesses marked advantages over all other types. With this type of drive, any reasonable number of generating units may be used, independent of the arrangement of the propellers. It is, therefore, possible to use a number of relatively small reliable, high-speed Diesel engines driving direct-connected d-c. generators[1]. By using a number of the small units, the disadvantages of large Diesel engines are obviated. Aside from the reliability thus obtained, there is the added important advantage of flexibility with regard to reserve power, and as will be shown later, this advantage is possessed in an extreme degree only by the Diesel electric drive.

The electrical apparatus is well understood, thoroughly tried out, and there is consequently no question as to its reliability. The motors are separately excited at constant potential in one direction while the generators are supplied with excitation through a reversing field rheostat so that any desired voltage may be obtained from zero to the maximum in either direction. With this arrangement, the speed of the motors is directly proportional to the voltage of the generators. Therefore, the control is as simple as could possibly be desired.

Series connection of the generators with the motors interposed to reduce the ground voltage to a minimum has certain advantages over parallel connection of generators. For the purpose of discussion, let us assume a single-screw drive consisting of six generators and a motor consisting of two separate units mounted on the same shaft. Electrically, the machines would be arranged in series as follows: Three generators, one motor unit, three generators, one motor unit. On the basis of 250-volt generators, the maximum ground voltage would be 750 volts, although from the standpoint of current, the system has all the advantages of a 1500-volt circuit. This arrangement of generators and motors is independent of the number of either. Even with an uneven number of generators in series, the motor may be on different screws as in the case of a twin-screw drive, and still permit independent control of the port and starboard screws. However, with the same or opposite rotation of the screws, the amount of speed difference obtainable is somewhat limited, although wholly within requirements. In this case, the speed difference between the propellers is obtained by adjusting the motor fields. An even number of generators is preferable with twin-screw ships, however, as it affords more flexible and more positive control.

The advantages of the series system over the parallel system from an engine operating standpoint has already been covered.

With the series arrangement, more power can be obtained from remaining generator units in case of failure of one or more generator units, without providing excess capacity in the motors. The reason for this is that each of the remaining generators can be operated at normal voltage and the field of the motors weakened to increase the propeller speed to a value which will load the remaining generator units to their full capacity. With parallel operation, it would be necessary to lower the voltage of each generator a certain amount, thereby operating them at reduced capacity; or else to operate the remaining generators at full voltage and provide additional field capacity in the motors so that the speed could be lowered the required amount by increasing the motor field. Thus, in case of failure of a generator unit, parallel operation would either afford slightly less power than series operation or would necessitate slightly larger and heavier motors.

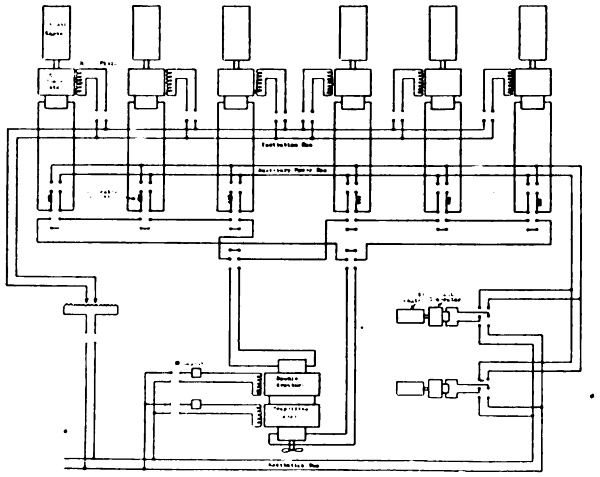

Fig. 1—Diesel Electric Drive, Schematic Arrangement Electrical Connections

The Diesel electric system of ship propulsion possesses a flexibility of reserve power in the case of failure of prime movers which far surpasses any other type of drive. For example, assume a case in which there are three generators and one motor. Should one of the engines fail, the remaining two units could be operated at full capacity, giving two-thirds the total voltage and the motor speed increased by weakening its field to a point where the propeller would require two-thirds of full power, with a resulting ship speed of approximately 88 per cent. In the case of two engines failing, the available speed of the ship would be ap-

1. It is not the intent of this paper to discuss Diesel engines, and it is assumed that it is generally recognized that Diesel engines having relatively small cylinders and operating at reasonably high speeds are thoroughly reliable and simple.

proximately 70 per cent of full speed. And to assume the remote case of all main engines failing, the ship could make steerage way on the auxiliary generating sets.

The multiplicity of units of the Diesel electric system affords another advantage of great importance, namely, that units can be overhauled at sea without entailing any serious loss of speed.

In the way of a summary, the following table of comparison of the various principal drives will be of interest. In arriving at the figures given, all items of machinery and supplies necessary to the main propelling machinery were considered; foundations, water, fuel, etc., were taken into account. However, it was necessary in some cases to make certain assumptions, but an effort was made to place such assumptions on the conservative side, so as not to show an exaggerated comparison. Further, certain major figures are at great variance in practise, and the table is, therefore, given as indicative of the trend of this comparison rather than actual proportions. The figures for turbine electric drive and geared turbine drive are based on the same steam conditions.

The figures are based on a 3000 h. p. ship operating over a 4000 mile course at a speed of 11 knots, and making a total of 14 single trips per year. The geared turbine ship is taken as unity. Owing to the present unsettled conditions, it is hardly possible to make an intelligent cost comparison.

Drive	Fuel Consumption	Machinery Weight
Geared turbine	1	1
Turbine electric	1.06	1.05 to 1.10
Direct-connected Diesel	0.49	1.10 to 1.25
Diesel electric[2]	0.57	0.75

Battleships

The requirements of propelling machinery for battleships differ from those for merchant ships, principally in the degree of reliability and maneuvering ability. The reliability factor is of considerably greater importance, and must be made secondary to no other consideration. The maneuvering ability of a battleship is of great importance because of the range of speed at which it operates, and the promptness and accuracy with which it must respond to signals. Certain refinements are necessary for battleships which are not advisable for merchant ships, but because of the continually changing personnel of the former, these should always be kept within reasonable simplicity.

It is not the intent of this paper to compare various types of drives for battleships, and therefore only a few brief remarks will be made in this connection. The advantages of electric drive for battleships, or warships, lie particularly in the flexibility of the arrangement of the machinery with respect to its protection from torpedo attack. Secondary advantages lie in the availability of full backing power and flexibility of control. Flexibility of control is important, both from the standpoint of normal operation, and also emergency operation, as in case of a failure of one of the main prime movers. Within reason, the machinery can be placed where it is best protected from torpedo attack. The total floor area occupied by the propelling machinery and its weight might be slightly in excess of a well designed geared turbine drive. However, if the geared turbine drive is arranged to be equally well protected from attack, it is possible that the slight advantages of these two factors would be of very minor consideration. Unfortunately, there are no comparable geared turbine drives in operation, or under construction, to enable a close comparison of these factors to be made. Similarly, there are no directly comparable ships having geared turbine propelling machinery to enable a comparison to be made of the economy. (In this connection, sister ships of the *New Mexico* having direct-connected main turbines and geared cruising turbines have shown decidedly poorer economy under all conditions than the *New Mexico*).

It is safe to say, however, that the difference in economy, if any, would be very little. The geared turbine drive might show a slightly better economy at full power, whereas the electric would be expected to show better economy at the lower powers and cruising speeds, providing equal efforts are made toward economy by design and operation. In the case of the geared drive, it would be necessary to use all turbines (except where cruising turbines are provided) for any speed, whereas with the electric drive only a sufficient number of generators are operated to supply the power required for a given speed. This enables the generating equipments of the electric drive to be operated at full power nearly all the time. Furthermore, since the motors have two sets of windings, or the equivalent, the generators and turbines can be operated at higher average speeds over the entire range, resulting in better economy.

There can be no question as to the reliability of electrical apparatus as the propulsive power for ships of this class. Electrical machinery has been developed over a long period of years and has proven extremely reliable in all sizes, and the experience with this class of apparatus will support the statement that it is as reliable as any other class of machinery that can be installed on ships.

The experience of the engineer officers who have had charge of an electrically driven battleship, and also of battleships having other types of machinery is that the electrically driven ship is more easily controlled, and affords quicker response to signals than any other of type drive. The equipment can be made in such a manner that the entire propelling equipment is under

2. There is a farther decrease in fuel consumption with Diesel electric drive which has not been taken into account in this comparison, namely that due to lower propeller speeds obtainable with low-speed motors.

the control of one operator. In fact, such an arrangement will be used with the new battleships and battle cruisers. In this case, the control will be almost entirely electro-pneumatic, and the main operating board will resemble the control boards used in the large railway switch towers. Any desired rapidity of operation within reason can be otained with the electrical equipment. For instance, upon receipt of a signal to go full speed astern from full speed ahead, the propellers can be made to turn over in the reverse direction inside of a period of approximately ten seconds.

Also the facility with which electrical energy can be measured and indicated, enables the instantaneous conditions of the propulsive equipment to be observed at any time, and therefore enable the operating force to detect excessive shaft friction, damaged screws or other abnormal operation. The electrical instruments are also beneficial in operating the machinery at its maximum economy at all times.

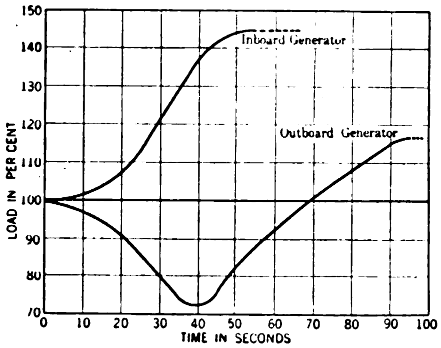

FIG. 2—TURNING WITH 35-DEG. RUDDER (POWER LIMIT NOT SET)

Starting and running requirements under normal sea conditions are not severe. If, however, precautions are not taken to limit the power, it is possible to impose large overloads on the machinery when turning a ship or reversing. The accompanying curve shows the manner in which the power of the inboard and outboard sides varies when making a turn with 35 deg. rudder. The particular curve shown has been interpolated from the curve obtained on the battleship *New Mexico* when making 19 knots and turning with 35 deg. rudder. It will be noted that the power of the generator supplying the inboard side increases rapidly during the first 50 sec., at which point it reaches the maximum output of the turbine. On the other hand, the power delivered by the generator supplying the outboard side decreases rather rapidly during the first 40 sec., and then begins to increase rapidly until a constant value is reached at about 90 sec. An analysis of the curve shows that the inboard side developed an overload of approximately 45 per cent when the maximum power of the turbine was reached. The outboard side dropped to about 75 per cent of normal load at the end of the first 40 sec., and then increased to a value corresponding to approximately 15 per cent overload at the end of 90 seconds. The total power at the end of 90 sec. corresponds to approximately 130 per cent load.

If such conditions as those mentioned above are not guarded against, it would be necessary to carry excessive excitation on the generators continuously as the equipment would have to be ready at all times to meet the requirement. This would result in considerably larger generators. However, to overcome this condition, a form of power-limit stop is provided, the function of which is to limit the amount of steam taken by the turbine to a predetermined value, which under normal operating conditions corresponds to an overload of about 10 per cent. The shape of the turning curves and the overloads obtained varies with the different ships, and it is therefore necessary to conduct a series of "drop out" tests on each ship in order to determine the field current that must be carried continuously at the different speeds to enable the ship to be maneuvered without liability of the motors and generators pulling apart.

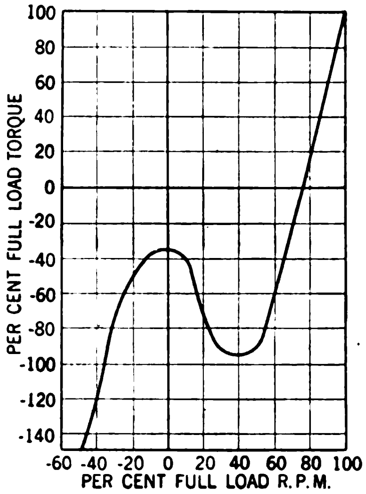

FIG. 3—PROPELLER TORQUE CHARACTERISTICS—REVERSING
Ship going ahead at constant speed.

Fig. 3 shows the conditions which exist when reversing a battleship at full speed. The relative proportions of this curve also depend upon the ship in question, but the curve shown can be considered more or less typical as showing the backing conditions. In order to show the motor torque available for taking care of the backing condition, a series of motor speed-torque curves have been plotted in Fig. 4. The motor in question is of the wound-rotor type, having adjustable external resistance. A few speed-torque curves have been drawn for different secondary resistance values, but with liquid rheostats, there would be an infinite number of such curves as the external resistance thus provided varies from a maximum to the short-circuited condition of the rotor. With this type of rheostat, it is possible to obtain the maximum torque at any instant. An inspection of the ship torque curve will

show that the speed of the propellers drops to approximately 75 per cent when the power is taken off. This portion of the curve is represented by the straight line to the right. At this point, the motor connections are reversed and the motors produce a torque opposing the turning effort produced by the motion of the ship on the propellers. This reverse motor torque then builds up to approximately full-load value at 40 per cent ahead revolutions, and then decreases to approximately 35 per cent when the propellers are brought to a standstill. When the speed of the propellers is increased from zero rev. per min. to values as low as 40 per cent full-load rev. per min. in the backing direction, the torque increases very rapidly, attaining at this point a value slightly in excess of 100 per cent which is the maximum speed that can be obtained without exceeding full-load tor-

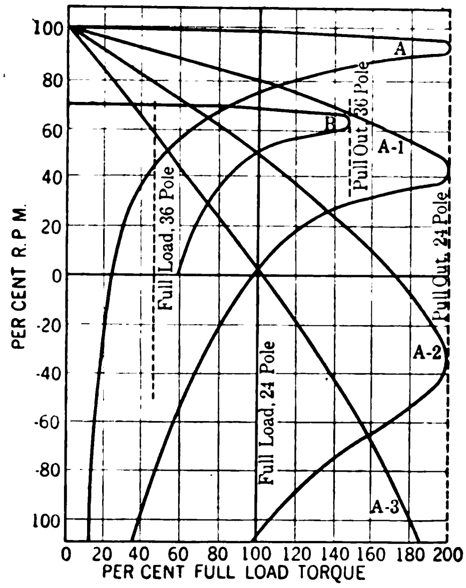

FIG. 4—U. S. S. TENNESSEE MOTOR SPEED-TORQUE CHARACTERISTICS

A—24-pole (wound secondary)
A₁, A₂, A₃.—24-pole winding with external resistance
B— 36-pole (squirrel-cage winding)

que of the motor. This curve, however, is plotted on the basis of the ship maintaining its full lineal speed through the water. Under actual conditions, however, the ship will slow down considerably in the time taken to reach this point, and it will therefore be possible to obtain a higher rotational speed of the propellers in the backing direction than this curve indicates.

The most vital part of the curve is that at about 40 per cent of full-load speed when bringing the propellers to a stop condition. In the case of wound-rotor motors, this condition presents no difficulty as it is possible to obtain torques considerably in excess of normal at any speed by simply adjusting the external resistance. In the case of squirrel-cage motors, however, it is necessary to introduce a special design so as to obtain a speed-torque curve which will enable the motor to deliver torque safely in excess of this requirement, and under the conditions of operation described.

Further details of backing and turning conditions can be obtained from articles by Commander S. M. Robinson, U. S. N. published in the *Journal* of the American Society of Naval Engineers, from which data for the above curves have been taken. All such conditions must, of course, be taken into strict account in designing the propelling equipment and it is obvious that the turbines, generators, motors, and control must be designed as a unit in order that each will have characteristics which are sufficient to enable all parts of the equipment to function properly under the required conditions.

Description of Apparatus. The propelling machinery of the *U. S. S. Tennessee* consists of four direct-connected, 2-speed motors supplied with 3-phase power through suitable control equipment at approximately 3400 volts and 34.6 cycles (full speed) by two direct-driven, 2075 rev. per min. turbo generators. The generators are excited from one of the 300-kw., d-c. auxiliary sets through a booster set, so designed as to vary the 240-volt bus voltage in either direction to a value best suited for the given condition. All engine room auxiliaries necessary to the main propulsion such as the main and auxiliary condenser circulating and condensate pumps, the lubricating and governor oil pumps, the oil cooler circulating pump, and the main motor ventilating blowers are driven by d-c. motors supplied with power from the same generator which is used for supplying the excitation. One auxiliary generator in each engine room is sufficient to supply the auxiliary load just mentioned.

From the maximum speed to a speed slightly in excess of 16 knots, two generators are used, and the motors are connected to the 24-pole winding; speeds below this are obtained with only one generator in use. Speeds up to and including 15 knots can be obtained with the motors connected to the 36-pole winding.

The steam operating conditions are 280 lb. gage at the boilers, 250 lb. gage at the turbine throttle, and a vacuum of 28.5 in. of mercury referred to 30 in. barometer.

Main Motors. The main propelling motors are of the induction type and are wound for two definite speeds at full frequency, there being a 24-pole and a 36-pole winding. The primary or stator has two independent windings, one for each set of poles. One set of slots accommodates both of these windings, there being two coil sides of each set of coils placed in the slot, one directly above the other.

The rotor has a three-phase, two-parallel star-connected winding, having balancer connections operating as such on the 24-pole winding. The 24-pole winding is connected to three slip rings. The balancer connections are connected to points of equal potential in such a manner as to form short-circuit paths for the rotor conductors when the stator is connected to the 36-pole winding, thus forming an ordinary squirrel-cage winding having straps connecting the

rotor conductors together instead of resistance rings.

In general, the design of the motors follows standard land practise. There are, however, certain features, particularly in connection with the insulation of the windings that have been given special consideration to guard against the deleterious effect of salt and moisture conditions. The insulation is of the best known material and is applied and treated in accordance with thoroughly tried methods. The coils are form wound, and completely insulated before being placed in the slots. The insulation of the straight part of the coil which is imbedded in the slot consists principally of mica with just sufficient fibrous material to serve as a binder. The mica folium and mica plate constituting this insulation are applied loosely by hand, and the coil then placed in a special machine equipped with electrically heated bars which revolve under spring pressure around the wrapper. This process softens the bond, and permits the wrapper to

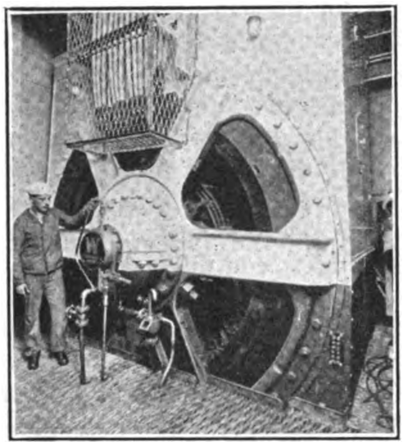

Fig. 5—Starboard Outboard Motor

slide on itself, resulting in an extremely solid and compact insulation. After the ironing process is completed, the coils are placed in cold presses and pressed to the required dimensions. The ends of the coils where flexibility is required are insulated principally with specially treated fibrous material. Whereever cotton tape or other material subject to deterioration at relatively low temperatures is used, it is for convenience of assembly only, and in no case are the insulating or mechanical qualities depended upon where there is a danger of the neighboring iron or copper reaching a temperature questionable for class A insulation. The tape constituting the insulation for the ends of the coils is given several treatments of insulating varnish during the process of winding. This tape is joined to the insulation of the straight part of the coil with specially prepared cement. The outside coverings are thoroughly filled with insulating varnish by means of several successive treatments; each coating being baked on for a long period, resulting in an insulation having a coating which is impervious to moisture and capable of withstanding salt deposits and foreign particles of dirt, etc., which may eventually find their way into the motor.

The slots are lined with tough paraffined fish paper cells in order to protect the insulation of the coil from injury during the assembling operations. This cell laps over the top coil, forming a protection of the coil from injury by the micarta wedges which are driven in the teeth of the slots. The individually formed coils are separated from each other by micarta spacers and any additional space in the slot is filled with micarta plate so that there will be no room for coil movement.

The connectors joining the coil ends are insulated with thoroughly treated fibrous tape.

The bottom layer of stator coils is securely laced to a strong insulated steel supporting ring which, in turn, is supported to the frame by means of bolted brackets. Another insulated steel ring support is placed between the two windings of the stator and held in place by means of copper wires which extend around the ring and the individual coil ends of both stator windings. With this type of construction, all coil extensions are grouped into a single mass which is rigidly supported from the motor frame, thus preventing coil distortion from any cause whatsoever.

The rotor coil extensions rest firmly upon a wide insulated support, to which they are secured by heavy insulated bands.

The mechanical construction of the motor is of the self-contained type in which the bearings are carried by suitable brackets which fit into recesses in the stator frame. The entire motor is supported by feet cast integral with the frame on either side. The bearing housings are readily adjustable radially by means of jack screws in the brackets, and after being adjusted, are bolted rigidly to the bracket.

The ventilation is supplied by duplicate d-c. motor-driven exhaust blowers, each capable of 12,500 cu. ft. per min. maximum. In addition to these separate blowers, the rotor itself is provided with fan vanes which assist in the ventilation and which will supply sufficient air to enable the motors to be operated for brief periods at full load in case of failure of the separate blowers. The separate blowers are mounted on the top of the motors, and draw the air through the motor and discharge it through suitable ducts to the deck. The system of ventilation consists of the axial flow of air through the core and end windings, the air being drawn in through openings in the brackets and discharged through a radial duct at the middle of the core to an outlet at the top of the motor.

Each motor is capable of delivering a maximum of 8375 h. p. at a speed of about 185 rev. per min.

The stator is provided with six thermocouples which are used in connection with potentiometers mounted in the control room for measuring the hot-spot temperatures of the windings. This device

gives actual measurement of the actual hot-spot temperature and readings taken therefrom need no further correction except the 5 deg. for insulation drop.

In order to maintain the temperature of the motors above that of the surrounding air when the motors are idle, d-c. heaters are provided. These heaters consist of a series of tube resistors secured to the motor frame and so arranged as not to cause any excessive local heating.

Main Generators. The main generators are designed and constructed in accordance with standard land practise, except that the rotor is of the totally enclosed type. The stator coils are insulated in substantially the same manner as described for the motor coils. Each generator is capable of delivering a maximum of about 15,000 kv-a. at approximately 36½ cycles.

The air pressure for ventilation is supplied by means of blowers secured to each end of the rotor. The air is drawn from a duct below the generator through the end bells, entering the machine at each end of the rotor. From there, it is forced through the end windings,

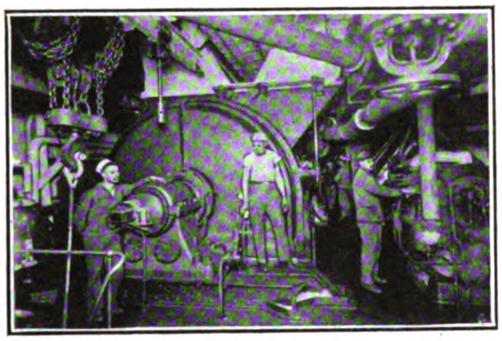

FIG. 6—MAIN TURBO GENERATOR, FORWARD ENGINE ROOM

core, and air gap axially, and discharged radially through a central opening in the core and passes from thence through a duct to the deck.

The rotor consists of a solid steel forging having radial slots for receiving the windings. The winding consists of a series of turns of bare copper strap, the insulation of which consists entirely of mica and asbestos.

Similar to the motor, the generator is provided with thermocouples for measuring the hot-spot temperatures. These thermocouples also connect to the same potentiometer board in the control room.

In order to prevent the generator from sweating when idle, steam heating coils are provided. These coils are so located as not to cause any excessive local heating and all joints and connections to the pipe are made outside of the frame of the machine so as to avoid steam leaks into the machine.

Turbines. The turbine is of the combined impulse and reaction type, allowing complete expansion of the steam in one cylinder. Steam from the throttle valve and governor valve is admitted to openings in the top and bottom at the center of the turbine through control valves in the connections to these openings, and thence into various nozzle groups. The steam expands in the nozzle and passed through a set of impulse blades and thence through single-flow, high-pressure reaction blading; having passed through this high-pressure reaction blading, the steam divides, one-half continues through the low-pressure blading on the same end of the turbine, and the other half flows through an overhead connecting pipe to the low-pressure reaction blading on the other end of the turbine. An exhaust connection is provided at each end of the turbine.

The number of hand nozzle control valves to be opened at one time depends upon the load and varies from one to three valves.

The speed, of course, is regulated by the governor valve only, the use of the hand valves being merely to obtain the best economy and to prevent overloading of the boilers at the various standard speeds.

The turbine is coupled to the generator by means of a pin-type flexible coupling.

The glands for preventing leakage along the rotor shaft are of the combined steam and water sealed type. The water gland is designed to effectively seal at all speeds from and above half speed. Below half speed, the steam seal gland is used. The steam pressure is regulated by a reducing valve in the pipe line to the glands. The water for sealing is supplied by a small connection from the feed line. The water and steam for gland sealing is controlled by special automatic gland control valves.

Briefly, the principal speed-control system consists of a governor driven directly from the turbine shaft through suitable gearing. The governor which is capable of holding a practically constant speed at any speed from about 25 per cent to the maximum, is essentially a dead weight governor in which the dead weight is replaced by a hydraulic piston, resulting in a type of governor capable of functioning over a wide range of speed by varying the hydraulic pressure on the piston. The speed is adjusted hydraulically by means of a control valve in the main control room which regulates the oil pressure. A double-seated poppet valve located on the main steam inlet to the turbine is controlled through a floating lever oil pressure relay system from the main governor, and this valve controls the amount of steam required to maintain the speed for which the system is set. The governor control valve is also operated through a suitable oil pressure relay by a separate over-speed governor secured to the end of the turbine shaft. In addition, this overspeed governor also operates the main throttle valve in case of necessity.

In order to limit the power input to the turbine on overload conditions to an amount which will prevent excessive overloads on the machinery, and also prevent priming of the boilers, a power-limit stop is provided. This power-limit stop is arranged to limit the travel of the governor linkage in the direction which

admits more steam, as mentioned above. The position of the stop is adjusted electrically from the main control room through a system of gearing operated by a small motor. In order that the operator may know the position of the power-limit stop at any instant, an electrical position indicating system is provided, the transmitter of which is driven by spur gearing from the power limit stop mechanism. The indicator is mounted on the main control board in the control room under the direct observation of the operator.

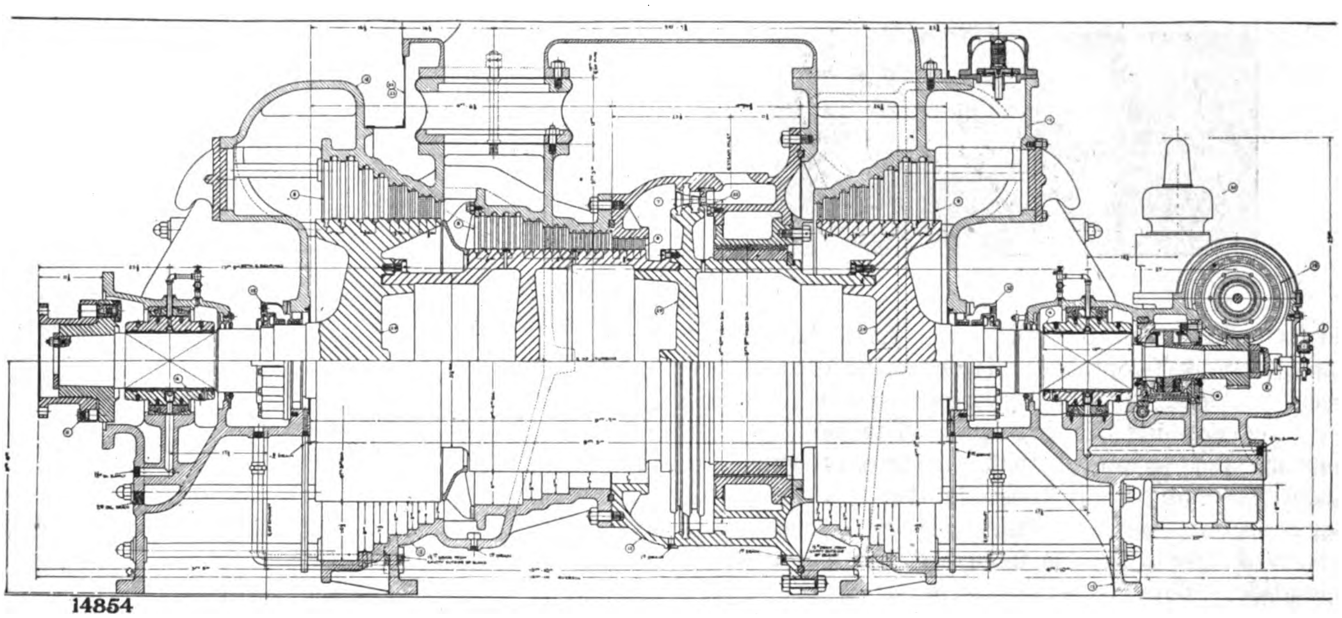
In operation, this system function as follows: The speed of the ship is set from the control room for any given standard by means of the hydraulic speed-control system. The power-limit stop is then adjusted to limit the motor speed to a few revolutions above that corresponding to the standard speed. Should an overload occur from turning or from any other cause, the speed-control governor will tend to maintain a constant speed by admitting more steam. However, as the governor linkage has only an additional limit of travel corresponding to the few revolutions increase in motor speed, the steam which can be admitted to the turbine is therefore limited, and consequently the overload has a fixed value for any given condition.

The power-limit stop may also be used for adjusting the speed of the turbine below any value for which the main speed governor system is set, and it accomplishes this in a similar manner to throttling.

Since the speed is a function of the oil pressure, oil gauges mounted in the control room give a further check on the proper functioning of the entire turbine control system.

The over-speed stop may be operated direct from the over-speed governor, hand trip in the engine room, or by wire pull from the control room.

The turbine and generator bearings are lubricated by means of forced lubrication through a system of delivery and return pipes. Oil for the governor control system is also supplied from the same system. The oil is delivered to the governor system at 80 lb. pressure and to the bearings at 5 to 10 lb. pressure through a reducing valve or other suitable means. The oil pumps for circulating this oil are of the positive displacement rotary type. Two pumps are provided in each engine room, one of which is motor driven and the other turbine driven, the turbine-driven pump standing by as a spare. Normally, the motor-driven pump is used. However, upon failure of the motor-driven pump from any cause, an arrangement of pistons operated by the oil pressure will automatically cause the turbine-driven pump to be placed in operation.



14854

FIG. 7—CROSS-SECTION TURBINE U. S. S. TENNESSEE.

Main Control. As in the case of any other drive, the control for the electric drive such as is installed on the *Tennessee* is operated under orders from the bridge. All controlling apparatus necessary for the operation of the main propelling machinery is located at a central place known as the control room, and the operating levers are arranged so that the operator faces forward. All operations for the control of the ship are effected in this control room except the actual starting of the turbines. The circuit breakers for handling the main circuits of the propelling machinery are of the oil break type, of sufficient capacity to safely open the circuits under full power and voltage conditions, although in normal operation the circuit breakers are never opened or closed while the circuits are alive, suitable interlocks being provided to guard against improper operation. All primary breakers are arranged in two rows athwart ship having an aisle

between them through which the breakers may be inspected and removed, if necessary. Secondary short-circuiting breakers and the liquid rheostats for controlling the motor secondaries are located back of the operating aisle.

The circuit breakers are designed with special reference to ease of operating, having wedge-shaped contacts of the multiple finger type. The circuit breakers are operated in pairs from single-control

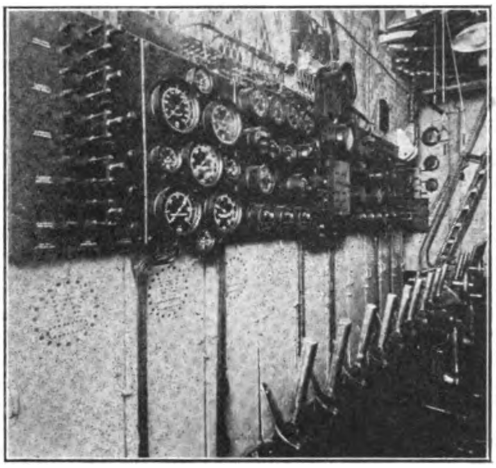


FIG. 8

levers. In order to kill any particular circuit completely, self-contained disconnecting devices have been provided on the reverser breakers, generator breakers and tie breakers. The breaker mechanism is so arranged that the breaker must be opened before it is possible to disengage the disconnecting device. This provision safe-guards against danger to the men in case of improper or faulty operation. The inspection or repair of the circuit breaker or circuits of any one or two motors at a time is thus facilitated, and can be executed while the ship is under way.

The levers for operating the circuit breakers and the liquid rheostat valves are arranged in a single row directly aft of the circuit breaker structure. All instruments and gages for indicating the performance of the machinery are located on control panels secured to the circuit breaker structure directly in front of the operators. The levers are arranged symmetrically so that those on the left of the central position operate the circuit breakers in the after generator and port motor circuits, while those on the right of the central position operate the circuit breakers which control the circuits of the forward generator and starboard motors.

The connecting rods and bell cranks between the levers and the circuit breaker mechanism are located beneath the false floor which forms the operating platform.

The pedestals on which the turbine control valves mentioned above are located, and also the levers for operating the generator field switches are located in the center of the lever group. Suitable mechanical interlocks of the crotch and rod types are provided so as to prevent improper operation of the switch levers. All interlocking is so arranged that the field must be off and the steam control reduced to a low value before any of the operating or set up breakers can be operated. This interlocking also necessitates proper sequence of operation in either starting or stopping, the broad purpose of which is to safe-guard the machinery.

The arrangement of the control is such that either side of the ship can be operated independently of the other side when two generators are in use. With the tie breakers closed and either generator in operation, the port and starboard propellers may be operated in the same or opposite directions as desired, but at the same speed.

All starting and maneuvering are done on the 24-pole winding.

When the motors are connected on the 24-pole winding, the secondaries are controlled by means of

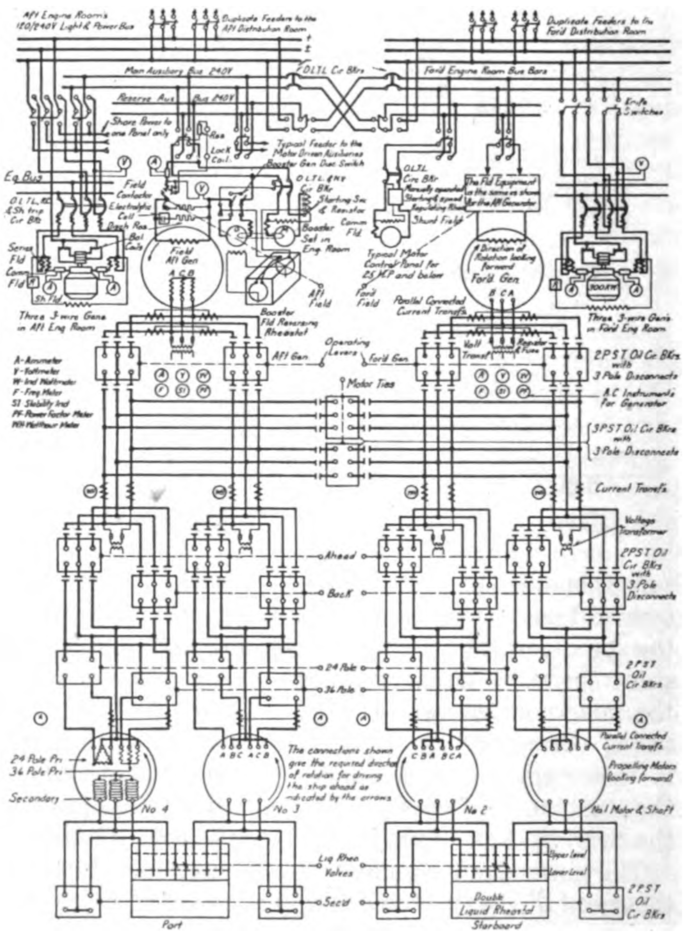

FIG. 9—DIAGRAM OF CONNECTIONS OF THE MAIN A-C. AND D-C. CIRCUITS FOR THE PROPELLING MACHINERY OF THE U. S. S. TENNESSEE

liquid rheostats. There is one double rheostat for port motors and one for starboard motors. The rheostat consists essentially of a 2-compartment tank, the lower compartment of which serves as a reservoir for the electrolyte and also as a container for the

cooling coils, while the upper compartment contains the electrodes which are of the plate type. When it is desired to use a rheostat, the valve in the upper compartment operated from the control stand by means of a lever, is closed, thus allowing the liquid to rise in the upper compartment. (The liquid is being continually circulated through the upper compartment at a low level by means of motor-driven pumps.) The rate at which the liquid rises depends upon the setting of the regulating valve located in the delivery

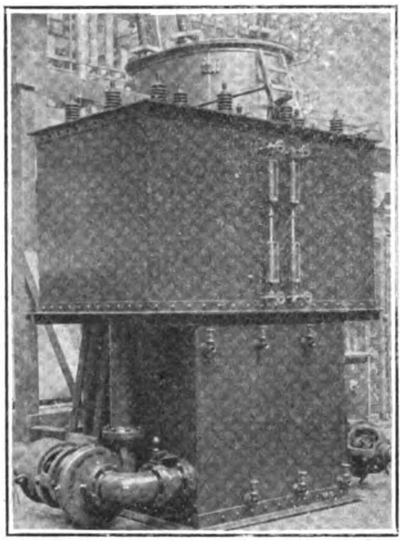

Fig. 10

pipe of the pump. This valve can be adjusted to suit the desired operating condition. After the liquid rises to its maximum level, it overflows to the bottom compartment. After the maximum level has been reached, the motor secondary is completely short-circuited by means of an oil circuit breaker which is operated by a lever from the control stand. The electrolyte consists of a solution of ordinary sodium carbonate.

In order to transmit the power from the generators to the control room circuit breakers, and from there to the motors, three-conductor lead-covered cables are used, each cable containing all three phases, there being a sufficient number of these cables in parallel to take care of the total power. The cable ends are provided with pot heads forming water-tight seals from which the respective conductors are brought out and connected to very substantial and well insulated bus structures located over the switches in the control room, and at the motors and generators in the motor rooms and engine rooms respectively.

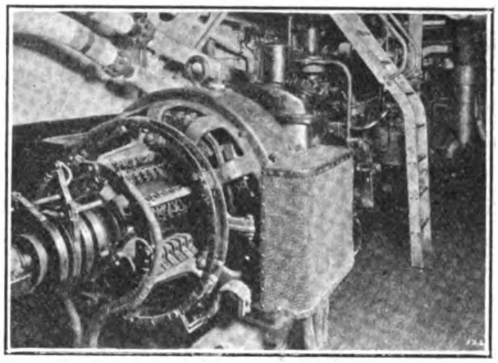

Fig. 11

The excitation for the main generators and power for the auxiliaries necessary to the propelling equipment is supplied from one of the 300-kw. sets in each engine room, as stated above. Connections of these circuits to the 300-kw. sets are made ahead of the carbon circuit breakers in order that an interruption by means of the circuit breakers will not shut power off the exciting circuits or the auxiliaries. The engine room auxiliaries and the motor ventilating blowers are provided with ordinary starting devices having individual circuit breaker protection.

STOCK OWNERSHIP IN PUBLIC UTILITIES

A new campaign for distributing its stock among the customers and employes of the Southern California Edison Company has been carried on for several months with unusually gratifying results. The advantage of consumer ownership in a public service utility has been generally recognized and the plan has met with notable success in the case of this company.

On June 24 the company completed the fifth month of its new stock-ownership campaign, at which time it had sold $7,985,000 par value of its common stock. This sets a record for the sale of utility stock to individual buyers. In 1917 when the company began offering its stock to its consumers it had a total of 1,864 stockholders. It now has 17,500 stockholders.

An interesting angle of consumer ownership is suggested by the following case: A man owning 20 acres under irrigation has a waterfall on the back of his property and it has an effective head capacity for generating 15 h. p., which would be about adequate for irrigation pumping on the average 20-acre ranch. His electric power bill, at rates fixed by the State Railroad Commission, is about $150.00 per year. If he were to undertake to harness his own cataract, it would cost him about $2,000 to install a small turbine and electric generator. The interest at 8 per cent would be $160 per year, the depreciation about 8 per cent per year, and the life of the machinery would not exceed 15 years. The purchase of twenty shares of stock would cost him $1,880, and yield him $160 per year, showing that he could get his power very much cheaper by being a partner owner in the utility than he could by developing his own waterfall.

On the Equivalence of the Two Theories of the Single Phase Induction Motor

BY V. KARAPETOFF

Professor of Electrical Engineering, Cornell University.

It is shown that the two equivalent diagrams of a single-phase induction motor, viz., the one deduced from the revolving-field theory and that from the cross-flux theory, can be converted into each other. In other words, the two theories lead to the same performance of a motor with given design constants. It is also shown that many other equivalent diagrams are possible and that one of these contains a variable impedance depending upon the slip in one parallel branch only, the other parts of the circuit being constant.

THERE are two theories of the single-phase induction motor that are in general use among engineers, *viz.*:

1. *The rotating-field theory,* according to which the single-phase motor is replaced by two polyphase motors in torque opposition, with the stator windings in series and with separate rotors. This theory leads to the equivalent diagram shown in Fig. 1.

2. *The cross-field theory,* according to which there are two separate air-gap fields, one in space phase

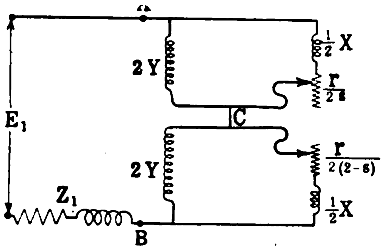

FIG. 1

and the other in space quadrature with the stator winding. This theory leads to the equivalent diagram shown in Fig. 2.

These two theories are considered in detail in E. Arnold's Wechselstromtechnik, Vol. V., Part 1, (1909) Chaps. 7 and 8, and the equivalent diagrams are proved there. Each theory leads to a circle diagram for the locus of the primary current, and on p. 15 Arnold shows that three points on the two circles coincide. From this fact he concludes with sufficient reason that the two theories lead to an identical performance for a given motor, and that if one of the two theories is correct, the other must be correct.

The process of finding the position of the center and the radius of the circle according to either theory is quite tedious, and the resulting graphical construction rather involved. On the other hand, the equivalent diagrams shown in Figs. 1 and 2 can be used analytically for the predetermination of performance or for any other investigation of the motor, without representing them graphically. It is of interest therefore to show directly the equivalence of the two diagrams of connections and to deduce a method of transforming one into the other.

In both figures, E_1 is the line voltage and Z_1 is the primary impedance consisting of the resistance of the primary winding and of its leakage reactance. Since Z_1 is taken into account in the same manner in both diagrams we are not further concerned with it in our comparison of the two diagrams. Y is the exciting admittance of the main magnetic circuit and is shown in the usual manner in Fig. 2. In Fig. 1 this admittance is shown separately as $2\,Y$ for each of the two component polyphase motors. Each fictitious component motor has only one-half as many turns as the actual motor and for this reason the exciting admittance has to be doubled (Arnold, ibid., p. 152.)

The meaning of the other symbols in the figures is as follows: $X = j\,x_2$ is the secondary leakage reactance and is used in the analytical part of this treatment as an operator in complex notation. The resistance r is that of the rotor, considering it as a single-phase circuit reduced to the primary number of turns. It is known from the general theory of the polyphase induction motor that in the equivalent electric diagram the load and the secondary resistance together are replaced by the resistance r/s, where s is the slip of the machine (see, for example, the author's "Electric Circuit," p. 123). One of the component machines in Fig. 1 runs at a slip s, the other at the slip $2-s$. Moreover, only one-half of the resistance of the actual

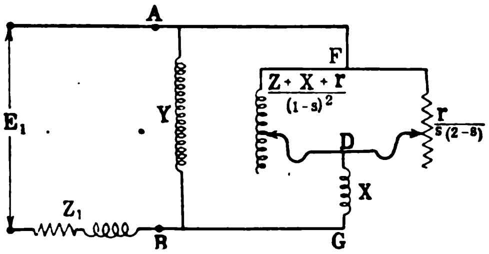

FIG. 2

single-phase machine must be assigned to each polyphase machine. This explains the meaning of the resistances $\frac{1}{2}\,\frac{r}{s}$ and $\frac{1}{2}\,\frac{r}{(2-s)}$. For the same reason $\frac{1}{2}\,X$ is assigned to each polyphase motor. The same quantities enter in Fig. 2 in a different form resulting from the crossfield theory. The impedance Z in this diagram is that of the main exciting circuit, so that $Z = \frac{1}{Y}$.

For the sake of abbreviation we shall also introduce the following notation:

$$Z' = \frac{1}{Y'} = \frac{1}{2}\,X + \frac{1}{2}\,\frac{r}{s} \tag{1}$$

$$Z'' = \frac{1}{Y''} = \frac{1}{2}\,X + \frac{1}{2}\,\frac{r}{(2-s)} \tag{2}$$

The total impedance between the points A and C in Fig. 1 is equal to $(2\,Y + Y')^{-1}$, and that between C and B is $(2\,Y + Y'')^{-1}$. Hence, the total equivalent impedance between the points A and B is

$$Z_{AB} = \frac{1}{2\,Y + Y'} + \frac{1}{2\,Y + Y''}$$

$$= \frac{4\,Y + Y' + Y''}{(2\,Y + Y')\,(2\,Y + Y'')} \qquad (3)$$

If the diagrams in Figs. 1 and 2 are equivalent, then equation (3) must also give the value of the total impedance between the points A and B in Fig. 2. To get the impedance between the points F and G, the admittance Y must be subtracted from Z_{AB}^{-1}. We then get

$$Y_{FG} = Y_{AB} - Y = Z_{AB}^{-1} - Y \qquad (4)$$

or, using the value of Z_{AB} from equation (3), we obtain, after reduction

$$Y_{FG} = \frac{Y\,Y' + Y\,Y'' + Y'\,Y''}{4\,Y + Y' + Y''} \qquad (5)$$

The corresponding impedance is

$$Z_{FG} = Y_{FG}^{-1} = \frac{4\,Y + Y' + Y''}{Y\,Y' + Y\,Y'' + Y'\,Y''} \qquad (6)$$

Multiplying the numerator and the denominator of this fraction by $Z\,Z'\,Z''$ and remembering that the Z's are the reciprocals of the corresponding Y's, we get

$$Z_{FG} = \frac{4\,Z'\,Z'' + Z\,Z'' + Z\,Z'}{Z'' + Z' + Z} \qquad (7)$$

In order to obtain the impedance between the points D and F, the reactance X has to be subtracted from the foregoing expression. We get then, after simple algebraic transformations,

$$Z_{FD} = Z_{FG} - X =$$
$$\frac{(2\,Z' - X)\,Z'' + (2\,Z'' - X)\,Z' + Z\,(Z' + Z'' - X)}{Z'' + Z' + Z} \qquad (8)$$

With the help of equations (1) and (2), this is directly reduced to

$$Z_{FD} = \frac{Z''\,r/s + Z'\,r/(2-s) + Z\,r/s\,(2-s)}{Z + X + r/s\,(2-s)}$$

$$= r\,\frac{Z + X + r}{(Z + X)\,s\,(2-s) + r} \qquad (9)$$

The total admittance between the points F and D is

$$Y_{FD} = Z_{FD}^{-1} = \frac{1}{r}\;\frac{(Z + X)\,s\,(2-s) + r}{Z + X + r} \qquad (10)$$

By adding and subtracting r in the parentheses of the first term of the numerator, this expression is transformed into

$$Y_{FD} = \frac{1}{r}\;\frac{(Z + X + r)\,s\,(2-s) + [r - r\,s\,(2-s)]}{Z + X + r}$$

or, writing the denominator separately under each term,

$$Y_{FD} = \frac{s\,(2-s)}{r} + \frac{(1-s)^2}{Z + X + r} \qquad (11)$$

Expression (11) represents two admittances in parallel and means that the circuit between F and D consists of the resistance $\dfrac{r}{s\,(2-s)}$ in parallel with the impedance $\dfrac{(Z + X + r)}{(1-s)^2}$. This conclusion agrees with the values shown in Fig. 2, which have been induced independently, from the cross-field theory. The equivalence of the two theories is thus proved.

Equation (10) is shown below to lead also to the equivalent diagram in Fig. 3. This diagram has the

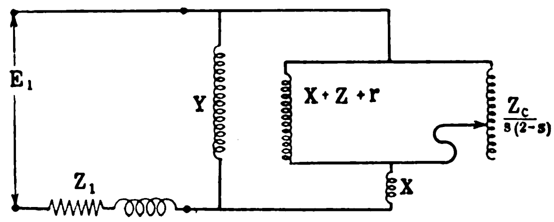

FIG. 3

advantage over Fig. 2 in that the impedance of one branch only is a function of s and varies with the load. As a matter of fact, the total admittance Y_{FD} may be resolved into two or more admittances in parallel or impedances in series in an infinite variety of ways, so that there is an infinitely great number of equivalent diagrams of the kind shown in Figs. 2 and 3. All of them are characterized by the shunted exciting admittance Y and by the series reactance X.

To prove that equation (10) leads to Fig. 3, we simply write the denominator separately under each term and thus obtain

$$Y_{FD} = \frac{(Z + X)\,s\,(2-s)}{r\,(Z + X + r)} + \frac{1}{Z + X + r} \qquad (12)$$

This shows that Y_{FD} consists of two impedances in parallel, namely $Z + X + r$, and $\dfrac{Z_c}{s\,(2-s)}$ where

$$Z_c = r\,\frac{Z + X + r}{Z + X} \qquad (13)$$

The fraction by which r is multiplied is a known complex quantity of the form $a + j\,b$, so that

$$Z_c = r\,a + j\,r\,b \qquad (14)$$

and this value is used in Fig. 3.

Neglecting the core loss, the impedance Z is a pure reactance, so that *approximately* we may put the foregoing ratio in the form

$$1 + \frac{r}{Z + X} = 1 - j\tan\phi \qquad (15)$$

where ϕ is a small known angle which is constant for a given motor and is determined by the constants r, Z, and X of the machine. Hence, approximately

$$Z_c = r - j\,r\tan\phi = \frac{r}{\cos\phi}\,\epsilon^{-j\phi} \qquad (16)$$

Two noteworthy papers on the single-phase induction motor, by Hellmund and by Lamme, as well as an extensive and stimulating discussion by others, will be found in the A. I. E. E. TRANS., Vol. 37 (1918), pp. 539-702.

SELF-CORROSION NOT STRAY CURRENT ELECTROLYSIS, SHOWN AT SELKIRK, MANITOBA

Evidence has been gradually forthcoming, from a number of independent investigators, that cast iron pipe is not the indestructible material that it was formerly supposed to be by engineers; and the recognition of the possibilities of self-corrosion by responsible engineers and chemists ought to have considerable bearing upon the numerous controversions respecting damage to water pipes, gas pipes, and lead cables, which is usually charged against stray current electrolysis from electric railways, if there is a railway near enough to receive the blame for the damage.

A perplexing feature that sometimes arises in an electrolysis situation, is the persistence of pipe corrosion, at spots well removed from the pipe joints, in areas where the pipes could not have been electrically positive to the surrounding earth. When the soil carries electrolytic salts in solution, self-corrosion is easily possible, in places where stray current electrolysis could not happen.

The facts that are now being brought to light about the possibilities of self-corrosion, coupled with the availability of recently devised methods for determining conclusively whether a pipe is positive or negative to the earth, will enable electrolysis situations to be handled in the future on a basis of proved fact instead of prejudice, fear or conjecture; and professional electrical engineers, called into electrolysis situations will do well to bear this in mind.

The following investigation of a case of chemical corrosion of iron pipe is reported by W. Nelson Smith, consulting electrical engineer of the Winnipeg Electric Railway Co.

A party of professional chemists and engineers from Winnipeg made a personal inspection of a six-inch water main, about 100 feet of which had been recently exposed in the course of excavating for the pipe tunnel between the new Selkirk hospital and the boiler house.

As the water supply system of the hospital is secured from wells drilled on the property to a depth of 250 to 300 feet, and the piping system is entirely separated from the Selkirk water supply, and as the hospital is more than half a mile from the western outskirts of the town, and not less than 1¼ miles from the northern extremity of the Selkirk trolley line, it was said to be quite outside any possible path of stray current from the electric railway. The only electric current on the property is a 60-cycle alternating current for lighting, and the United States Bureau of Standards, it was pointed out, had proved by exhaustive and long-continued experiment, that it was impossible for an electric current of this character to cause destructive electrolytic action on buried metal structures.

The pipes examined, although they had not been laid for more than eight years, were shown to be affected by some corrosion of the cast iron, well advanced in many spots, not only near the joints but in the middle of the pipe.

The progress of corrosion was observed in its various stages, and the corroded metal in the pits eaten into the pipes was similar in appearance to the products of corrosion observed on damaged water pipes in Winnipeg. All such damage, wherever it had happened in the city, it was stated, had always been attributed solely to electrolysis from stray currents leaking from the electric railway tracks.

The presence of soluble salt crystals in considerable quantity was also observed by all the party on clay freshly excavated from the new trenches in the street in front of the hospital. The similarity of this clay and its salt content, to the clay and its contained salts as met with all over Winnipeg and vicinity was remarked upon by all present.

This water pipe had thus been imbedded in earth containing salts that are known to be chemically active, and further, by reason of its location, had been entirely free from access of stray direct current, which can only dissolve the metal where it leaves a buried pipe to enter the surrounding earth. Stray-current electrolysis was, therefore, admitted to be impossible under the circumstances.

The only inference that could be drawn from the facts noticed by the party was that the observed corrosion could only have been caused by the chemical activity of the solutions of the so-called alkaline salts.

It was further pointed out that it had also been recognized for several years past, by practising civil engineers, and more recently by public authorities and the public generally, that these alkaline salts, the sulphates, chlorides, carbonates and bicarbonates of magnesium, calcium and sodium, which are widely distributed through the soil of western Canada, are very corrosive to concrete made of Portland cement, no matter how carefully the concrete is mixed and deposited.

Chemical research work started about a year ago under the direction of W. Nelson Smith, M. E., and conducted personally by Dr. J. W. Shipley in the laboratory of the University of Manitoba, has brought to light many facts respecting the behavior of commercial cast iron, lead, and copper, in contact with neutral solutions of the above so-called alkaline salts. This research is now so far advanced that a definite report on the main outstanding facts will be forthcoming during the present summer.

Voltage Regulation and Insulation for Large Power, Long Distance Transmission Systems

BY FRANK G. BAUM

Consulting Engineer, San Francisco, Cal.

Heretofore the distance to which power could be transmitted has been limited. This limitation is now removed by a simple method of loading the line with synchronous condensers, so that the current and voltage may be kept practically in phase. High power factor and hence high efficiency result, and the voltage rises of the system are very much reduced, thus reducing insulation strains.

A standard frequency of 60 cycles is advocated for the national system, and 220,000 volts is proposed as standard for extra large-power, long-distance transmission. The system of regulation proposed will result in practically constant voltage at all points of the line at all loads. And power may be taken from or supplied to the line at any point, and the power over sections of the line or over the entire line may be reversed and the constant voltage system maintained.

A simple diagram is given, and this shows that for a 60-cycle, 220,000-volt line, the line-charging current supplies about two-thirds of the capacity current required for about 0.8 load or 320 amperes load current, and that for larger loads the synchronous condensers supply leading and for smaller loads lagging current. Thus it is seen that the transmission line has largely inherently the currents required for self-regulation, if we correct initially the power factor of the loads to near unity. Every induction motor added to the power system calls for a certain capacity current for correction of power factor to reduce the losses from motor through to the power station. Every synchronous motor added, instead of an induction motor, helps in the economy all along the line, improves the service and reduces the menace resulting from large lagging currents. Every synchronous motor added becomes an asset to the entire system. Power factor correction should be done largely at load centers, the final correction and regulation being accomplished by the transmission line capacity current and the synchronous condensers.

The advantages of such a system are Simpler and cheaper generators, transformers standardized for one voltage, insulation strains reduced and a safer system results, and with constant voltage the flow of power has the greatest possible flexibility. (So far as known the proposal and method of presenting is new).

This will give a system power transmission comparable to railway transportation, with a flexibility not possible in the or·inary system which does not have the constant voltage feature.

The problems of ·he line insulation are discussed, and especial attention is called to the necessity for low air and leakage resistance stresses. The leakage resistance stresses are most important. For best results these should be distributed as uniformly as possible over the insulator surfaces, under the worst conditions. Results of a large number of tests are gi en.

A new diagram is given which results from analysis of experimental data, from which the characteristics of long strings of insulator strings may be calculated, knowing the constants of the units relatively.

The wet and dry arc-over may be controlled if desired, as shown by the illustrations, but it is believed best to strive for the elimination of arcs, except for cases of accident.

While the present insulators with some form of shielding or grading (and with a system of regulation as given in Part I) will no doubt give more satisfactory results for 220,000 volts than is now obtained on lower voltage lines, it is desirable that further work be done with a view to crystallizing the best method of handling the line insulation. There is here an opportunity for some pioneer work, which will give us all that is desired, resulting in a high factor of safety for the line insulation.

I. VOLTAGE REGULATION OF TRANSMISSION LINES

Introduction

WHEN a power man is asked how far electric power may be transmitted, he often qualifies his answer by restricting the frequency, or the per cent power loss, or by saying one mile for each 500 or 1000 volts between wires, etc., etc. The only real qualification should be that we can transmit power as far as economy dictates. That is, we are now, as herein shown, able to transmit power as a commodity from its points of production to the places of its use without restriction as to distance, etc.—*so long as it pays to transmit the power*.

Engineers are prone to pay too much attention to the losses or percentage losses in transmission. But the real answer to the transmission problem—assuming it now possible to give constant service—is the value of the product at the end of the transmission. A man may start out with a truck load of gasoline and transport it so far that only one-half, say, remains, but the remainder—not diminished in quality—may be very profitably used. In many operations only a small fraction of the energy measured in kw-hr. is used at the end of the cycle and yet the operation may be very profitable.

In the electrically driven trains, machine tools—in the incandescent lamp, etc., only a small part of the energy is finally utilized. In wireless transmission of messages only an extremely small fraction of the transmitted energy is received, and yet it is successful. (Wireless transmission of large power is not possible and wire transmission is a refinement over wireless transmission.) The electric transmission of power

Presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

may be at high efficiency, even for long lines as shown here, and give good service.

Let us suppose we have a cheap source of water power and that the losses in transmission are 10 per cent average for each 200 miles. Then the efficiency of transmission for each 200 miles—giving practically perfect service as will be shown—will be approximately as follows (conductor area remaining constant):

Section	Average Loss	Efficiency & Power
0 to 200 miles....	10 per cent	90
200 to 400 "	9 " "	81.9
400 to 600 "	8 " "	75.35
600 to 800 "	7 " "	70.08
800 to 1000 "	6 " "	65.78

For 1000-mile transmission this shows about two-thirds of the power delivered or one-third lost. The above assumes all the power carried the full 1000 miles. If power is supplied at 200 miles, the efficiency would be 90 per cent, etc. At 600 miles we have an efficiency of transmission of about 75 per cent. For distributed loads the efficiency would be higher.

The cost will not be prohibitive if we have a cheap source of power going to good markets as will be shown by the following:

The capital cost of power at the generating station we may take, say, at $150 per kw., and the transmission cost, including synchronous condensers and their transformers, may be $15 per kw. per 100 miles, or 10 per cent increase in the power cost for each 100 miles, or $300 per kw. (per kw. generated) for 1000 miles. But since the power delivered at 1000 miles will be about two-thirds, then the capital cost per kw. delivered will be $450. The above assumes 100,000 to 200,000 kw. (or more) transmitted per three-phase circuit, which may be successfully done (using aluminum for the smaller and copper for the larger power), as we shall see at 220,000 volts.

There may be a very large market, say five hundred miles from the power source, and the transmission system built for that condition. But another power load may be 50, 100 or 200 miles away and the justification for the added transmission must be that this step must pay the cost of the power at the end of the 500-mile transmission and all of the remainder of the transmission. Such a system may grow to a national power system.

220,000 Volts Proposed as Standard for Large Power and Long Distance

Since we can transmit at this voltage so large an amount of power (a thousand miles if economical) over one circuit, and a very large system would want for service insurance at least two tower lines with four circuits, giving a capacity of 400,000 to 800,000 kw. or more, it seems that for this reason it may be best to adopt 220,000 volts as standard for the national transmission system, just as the railroads have adopted a standard gage. It will be shown that so far as other restrictions are concerned we may go to higher voltages, but the economic limitations may be reached by 220,000 volts, when we consider the value of standardization, the service insurance of multiple circuits, the amounts of power available at certain places, or the demand of a given market.

Heretofore I have always said that we would go to higher voltages, but I now believe, for the above reasons, that 220,000 should be standard for extra high-voltage systems. And it would be advantageous if 220,000-110,000-55,000 could be generally adopted, in order that auto-transformation may be used economically.

A Standard National Electric Power System
Standard Frequency

To have a national electric power system requires first standardization of frequency. Since 60 cycles is generally advantageous for generators, transformers and distribution, I will assume that this is the frequency of the very long-distance transmission. It is generally assumed that this frequency is disadvantageous for long transmission lines on account of voltage regulation, but it will be seen that all regulation requirements can be very successfully met with 60 cycles. I therefore believe it will be best to standardize on 60 cycles.

Constant Voltage at all Points of Lines

It will be necessary for the successful long transmission line to have practically a uniform voltage for all points of the line—not only for one load but for all loads. This voltage can be controlled within 3 per cent from no-load to full load and with no greater variation for any points on the line. The standard transmission system must provide for power being supplied to the lien and for loads to be taken off at certain points, just as does a railway system. The system must be such that the power loads supplied to the line or taken from the line may vary and that the flow of power over sections may be actually reversed, or the flow of power over the entire line may even be reversed—without disturbing the voltage regulation necessary to give good service at all points. There is nothing experimental about the proposal as synchronous condensers for voltage regulation for fairly long lines were used as early as 1904 on what is now the system of the Pacific Gas and Electric Company, to regulate voltage in an emergency for transmission of power over 300 miles of line at 44,000 volts. The present plan differs from the ordinary plan in that synchronous condensers are located, say every 100 miles, and with these condensers the current and voltage would be maintained practically in phase.

It will be seen that the maintenance of constant voltage at all points is not a difficult matter and in doing this we get rid of a lot of other troubles and

expense,—such as voltage rise due to dropping loads, transformer variable ratios, voltage regulators, etc., *and reduce the insulation strain.* The successful very long lines must provide for keeping the current and voltage practically in phase at all points of line.

If engineers and operating men can standardize the frequency and the voltage so as to give constant service, and the insulation of the transmission lines is made so that the line is as successful as the transformers, then we may see the real era of very long, high-power transmission systems in the near future. The 220,000-volt lines now being built are therefore extremely important; and extreme care is being given to all the questions, not only in view of the importance of the lines being built, but also because of the effect on the service of these lines on the transmission industry as a whole.

Voltage Regulation of Transmission Lines*

It is necessary to decide on the voltage regulation of the system before we can know what ordinary and extraordinary strains may come on the insulation of the transmission line; hence this subject is treated first.

In Fig. 1 is shown the regulating diagram for a 200-mile, 220,000-volt line, for 400 amperes current. It is shown there that without synchronous condensers for a power factor of load of 0.95 the generator voltage would have to be 157 per cent of receiver voltage. At no-load the generator voltage would be about 86 per cent if all charging current is carried by generator. Even for non-inductive load the generator voltage at full load would have to be raised 36 per cent above receiver voltage. Now this extra generator voltage is part of the capacity of the generator and costs money. Restricting the generator voltage increase to the 10 per cent required to make up the dissipated energy on the line, requires synchronous condensers of about 80,000 kv-a. at full load, but about one-half this amount is required to correct the power factor of the load. In this figure and those following, the explanations are given with each case. Fig. 1 is given largely to show that it is impossible to transmit power over long distances and give satisfactory service without synchronous condensers.

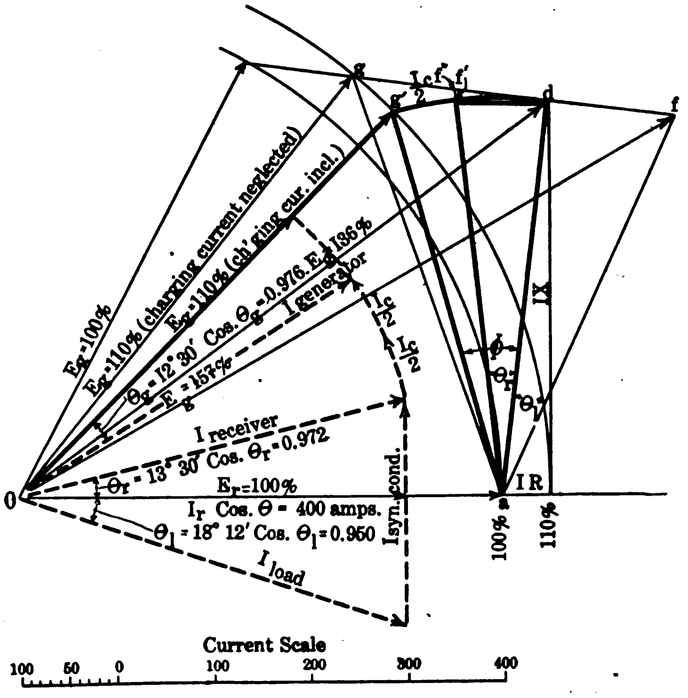

Fig. 1—Regulation of Line with Transformers at Each End

CONDITIONS:

Length of line = 200 miles. Receiver volts E_r constant at 200,000. Charging current 136 amperes.

I Cos θ at receiver = 400 amperes. Power delivered = 138,600 kw.

$I\,R$ pressure including transformers at each end of line = 10 per cent E_r (approx.)

$I\,X$ pressure including transformers at each end of line = 80 per cent E_r (approx.)

RESULT:

CASE 1. Charging current neglected. With no synchronous condenser at the receiver and a load power factor of *unity*, the generator voltage $E_g = o\,d$ = 136 per cent E_r = 272,000 volts at full load.

CASE 2. Charging current neglected. With no synchronous condenser at the receiver and a load power factor of 0.95 lagging, the generator voltage $E_g = o\,f$ = 157 per cent E_r = 314,000 volts at full load.

CASE 3. Charging current neglected. With a synchronous condenser at the receiver to maintain a generator voltage $E_g = o\,g$ = 110 per cent E_r = 220,000 volts at full load, the receiver power factor would be 0.89 leading (cos. angle *dag*.). The ratio $f\,g/a\,d$ gives the synchronous condenser current necessary to correct the power factor from 0.95 lagging to 0.89 leading (336 amperes approx.).

CASE 4. Considering one-half of charging current as supplied at each end of the line, and a synchronous condenser at the receiver to maintain a generator voltage $E_g = o\,g'$ = 110 per cent E_r = 220,000 volts at full load:

With a as center, draw circular arc $d\,g'$. The length of arc $d\,g'$ is equal to $a\,d \times \Phi$ (in radians).

The angle Φ measures 23 deg. = 0.401 radian. $a\,d = \sqrt{0.10^2 + 0.80^2} \times E_r = 0.806\,E_r$. $d\,g' = 0.806\,E_r \times 0.401$ = 32.3 per cent E_r.

The charging current $I_c\,X/2$ = 13.3 per cent (approx.), hence the correction to be made by the synchronous condenser is 32.3 − 13.3 = 19.0 per cent.

Lay off $d\,f'$ = 19.0 per cent E_r and draw $a\,f'$ and $d\,f'$. Note that the condenser current must be at right angles to $a\,d$, so for practical purposes we may use the point f'' instead of f'.

The power factor of the receiver is 0.972 leading (cos. angle $d\,a\,f''$). The ratio $f\,f''/a\,d$ gives the synchronous condenser current necessary to correct the power factor from 0.95 lagging to 0.972 leading (230 amperes approx.).

NOTE: Fig. 1 is given mainly to show that very long transmission without synchronous condensers is not practicable. The figure as drawn is not absolutely accurate except when $E_r = E_g$, but the error is not material.

Fig. 2 gives the fundamental basis for regulation for constant voltage by using distributed capacity, of such magnitude that the line current and voltage are always practically in phase. This makes the reactance pressure always tangent to the voltage circle, the reactance voltage being represented by the circular arc connecting the ends of the line pressures.

Fig. 3 shows that, for 60 cycles, 200,000 volts and 400 amperes transmitted, the line charging current gives full correction at about 0.8 load, and that the synchronous condensers at full load must supply capacity current of about one-half the charging current. Thus it is seen that the line supplies a large part of the charging current required for regulation. At loads below 0.8 the synchronous regulators supply lagging current. It would be preferable to call the synchronous condensers "synchronous regulators." (This proposal for regulation and the method of presenting it are new, so far as known.)

Thus it is seen that the transmission line has largely inherently the currents required for self-regulation, if we correct initially the power factor of the loads to near unity. Every induction motor added to the system calls for a certain capacity current for correction of power factor to reduce the losses from motor through the power station. Every synchronous motor added, instead of an induction motor, helps in the economy all along the line, improves the service and reduces the menace of large lagging currents. Every synchronous motor added becomes an asset to the entire

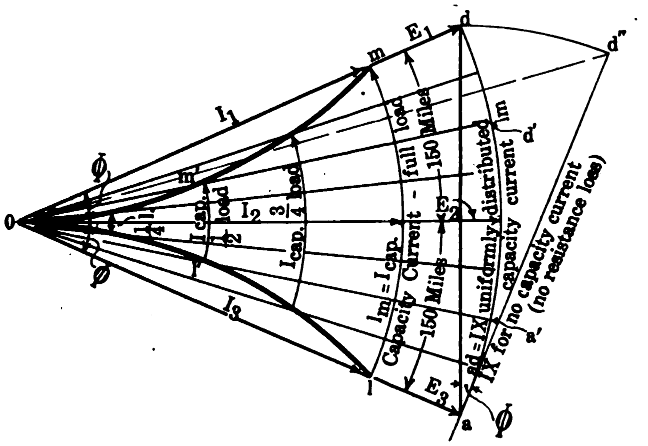

Fig. 2—Regulation of Line Alone

Uniformly Distributed Capacity Current to Correct Voltage at all Loads

CONDITIONS:

Length of line, 300 miles. Voltage at all points constant at 200,000. Charging current 200 amperes.

Energy current delivered to line, 400 amperes. Power delivered to line, 138,600 kw.

No resistance loss and no energy dissipated along the line.

$I\,X$ pressure equal to approximately 80 per cent E_3 and measured by arc $a\,d$.

RESULT:

If no power is lost along the line, then current $I_1 = I_2 = I_3$ and they are in phase with voltages E_1, E_2 and E_3, the power factor being unity. If reactance pressure is 80 per cent of E_3, then arc $a\,d = 0.80\ o\,a$ and angle $2\,\Phi = 0.80$ radian $= 46$ deg. (approx.). The uniformly distributed capacity current is everywhere at right angles to the voltage and the summation is shown by the arc $l\,m$. If $o\,l$ represents 400 amperes or the energy current, then $l\,m = 2\,\Phi \times o\,l = 0.80 \times o\,l = 0.80 \times 400 = 320$ amperes, the uniformly distributed capacity current necessary to maintain conditions as set down above.

At one-half load the reactance pressure, which corresponds to one-half load $a\,d$ is reduced one-half to $a'\,d'$. This reduces the angle between E_1 and E_3 by one-half. Since the current is reduced by one-half $o\,l$ is reduced to $o\,l'$ and the arc $l'\,m'$ becomes one-quarter the length of $l\,m$. Thus it is seen that the capacity current required varies as the square of the load current.

If there were no capacity current on the line at full load, then the reactance pressure would be $I\,X = a\,d''$ at right angles to E_3. The arc $d\,d''$ shows the voltage correction due to the summation of capacity currents flowing over the line reactance.

Note that the angle between $a\,d$ and $a\,d''$ is always equal to one-half the angle between E_1 and E_3.

CONCLUSION:

To have constant voltage at all points on the line requires that the capacity current uniformly distributed over the line be varied along the curves $o\,l'\,l$ and $o\,m'\,m$ from no-load to full load, this variation being as the square of the load current. This maintains the voltage and current practically in phase at all points of the line, and this condition is necessary for successful long-distance transmission of power.

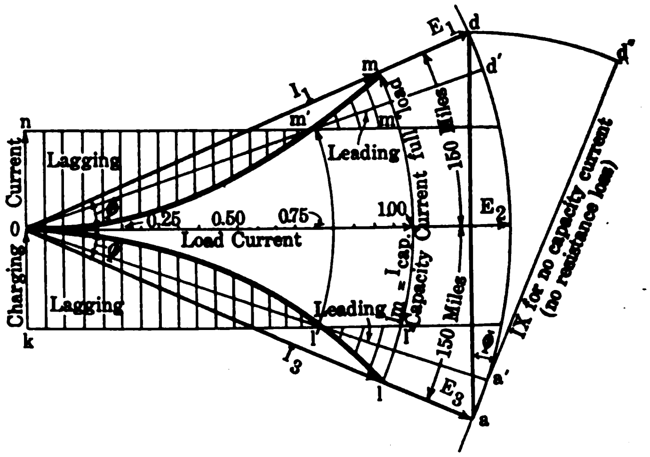

Fig. 3—Regulation of Line Alone

Line-Charging Current Supplemented by Uniformly Distributed Capacity or Uniformly Distributed Inductance.

CONDITIONS:

Length of line, 300 miles. Voltage at all points constant at 200,000. Charging current, 200 amperes.

Energy current delivered to line, 400 amperes. Power delivered to line, 138,600 kw.

No resistance loss and no energy dissipated along the line.

$I\,X$ pressure equal to approximately 80 per cent E_3 and measured by arc $a\,d$.

RESULT:

If no power is lost along the line, then load current $I_1 = I_2 = I_3$. The line-charging current is shown by the line $k\,n$ and is uniformly distributed along the line. At a point of approximately 80 per cent load, the line-charging current $l'\,m'$ furnishes a uniformly distributed capacity current, which makes the voltage equal at all points along the line. (See conclusion, Fig. 2).

From 80 per cent to full load uniformly distributed capacity current must be added to the charging current, as shown by the lines between $m'\,m''$ and the curved line $m'\,m$ and also between the line $l'\,l''$ and the curved line $l'\,l$. The power factor would be unity.

To correct accurately the voltage from no-load to 80 per cent load we would have to have distributed inductance, as shown by the lines drawn between $n\,m'$ and the curved line $o\,m'$ and also between the line $k\,l'$ and the curved line $o\,l'$. The power factor would again be unity.

CONCLUSION:

The above would give accurately the regulation desired, but we have no method of adding distributed capacity or inductance. The best we can do is to approach the desired result by adding synchronous condensers which may operate as capacity or inductance at the will of the operator.

NOTE:

Thus far we have not considered resistance losses, but they are easily taken into account as will be shown.

This adjustable "loading" of the line to maintain the current practically in phase with the voltage is comparable to the "loading" of telephone lines for long-distance circuits.

system. Power factor correction should be done largely at load centers, the final correction and regulation being accomplished by the transmission line capacity current and the synchronous condensers.

There are many places where synchronous motors could replace induction to great advantage. The electrical manufacturers and the power companies should cooperate in developing simplified types of synchronous motors for constant speed work.

The advantages of such a system are: Simpler and cheaper generators, transformers standardized for one voltage, insulation strains reduced and a safer system results, and with constant voltage the flow of power has the greatest possible flexibility.

Figs. 2 and 3 show that it is necessary for constant voltage at all points of the line that the voltage and current be maintained practically in phase. Fig. 4 applies these conditions practically to a 300-mile line and Fig. 5 to a line 800 miles long. The diagram is very simple and may be extended for any line length.

Conclusion

Such a system of constant potential transmission is practical, and is the only practical way of giving perfect service for long lines. Retransforming or regeneration or direct-current schemes for long-distance transmission will not give as good service and the shocks that are likely to come on the line are much greater than for the constant potential system. Such a system of "loading" the transmission line to rotate the current through approximately the same angle as the pressure is rotated is necessary for all very long distance transmission, thus causing the reactance pressure to be always tangent to voltage circle. This "loading" to maintain the current and voltage approximately in phase eliminates the question of the natural periodicity of the line, and hence the frequency may be selected independently of this point.

The voltage being constant there is a gradual decrease of current to make up the dissipated energy of the line. The angle between the generator and receiver voltages of a 150-mile section will be about 23 deg. at full load, 60-cycle, and the angle decreases per 150-mile section as the current decreases.

The power factor of line is good, being 0.99 or better from about 80 per cent to full load, and hence efficiency of line is 90 per cent for 200 miles, and 90 per cent for each section of 200 miles, with the result that power may be transmitted 600 miles with an efficiency of about 75 per cent and 1000 miles at an efficiency of about 65 per cent. For distributed loads the efficiency would be higher.

Such a system, with say three or four circuits, and synchronous condenser and switching stations about every 100 miles, may have automatic disconnection for any 100-mile section of each line without disturbing the service. Short circuits should be easily handled.

The synchronous condensers "tie down" the points of the system. Any tendency to raise or lower the line voltage is instantaneously counteracted by the condenser—in this respect acting like an "electric gyroscope."

Since transformers can be designed so that increase of line voltage gives a very rapid increase of magnetizing current, we have here, as well as in the synchronous condensers, automatic magnetic brakes acting against increases in voltage.

Corona losses increasing with voltage, if size of

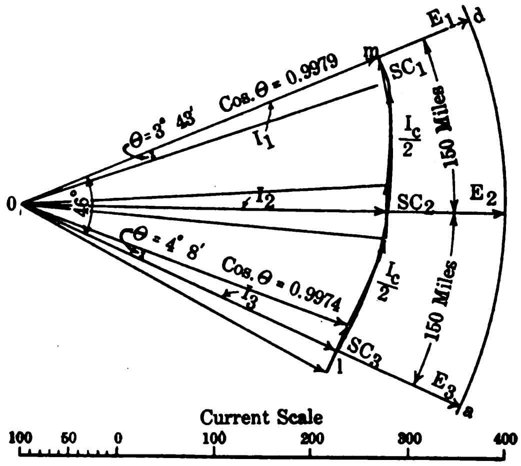

Fig. 4—Regulation of Line Alone

Leading or Lagging Current Added at Middle and Each End of Line

CONDITIONS:

Length of line, 300 miles. Voltage at middle and each end constant at 200,000. Charging current, 200 amperes.

Energy delivered to line, 400 amperes. Power delivered to line, 138,600 kw. Total energy loss including $I R$ = 10 per cent.

$I X$ pressure equal to approximately 80 per cent E_1 and measured by arc $a d$.

RESULT:

Since the arc $a d$ is 80 per cent of the radius $o a$, the angle $d o a$ is 0.8 radian = 46 deg. (approx.).

Since the voltage at each end of the line is constant, the energy loss will appear as a reduction in load current, diminishing in direct ratio to line length, hence if $I_1 = 400$, $I_2 = 0.95 \times 400 = 380$, $I_3 = 0.90 \times 400 = 360$.

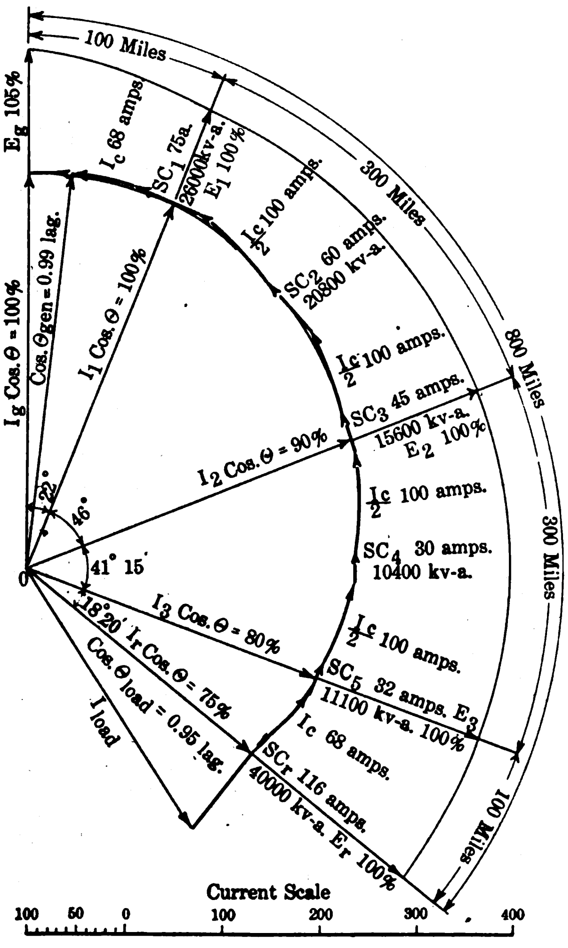
The curve $l m$ represents a uniformly distributed capacity current which will give equal voltage at all points on the line at full load. The length of $l m$ is approximately equal to $380 \times 0.8 = 304$ amperes. The charging current supplies 200 amperes of capacity current, leaving 104 amperes to be supplied by synchronous condensers. One-half of this is to be supplied by a synchronous condenser in the middle of the section, one-quarter by the generator, if this is the first section of the line; and if not, by the synchronous condenser at the end of the section toward the power house. The remaining quarter is to be supplied by a synchronous condenser at the far end of the section. This synchronous condenser, however, will be the same capacity as the one at the middle of the section, the excess capacity to care for load power factor correction if it be the terminus of the line or to furnish the initial capacity current required in the next 300-mile section of line. This makes the condensers 18,000-kv-a. $(52 \times 200{,}000 \times \sqrt{3})$ capacity, or say 20,000-kv-a. to afford a safe margin, for each 150-mile section of line where there are no transformers or other apparatus to change the $I R$ and $I X$ pressures as set down above. If transformer resistance and reactance are included, the diagram will have to be modified to fit a section of line enough shorter than 300 miles, so that $I X$ and $I R$ including transformers are 80 per cent and 10 per cent respectively. This lowers the charging current and increases the size of synchronous condensers required for the section. In considering the 300-mile section, the transformers for the synchronous condensers are small and the magnetizing current will be supplied by the condenser. The section is considered as if no transformers were present.

The voltage on a 300-mile section at no-load varies less than 1 per cent, if the charging current is supplied one-half at the middle and one-quarter at each end of the line. The power factor at each end of the 300-mile section will be practically 0.99 and the entire section will have a power factor between 0.99 and unity, from 80 per cent to full load. (See Fig. 3).

wire is chosen near the corona point, will also automatically act against increases of speed and voltage.

The voltage strains on insulators, switches and transformers of such a system will be much less than where the constant potential control does not exist, and hence we very largely solve the insulator problem by the voltage control.

The "loading" of the line with transformers designed for a rapid rise in magnetization with increases in voltage, the transformers having secondary or tertiary windings connected delta, connected to synchronous condensers at proper distances, will reduce the insulation rises so that 220,000-volt lines will have less insulation overstrains than present high-voltage lines. Adding to this the improvement to be obtained by decreasing the duty on the line wire insulator units, assures the success of very long transmission lines—practically removing the distance limitation to electric transmission. This method of transmission also eliminates the necessity for further consideration of d-c. transmission as the a-c. system has the advantage of the constant-voltage feature, for any conditions of loads and power supply, and has other advantages over the d-c. system.



CONDITIONS:

End sections of line each 100 miles long. *I X* pressure including transformers, 40 per cent. *I R* pressure including transformers, 5 per cent. Charging current, 68 amperes.

Intermediate sections of 300 miles length. *I X* pressure, 80 per cent. *I R* pressure, 10 per cent. Charging current 200 amperes.

Full-load generator volts, 105 per cent E_r. Voltage constant after first synchronous condenser station.

I cos θ at generator is 100 per cent. *I* cos θ at first synchronous condenser station is 100 per cent and then decreases uniformly along the line to care for energy losses. (Note that cos θ varies only slightly from unity, and that the current tapers from 100 to lower values to make up resistance losses as shown.)

RESULT:

Generator Section: See Fig. 1 which shows a 200-mile section with generator and transformers at one end and condenser and transformers at other end. Apply the generator end one-half of Fig. 1 to this case, modifying it as to generator voltage and consider that the generator carries only one-quarter of the capacity current instead of one-half as shown, the other one-quarter to be supplied by the first condenser in the adjoining section.

Second Section: Conditions exactly as in Fig. 4.

Third Section: Current is now 90 per cent *I*, hence the *I X* pressure is 90 per cent of its value in section two = $0.90 \times 0.80\ E_r = 0.72\ E_r$. The arc length representing this pressure is therefore reduced and the angle becomes 0.72 radian = 41 deg. 15 min. The capacity current required is 360×0.72 = 260 amperes (approx.). The charging current is 200 amperes, leaving 60 amperes to be supplied by the condensers as in section two.

Receiver Section: Current is now 80 per cent *I*, hence the *I X* pressure is 80 per cent of its value in the generator section = $0.80 \times 0.40\ E_r = 0.32\ E_r$. The angle now becomes 0.32 radian = 18 deg. 20 min. The capacity current required is 320×0.32 = 102 amperes (approx.). The charging current is 68 amperes, leaving 34 amperes total to be supplied by the condensers at the ends of the section.

If the load power factor is 95 per cent lagging, then the terminal condenser current will have to be increased by 99 amperes to rectify this load, and the kv-a. capacity would be $(17 + 99) \times 200{,}000 \times \sqrt{3} = 40{,}000$ kv-a. approximately.

NOTE: Power may be delivered to or from the line at any point. The load currents and synchronous condensers may be readjusted to care for the new conditions so that the voltage may remain practically constant. The power flow of the entire line may even be reversed and the constant voltage conditions retained.

FIG. 5—REGULATION OF COMPLETE TRANSMISSION SYSTEM

II. INSULATION OF TRANSMISSION LINES

The early transmission systems used the pin type of insulator, and lines up to 80,000 volts successfully used this type. Then the demand for higher voltages brought out the disk suspension insulator. Mechanically the disk insulator at first view seems an impossibility. But the insulator men have solved the difficulties and deserve a great deal of credit for the result. Suspension types can now be made with ultimate strength of 7000 to 20,000 lb.

The insulator men have carried a large burden during the development period of the insulator. Sometimes this burden is made greater by the engineer or operator asking for some particular design which may not be as good as standards already made. The desire of the individual to write his name on something is at the bottom of many failures in engineering as well as along other lines of human endeavor. On the other hand pioneer work is required when conditions change and designs must follow fundamental laws.

When the type of insulator for the high voltages changed to the disk type, it was assumed that the addition of more voltage merely required more units. But it was soon found that the results were not at all in proportion to the number of units in the string.

Investigating the cause it was found that the voltage tended to "pile up" on the line unit.

A very large number of tests has been made on voltage distribution, with various arrangements of controlling gradient, and also to determine the arc-over characteristics, both dry and wet, for various control arrangements. These tests were made in the following places and under the supervision of the following men:

Stanford University, Cal. Prof. Harris J. Ryan.

General Electric Co., Pittsfield, Mass. F. W. Peek, Jr.

Ohio Insulator Co., Barberton, Ohio. A. O. Austin.

Thomas & Sons, Lisbon, Ohio. R. H. Marvin.

Locke Insulator Co., Victor, N. Y. K. A. Hawley.

Westinghouse Elec. & Mfg. Co., Pittsburgh, Pa. C. Fortescue.

I very greatly appreciate the interest shown by these men and acknowledge with thanks their hearty cooperation.

In the following pages the insulation problem is discussed in some detail, and the discussion is followed by an appendix giving the results of a large number of tests, the conditions for which are stated. Only a few of the tests made are given.

Insulation of Transmission Line

In the insulation for transmission lines we must consider the following:

1. The air insulation strength.
2. The porcelain insulation and mechanical strength.
3. The voltage distribution.
4. The leakage resistance gradient over the surface of the insulators.
5. Insulation of switches, transformers, etc.
6. Wet and dry arc-over of line insulation.

1. The Air Insulation

Engineers and operators have been prone to blame the insulation difficulties on the air. But as a matter of fact, air is, except where we have salt spray, etc., a very good insulator. Peek (whose work on Dielectric Phenomena is a classic in engineering) has shown in his book that it requires only about three inches of air between 10-inch spheres to prevent break-down for 130,000 volts to ground, which is about the voltage to ground for a 220,000-volt line. Two 20-inch spheres, spaced two feet, give a factor of safety of about four. We are using over six feet from wire to ground at the towers (15 feet between wires in the span), but we do not get a factor of safety commensurate with the distance.

With wires about 1 inch in diameter we need never fear break-down of the air between the wires a few feet away from the insulators, and if it were not for the reduction in the equivalent spacing at the tower, due to the insulator breaking the distance into a number of parts, with unequal stress on the separate units, we could reduce our spacing in the span and thereby reduce the height of the towers.

Fig. 6 shows the voltage air gradient for a wire 0.91 in. in diameter at 220,000 volts, and also the gradient for a wire 0.47 in. in diameter for 110,000 volts. It is seen that the gradient is very high near the surface of the wire, and very nearly the same in the two cases. The break-down value of air is about 20 kv. (effective) per cm. (The size of line wire is purposely chosen so that increases of voltage much above normal will increase materially the corona losses, as this is a safeguard in case of rise in voltage due to speed rise or otherwise). At a distance four cm. from the surface of the 220,000-volt wire the gradient is only about 4 kv. per cm. In the span, away from the insulators,

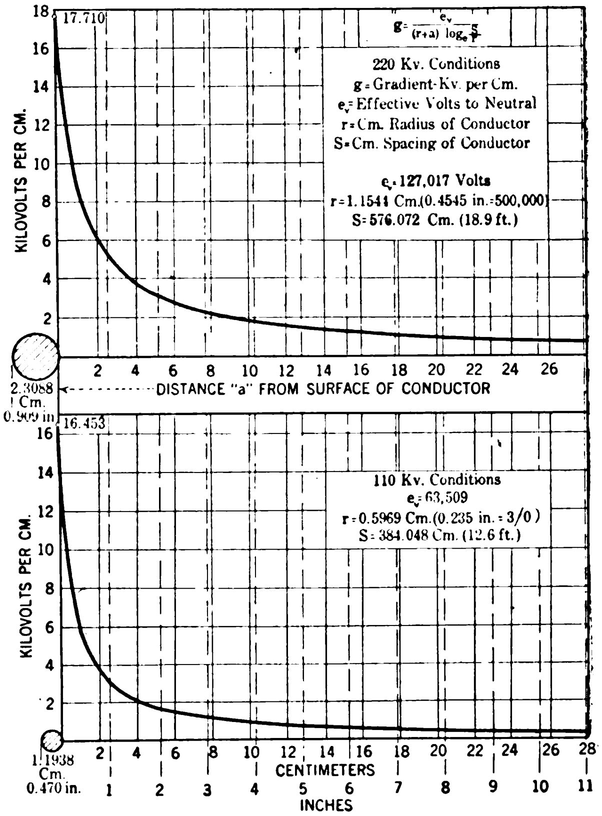


Fig. 6—Air Gradient for 220,000- and 110,000-Volt Conditions

any tendency to produce visual corona has the effect of enlarging the effective diameter of wire so far as surface gradient and break-down are concerned, hence the air in the span does not break down for any voltages that may be reached in operation.

Coming now to the line clamp fittings and insulator pin of the first unit, we see that we have here very high air gradient, due to small diameters, angles of bolts, fittings, and also due to the small pin of the bottom insulator. When excess voltages come on the line they pile up most of it at the insulator units near the line wire. This breaks down the air where it is highly stressed at the line fittings, and the air breaks down serially from one unit to another, by transferring the high electric stress from one

unit to another in the string. (Corona also forms acids which attack the metal fittings.) It is necessary to prevent incipient corona pluming or arcs at the insulators, if the transmission line is to be fully successful—by which I mean the insulation of the line must be such that the line should give as good operating results as the transformers or other transmission apparatus. Of course, the line is subject to damage maliciously, or due to accident, but neglecting these, the line should be made as reliable as the remainder of the system.

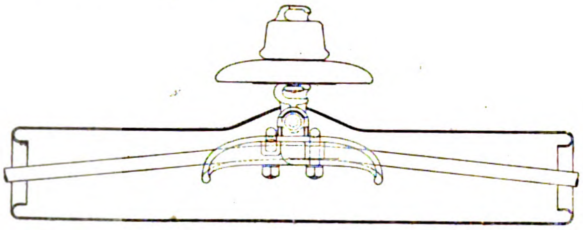

FIG. 7—LINE SHIELD

Attempts made to reduce the air grading at the pin and fittings by the use of "shields" (these will be explained later) have led to fairly satisfactory results. And it seems necessary to shield the line wire and fittings by enlarging the conductor diameter by some such cylindrical (or double cone or plane) shield as shown in Figs. 7 and 8. With such a shield the visual corona near the insulator may be raised far above the operating voltage. The fittings of the insulators of the string should also be designed to prevent high air stress.

2. THE PORCELAIN INSULATION

Porcelain when well made is a good insulator, and will not puncture under the stress conditions placed on it, if the other elements in the insulation are cared for. The metal fastenings to the "cap and pin" disk types of insulators add a mechanical depreciation factor because expansion and contraction are not the same for the porcelain and the metal parts, and the cement used to fasten the parts together. By careful manufacture, a very tough porcelain can be made, in which depreciation from expansion and contraction can be very much reduced. Careful selection and working of the clay, and sufficient time in firing, give a very high-class insulator product.

Impregnating the cement, to prevent absorption of moisture, has given good results, according to Mr. E. E. F. Creighton. Some means of keeping the moisture out of the cement, and careful mixing and setting of the cement initially, will no doubt reduce the mechanical failure due to these causes to very low values. I have always contended that we should finally obtain insulators that do not depreciate.

In the link type of fastening the mechanical depreciation from expansion and contraction is very largely reduced, but in the types now made we are restricted to small diameter of metal parts, and it is necessary on high-voltage lines to shield the links—at least those in the lower part of the string. (Fortunately this also improves the grading of the string as will be seen later).

The depreciation, due to expansion and contraction, is largely one of cost, and as it is a slow process and we have a factor of safety in the number of units in the string, we may dismiss the mechanical failure from the above causes as not affecting good service with good inspection.

The mechanical strength of all the standard insulators is from 7500 to 10,000 lb. and over, and these can be increased 50 or 100 per cent, where necessary, so that we have ample factor of safety for the mechanical suspension of the line wires.

3. THE VOLTAGE DISTRIBUTION FROM LINE TO GROUND

Figs. 12 and 13, and plates, D1, D2, D3 and D4 in the appendix, show the voltage gradients for cap and pin insulators and also for the link type. It is seen that, for the voltage corresponding to that between line wire and ground, the total pressure is divided very unevenly among the units. In the cap and pin string of 14 units the volts on the line unit are about 25,000, or about 2.5 times the average, but about six times the volts on the units near the ground end.

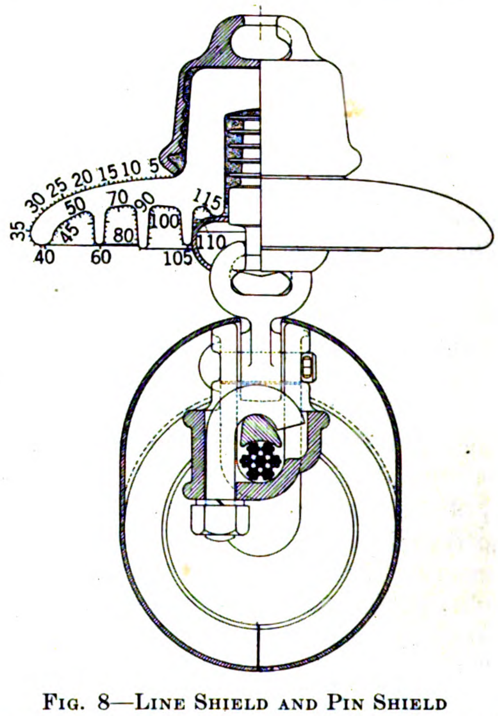

FIG. 8—LINE SHIELD AND PIN SHIELD

Numbers on edge of porcelain are for measuring leakage paths. (See Fig. 14.)

In the link type as shown, we have even a worse case of distribution of pressure, the maximum being about 37,000 or four times the average, and about ten times the stress on the units nearer the ground end of the string. This unequal stress on the units also causes unequal stress on the air, *but most important it does not distribute the leakage resistance along the string uniformly*. The maximum air and leakage stresses are from six to ten times the average. Reduc-

tion of the maximum stresses is therefore very important, and the result desired is that there will be more nearly average resistance stresses over the entire string, for the worst practical conditions.

Discussion of Cause of Poor Gradient and Method of Cure. Before we can say we fully understand a subject we must be able to express the facts in words mathematically or by diagram. Before we can rationally analyze an insulator we must know the factors which will limit the maximum stresses, which are:

1. The air stresses,
2. The leakage resistance stresses,
3. The insulator unit stresses.

The air stresses we know, as shown by Fig. 6, and to control this factor we must enlarge the conductor at the insulator, as shown in Figs. 7 and 8. The first controlling factor for satisfactory insulator characteristics then is that we must have metal parts designed to give low air stresses at the line wire, and also along the string of insulators, at least near the line wire end.

The unit stress affects the leakage stress and therefore it is very important also from this standpoint to reduce the maximum unit duties. The maximum leakage stress can be reduced (1) by reducing the unit voltage and (2) by enlarging the pin as shown in Fig. 8, and by the design of the resistance path from metal to metal as shown in Figs. 14 and 15. The enlargement of the pin and the shield over the line wire also reduces the maximum voltage on units near the line. The importance of reducing the maximum value of the leakage gradient is shown by the fact that in the pin type of insulator with the close fitting inner shell, better operating results are obtained by breaking off the inner shell. Here is one way of reducing the maximum leakage gradient, but the design should take this into account. This will be further discussed under (4): The Leakage Resistance Gradient over the Surface of the Insulator.

Hence, we have these two factors, (1) the enlargement of line wire and metal parts, and (2) the enlargement of pin, to start with to give us a satisfactory insulator. As will be seen, taking care of these two points helps the grading of the units fairly well.

The third factor, the grading of the units, requires that we be able to understand the reasons for the string gradient.

An attempt to explain this is here given in such a way that the drawing of a few lines may show the characteristic of any insulator string, knowing certain factors relatively only. It is not contended that we have all the facts necessary to explain every condition, but the method does give a simple and practical way of explaining many of the observed results, and it is hoped that the method given will lead to a further study of the subject, so that we may design or analyze the design of insulators in the same way as any other engineering problem.

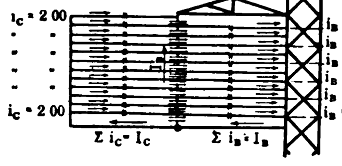
Figs. 9A, 9B, 9C and Table 9D give the explanation which results from a study of the distribution curves shown in Figs. 10 and 11.

(The individual insulator string may be regarded as a short section of transmission line with the Y voltage between ends, and with load currents, B, taken off at the different sections (or units) and load currents, C, being supplied to the sections. The load currents, B, depend on the voltage at the particular section.)

Referring to Fig. 10, which is a voltage distribution test curve of 14 cap and pin units, as shown by Curve I, this curve represents the voltage across the units, but as the voltage is proportional to the currents through the units the curve also represents, on some scale, the currents. Now the difference between the current through No. 14 and No. 13 units, for example, is the *net* current from the metal connecting parts to tower or ground. Taking the differences of the voltages and plotting them from the line $a\,a'$ we get the Curve II, which represents the net currents flowing from or to the string. It will be noted that below the fifth unit the currents flow from the string and above that point the currents flow from the air to the string.

In trying to find a physical explanation for this condition we draw the insulator string gradient and the air potential gradient on the left hand of Fig. 10, and from the knowledge gained from Curve II we see that where the net current from the metal part is zero the string potential and the air potential must be the same. Also we see that the summation of currents above the line where distribution Curve I cuts the average voltage, must be zero and that the current $c'\,a'$ at the top cap must be due to the current flowing to the cap only, as this cap is at zero potential. From this and from calculation of the potential drop through the air near the line wire (which we know follows a logarithmic curve) and from the fact that the air potential reaches zero at some distance above the crossarm in the span, we draw the approximate air potential. The difference between the air and string potential causes the currents to flow to or from the string as in Curve II.

We know that the currents from the metal parts to tower or ground would be approximately proportional to the voltage and hence a line $a'\,b$ may represent this current. Replacing the curved line II by the straight line III for simplicity of treatment and now calculating the gradient, we get Curve IV which approximates Curve I fairly closely. At the lower unit, due to the high electric stress, there is added potential to the lower unit. The difference between the line $a'\,b$ and $c'\,c$ represents approximately the currents from line wire to metal parts. This is the experimental basis for the discussion given in Fig. 9, in which 9B is supposed to represent the physical conditions, 9A the electrical and 9C the diagrammatic conditions. Fig. 11 gives the experimental results for the link type of units.



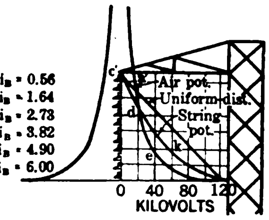


FIG. 9A FIG. 9B

ANALYSIS OF DISTRIBUTION CURVES

Fig. 9a shows an approximation of the different current paths with relation to the insulator string. Fig. 9b shows the potential. The curve of air potential shows the difference of potential between the surface of the conductor and the air at any given distance from the conductor. The straight line marked "uniform distribution" is the potential curve we would get for the insulator string if the voltage drop were uniform along the string. The curve marked "string potential" shows the actual voltage along the string from tower to conductor. Below the point d the air potential is lower than the string potential, causing a flow of current *from* the string, while above the point d the reverse is true and current flows *into* the string. This gives the line $c'\,c$ of Fig. 9c showing the difference between the B and C currents.

Inspecting the several currents shown in Fig. 9a, we have:

First: I_A which is the series current flowing through the string. This current varies as the voltage across the string and inversely as the number of units in the string. For convenience, we will assign a value of 10 to this current in a string of 12 cap and pin-type units with a duty of 10 kv. per unit or 120 kv. or the string.

Second: I_B which is the capacity current from cap to tower or ground, varying directly as the voltage between cap and ground. In a string of 12 cap and pin-type units where I_A is taken as 10, i_B, the current per unit, will vary from zero on the cap attached to the tower to approximately 6 on the cap of the unit next to the wire. I_B flowing in the string at any point is the summation of the currents from all caps between the point considered and the grounded end of the string.

Third: I_C which is the capacity current from the wire to each cap. Since the impedance path consists principally of the impedance of the air between the line and unit, and then in series through the insulator string, it is practically constant. In a string of 12 cap and pin-type units where I_A is taken as 10, i_C, the current per unit, will be approximately constant at 2. I_C flowing in the string at any point is the summation of the current to all caps between the point considered and the grounded end of the string, and may be considered as of the opposite sign to current I_B, because of the fact that the current is arriving *on* the insulator cap from the wire, and not flowing *off* the cap to tower or ground. (Note: Currents from cap to cap practically balance.)

TABLE 9D

Unit	Series Current in String I_A	Capacity Current Cap to Tower I_B In unit	I_B In string	Capacity Current Wire to Cap I_C In unit	I_C In string	$I_A + I_B - I_C$ In string
1	10	0	0	2.00	2.00	8.00
2	10	0.55	0.55	2.00	4.00	6.55
3	10	1.09	1.64	2.00	6.00	5.64
4	10	1.64	3.28	2.00	8.00	5.28
5	10	2.18	5.46	2.00	10.00	5.46
6	10	2.73	8.19	2.00	12.00	6.19
7	10	3.27	11.46	2.00	14.00	7.46
8	10	3.82	15.28	2.00	16.00	9.28
9	10	4.36	19.64	2.00	18.00	11.64
10	10	4.90	24.54	2.00	20.00	14.54
11	10	5.46	30.00	2.00	22.00	18.00
12	10	6.00	36.00	2.00	24.00	22.00

Table 9d shows the result obtained by using the values given above for I_A, i_B and i_C, that is 10, zero to 6 and 2, and applying to a string of 12 cap and pin-type units. The voltage duty is assumed as 10,000 volts per unit or a total of 120,000 volts for the string, and since the potential difference is proportional to the current flowing, we have a measure of the unit voltage duty when we know the current flowing. By taking the values of 10, 6 and 2 instead of some other set of numbers bearing the same ratio, the summation curve when plotted as in Fig. 9c, may be read directly in kilovolts duty per unit.

The relative values of the A, B and C currents as taken above hold good for cap and pin-type units when the unit voltage duty averages 10,000. For the Hewlett type insulators the B and C currents are approximately the same as in the cap and pin-type units, but the series capacity of the Hewlett is approximately only two-thirds that of the cap and pin type, hence keeping I_A at the same value of 10, the B and C values will be relatively larger and the ratio becomes $A : B : C = 10 : 0$ to $9 : 3$. From this relationship a curve for a string of Hewlett-type insulators similar to the curve in Fig. 9c may be plotted.

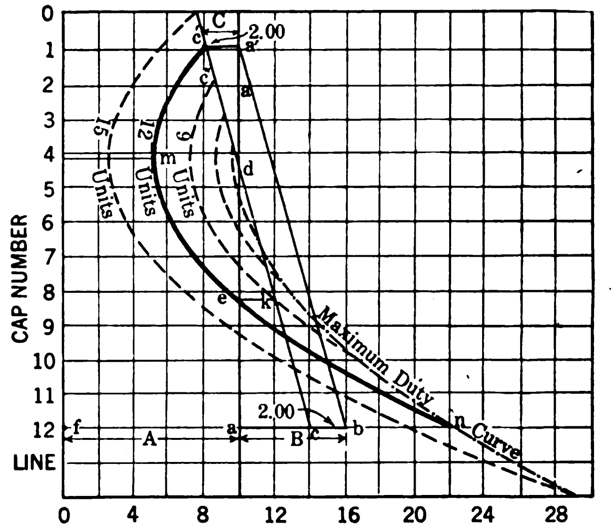

FIG. 9C

ANALYSIS OF DISTRIBUTION CURVES

To plot the voltage distribution curve lay off $a\,a' = I_A = 10$, a constant value for each unit. Next lay off $a'\,b$ such that $a\,b = i_B = 6.0$, thus making i_B vary from zero to 6.00. Next lay off $c'\,c$ to the same slope as $a'\,b$ so that $c'\,a' = c\,b = 2.0$. The distribution curve is now found by adding the values represented by $a'\,a$, a constant, and the values of $c'\,c$ as a s mmation, and is shown by the heavy line marked 12 *units*.

NOTE: In all discussions the B and C currents have been considered as varying along a straight line law. This, however, is not strictly true. In plotting the curve in Fig. 9c, it is seen that the line $c'\,c$ represents the *difference* between the B and C currents, and experiments have demonstrated that this *difference* follows closely along a straight line law. For the sake of simplicity, therefore, all have been considered as straight lines.

The point of minimum duty occurs at approximately one-third the distance from tower to conductor, and the voltage duty curve crosses the average duty line $a'\,a$ at a point e such that area $c'\,a'\,d$ is equal to area $k\,e\,d$. This means that above the point e, the voltages are balanced and therefore the only part of the string requiring grading is the unbalanced lower one-third.

Having given the curve for 12 units, the curves for other length of string where the duty remains the same average value of 10,000 volts per unit, may be drawn in for comparison. Since the minimum duty point is always about one-third the distance from tower to conductor, we may consider one-third of the change in length as applied at the tower end of the string and two-thirds at the line end.

The A current will remain at 10 as before since the total voltage across the string bears the same ratio to the number of units. The slope of $a'\,b$ will remain 6/11 as before because the rate of voltage change will not be altered. If we shorten the string by three units, taking one unit from the top and two from the bottom in order to keep the minimum point still one-third of the distance from tower to line, the value of the B current in the bottom unit will be $i_B/(11-3) = 6/11$ making $i_B = 4.36$. The ratio of the B current in the line unit to the C current is three to one, hence i_C becomes 1.45 and the first point on the curve for a nine-unit string is $c'' = 10 - 1.45$. Similarly we may plot a six or three-unit curve, or increasing the string length, a 15-unit curve.

Improving Distribution by Grading: As shown by 9c and by Figs. 10 and 11, the summation of the currents (B-C) from or to the string are balanced above e, the point where the curve cuts the average line. If therefore we grade the units below e to bring the voltage of these units to near the average, then the upper part of curve will rotate to the right around e as center, or the curve above e will move horizontally to the right, due to stress taken from the lower units being added to the upper units, thus improving the entire string distribution. It is found this can be done very well by making the four lower units larger as so to give larger pins and adding to capacity by fixed shields around pins. This also reduces the leakage resistance stress on lower units.

Improving Distribution by Shielding: By raising the air potential opposite the lower units, the C currents may be increased and the B currents decreased. This improves distribution, but it also has effect of adding to air potential higher up and this increases the currents to the upper part of string, and the dry arcs tend to go to ground through the upper third of the insulator string. Note Figs. 28 and 29. Raising the line wire potential above the lower units is also objectionable for several practical reasons.

While not considered exact, the analysis does help us to understand the insulator problem.

Satisfactory voltage distribution may be obtained, as shown by Figs. 9, 10 and 11 and also by Figs. 12 and 13 and the distribution curves in the appendix:

1. By use of ring shield,
2. By use of insulated horn shield,
3. By grading the lower one-third of the units,
4. By combining pin-type insulators at line end with disk-type for the upper end of string.

Methods 1 and 2 are very similar and accomplish the result by control of the field, by reducing the B currents and increasing the C currents. (The B current refers to the current from metal parts of units to tower or ground and the C currents to the currents from line wire to metal parts of units, as shown in Figs. 9, 10 and 11). The disadvantage of raising the air potential above the units is that this also increases the C or line currents to the upper part of the string. And the dry arcs tend to break into the upper third of the string. (See Figs. 17 and 18.) By the use of the pin shields and line shield, the height of the ring or horn shield may be reduced and part of the objection to the shields removed.

By method 3 we keep the potential of the string as high as possible above the air potential, and hence tend to prevent the arcs from breaking into the string. By using four large diameter units, with larger pins to increase the electrostatic capacity at the line wire end, and by using the line shield, we get a very simple string. It is possible to use the four large units and a low ring or short insulated horn shield to further grade the lower two units, if desired. By this method the size and height of the shield as used in method 1 and 2 would be reduced, thereby making the shield less objectionable. The air potential gradient from line wire to tower should be made as flat as possible, as a steep gradient invites arcs. This means a long string; and the air potential due to the line wire should be as low as possible.

By method 4 the string potential is brought close to the air potential. This method is merely given here as a possible method, as it has not been worked out practically. No doubt other methods combining the present disk insulators with larger units at the line or with bushings or other types at the line end will be worked out.

Under wet conditions the potential distribution of the string improves materially. But the most important condition is the leakage distribution with dirty insulators as they become wet or dry.

Because of the large leakage surface and the low cost, and the conditions of the electric field in the upper two-thirds of the string, the present disk type of insulator meets the problem of the upper two-thirds of the string very well indeed.

I have no doubt the insulator men will work out a satisfactory solution for the insulators near the line wire, and *reduce the leakage resistance stresses* and *the air stresses* to less than one-half of those now prevailing on 110,000 to 175,000-volt lines. This is necessary in order to give a satisfactory operating string, in my opinion. Let all work to that end.

With the ungraded string the factor of safety is

at the tower end instead of at the line wire end of the string. We should treat each insulator string as we have the end windings of transformers, not add more turns (or add more units), but increase the insulation or decrease the voltage stress on the units near the line wire, so that these can absorb the excess voltages due to switching etc., without undue stress. This can be accomplished by making the lower one-third of the units larger, with internal electrostatic capacity added to reduce the voltage, and by the use of a low external shield, which latter may be combined with a pin and line shield to reduce the stresses on the lower unit to satisfactory values.

4. The Leakage Resistance Gradient Over the Surface of the Insulator

In Fig. 14 is shown the theoretical resistance gradient for the standard insulator shown in Fig. 10, for the standard pin, and for 23,000 volts between cap and pin. It will be noticed that the resistance near the pin is very high and drops very rapidly in the first inch, due to the increase in the area of the leakage path. By enlarging the pin diameter we may reduce the maximum gradient near the pin very materially and increase the voltage gradient of the remainder of the insulator only a small amount as shown. The shaded area R 10 is equal to the sum of shaded areas $r_1 + r_2 + r_3$, etc. This result should be approximately realized if we short-circuit the part of the leakage resistance path near the pin as proposed by the use of the sleeve shield around the pin, as shown in Fig. 8.

Fig. 15 (data from tests by Prof. H. J. Ryan) is very interesting, showing that for the ungraded or unshielded unit we get actually a higher voltage at the edge of the disk than we do at the cap. This is no doubt due to the flux density near the line wire. We actually get 19,000 volts on the first inch of the leakage surface.

By short-circuiting to the first petticoat and putting a shield over the line wire, the voltage gradient is reduced one-half. By short-circuiting two petticoats we get a much better curve as shown by V and VI. Further study along this line is advisable.

The distribution of the resistance leakage stresses over the string and over each unit as uniformly as possible is, of course, the thing finally desired, and this is the main reason for striving for good string distribution of voltage. It is desired that the distribution remain as uniform as possible *for all conditions occuring in operation.*

5. Insulation of Switches, Transformers, Etc.

In the early days of electric power transmission the transformers, switches, etc., were housed to protect them from the elements. As the number of substations increased it was found often that the expense of housing the apparatus cost more than the apparatus. Hence there was developed outdoor apparatus.

The very large amount of space required for the 220,000-volt substation switches, etc., of course, makes it advisable to use outdoor apparatus so long as the total cost is less than where it is protected from the elements. Probably transformers and disconnecting switches can be more economically placed outdoors than in a building. But the oil switch may give a different conclusion on account of the fact that the enlargement of the bushings for the outdoor use also enlarges the tanks more than otherwise necessary, so that due to the increase in the bushing the cost of the switches for a given kv-a. capacity may vary somewhat as the square of the voltage, if all the elements of design are carried out consistently. That is, a switch for 220,000 volts may cost nearly double the cost of a switch for 150,000 volts due to the increase of the tank and oil, etc., as a result of the increase of the size of the bushing.

Now the size of the bushing is largely determined by the *wet* arc-over condition. A bushing for a 165,000-volt switch has a dry arc-over of about 480,000 to 520,000 volts. The wet arc-over of a 220,000-volt bushing will be around 400,000 to 450,000. (The wet arc-over for a 165,000-volt bushing is about 350,000 volts.)

That is, by keeping the 165,000-volt switch, when used on the 220,000 lines, dry and clean, we have a greater factor of safety than we have for the 220,000-volt switch when used outdoors. And since the 165,-000-kv-a. switch will give all the rupturing capacity required, it will pay to use this type enclosed, if the cost of protecting it from the weather is less than the extra cost of the higher voltage switches. Of course all the above assumes that ample clearances are provided.

This point does not come up in the case of transformers

127,000 volts duty on all three strings.

Tests by H. J. Ryan.

because the tanks are so large that the larger bushing cost is the only extra item to consider for the higher voltage. If the wet arc-over were increased by increasing the length and not the diameter, it would reduce the size of tanks, etc.

Especially in view of the present development of the art of high-tension switches, we should not expend more for switches than necessary at this time.

Hence, the protection of the oil switches from the weather should be given careful consideration. In this connection it may be noted that the wet 60-cycle arc-over for a 14-unit clean string of disk insulators will be about 450,000 to 550,000 volts, but of course, under outdoor conditions, due to dirt, etc., the arc-over voltage will be lower. We want the switches, of course, to have a higher factor of safety than the line units. Roof protection only may be sufficient.

6. Wet and Dry Arc-Over of Line Insulation

High-Frequency Arc. The control of the high-frequency arc can be effected as shown in Figs. 16 to 29. These tell their own story. The metal ring shield also gives satisfactory high-frequency arc control. That we need not worry about high-frequency arcs is shown by these illustrations, Figs. 18-21.

60-Cycle Dry and Wet Arc-over. The dry arc-over voltage for a 14-unit string of insulators, shielded with ring or insulated horn shields, is about 700,000 volts, or 50,000 volts per unit. The arc clears the insulators fairly well, but sometimes breaks into the upper third of the string.

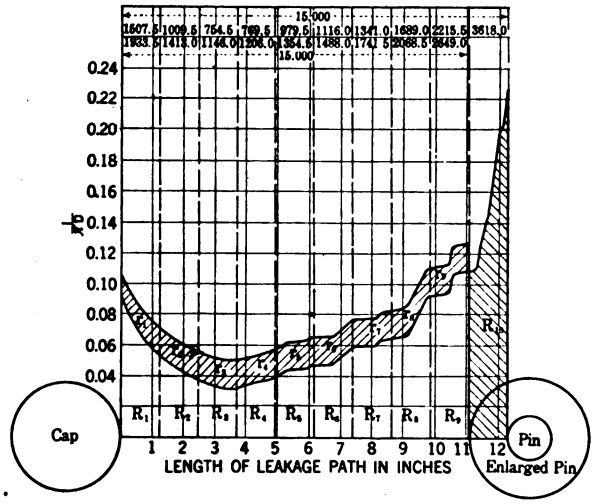

Fig. 14—Calculated Resistance Gradient and Method of Reducing Maximum Gradient

Surface resistance integral curves for Ohio Brass Co. Insulator No. 25620.
Area R_{10} = Area $r_1 + r_2 + r_3 \ldots\ldots + r_9$.
See Fig. 8 for leakage path measurements.

Under wet test the arc tends to follow along the string of insulators and the wet arc-over voltage is about 60 per cent of the dry arc-over value, or about 450,000 to 550,000 volts for 14 units, with precipitation of 0.2 in. per minute. The wet arc-over as well as the dry arc-over is affected by the string impedance and especially by the impedance of the upper two-thirds of the string.

The control of the wet arc, to keep it away from the string of insulators, is important. The following tests were made to show that the arc can be controlled in direction and kept away from the string. Fig. 24 shows the arc-over controlled so as to go to the lower crossarm. This is done by hanging two insulator units properly spaced below the line wire and then adjusting a pointer on the lower arm to direct the arc. The theory is that the units below the line will become dirty and wet and the insulation depreciate as do the line units. The adjustment for the wet and dry arc to travel to the lower arm can be very close to the arc-over for the string. Instead of hanging the

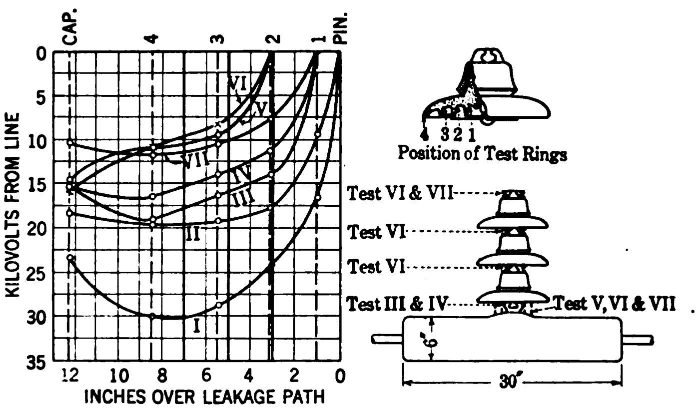

Fig. 15—Voltage Distribution over Insulator Surface

Ohio Brass Co. Insulator No. 25620.

CONDITIONS:
Voltage duty over insulator string, 127 kv. to ground. 3/4-in. iron pipe used as line conductor. Standard clamp and hardware.

TEST I:
String of 14 units of O. B. insulators. Test on bottom unit. Rings of No. 14 B. & S. copper fastened with wax in positions shown. No control shields on string.

TEST II:
String of 14 units of O. B. insulators. Test on bottom unit.
Rings of No. 14 B. & S. copper as above.
6-in. diameter iron cylinder, 30 in. long, placed over conductor and extending along conductor 15 in. each side of insulator. Ends of cylinder rounded in.

TEST III:
String of 14 units of O. B. insulators. Test on bottom unit.
Rings each replaced by two arcs of 1/4 circumference. Bisecting radius of arcs at right angles to line. 6-in. diameter cylinder as in II. Sheet iron cylinder around insulator pin between 6-in. cylinder and insulator to increase pin diameter out to position 1.

TEST IV:
Same as III, except bisecting radius of wire arcs parallel to line.

TEST V:
String of 15 units of O. B. insulators. Test on bottom unit.
Rings of No. 14 B. & S. copper fastened in positions shown. 6-in. diameter cylinder as in II. Sheet iron cylinder around insulator pin between 6-in. cylinder and insulator to increase pin diameter out to position 2.

TEST VI:
Four Hewlett insulators at top of string. Five O. B. insulators next. Four O. B. insulators with cylinder surrounding pin and in contact with cap below to give pin diameter out to position No. 1. Bottom unit as in Test V. Pin diameter to position 2 and 6-in. by 30-in. long cylinder around conductor.

TEST VII:
String of 14 O. B. insulators. Test on fourth unit from bottom. Bottom unit as in III except arcs replaced with rings of No. 14 B. & S. copper. Sheet iron cylinder surrounding pin of fourth unit and in contact with cap of third unit to give pin diameter out to position 1.

Tests by H. J. Ryan.

All tests made at Stanford University, Feb. 3, 1921.

extra units from the line wire, we may hang them from the lower arm, about two feet towards the tower from the line insulators. The wet and dry arc can by proper adjustment be made to clear the string. Instead of the insulators hung from the arm, we may hang a porcelain tube to direct the arc. The result here is even more satisfactory than for the other two cases above. Test Sheets 1 to 4 in the appendix show the result of tests of various methods of arc control.

While the wet and dry arcs may be controlled as above, it is believed this control should be used only as a final protection in certain places. *The effort should be to eliminate the arcs entirely* and it is believed this can be accomplished, except for cases of accident.

Suppression of Incipient Corona or Arcs. I am confident from all my observations and studies that the final complete success of power transmission, at voltages higher than can be handled by pin-type insulators, must come from the design of the metal fixtures (including the line wire) in contact with the air and porcelain, so that the air gradient and leakage gradient will be reduced to low values, in order that there be no tendency for arcs to start, and the maximum unit and leakage resistance will also be reduced to low values. Corona should also be prevented on account of the formation of acids.

Only a small part of the tests made have been included in this paper, in order to keep it within reasonable length. The manufacturers and engineers have heartily cooperated in the tests, and I hope to see cooperation in manufacture to bring about confidence in the transmission industry as a whole.

Conclusion

The insulator problem of the transmission line must be attacked as any other engineering problem. The attempt here made to give the results of work along this line will, it is hoped, encourage further study by engineers and manufacturers.

The insulation problem, as does every engineering problem, reduces itself to working to certain unit stresses—mechanical and electrical—and to the maintenance of certain factors of safety throughout the entire line structure, which includes insulators, towers,

switches, transformers, etc. This factor of safety should be as permanent as possible, which means that the depreciation of the insulator should be practically nil in service. This goal is being rapidly reached.

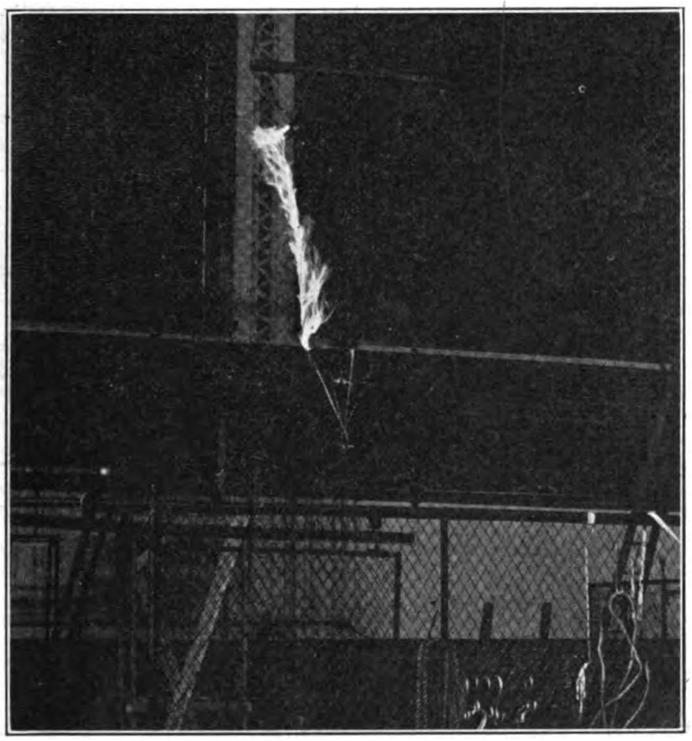

Fig. 25—Wet Arc-Over for Arrangement Shown, 508 kv. Dry Arc-Over, 728 kv.

Tests at Pittsfield, Mass.

It is shown that satisfactory voltage distribution at normal voltage may be obtained by different methods of shielding or by different methods of grading. Further work along this line is desirable in order to crystallize the best methods into practical forms, so that the insulator manufacturers will be able to furnish the complete line insulation equipment.

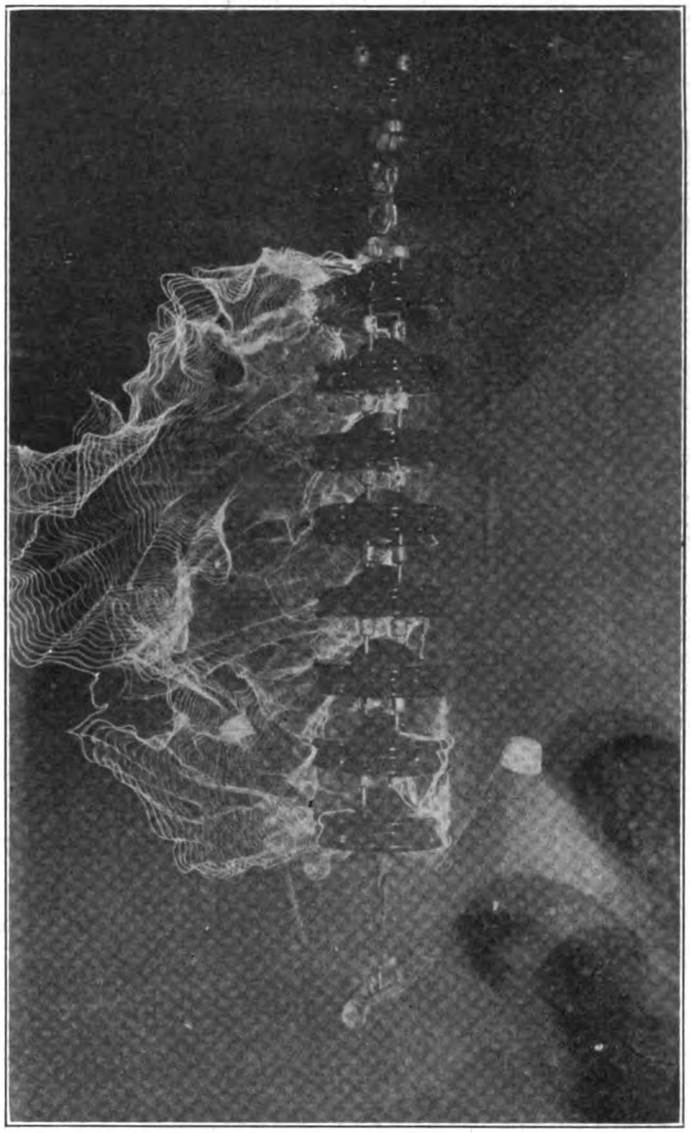

Fig. 26—Tests on No. 1054 Insulator—Without Tinfoil Caps

Wet flash-over, 331 kv.
Spacing, 5 1/2 in.
Dry flash-over for same 8 units, 380 kv.
Tests, R. Thomas & Sons.

It is believed that 220,000-volt transmission is no more difficult than 110,000 or 175,000, if due consideration is given to the unit air and leakage resistance stresses, and the insulation of the line is carried out consistently, as is, for example, the track system of our best railways. But this means, of course, that we must not have on a main-line track 120-lb. rail and 60-lb. rail over which high-speed trains run. The factor of safety in the insulated string should be at the

line wire end so that shocks may be absorbed without undue stress on these units.

Double-string and dead-end insulator strings should be avoided wherever possible, and in place of these, extra strength units should be used, to allow insulators to swing clear at angles as far as possible.

Higher voltages than 220,000 are possible, but for practical reasons, as given in Part I, it is believed

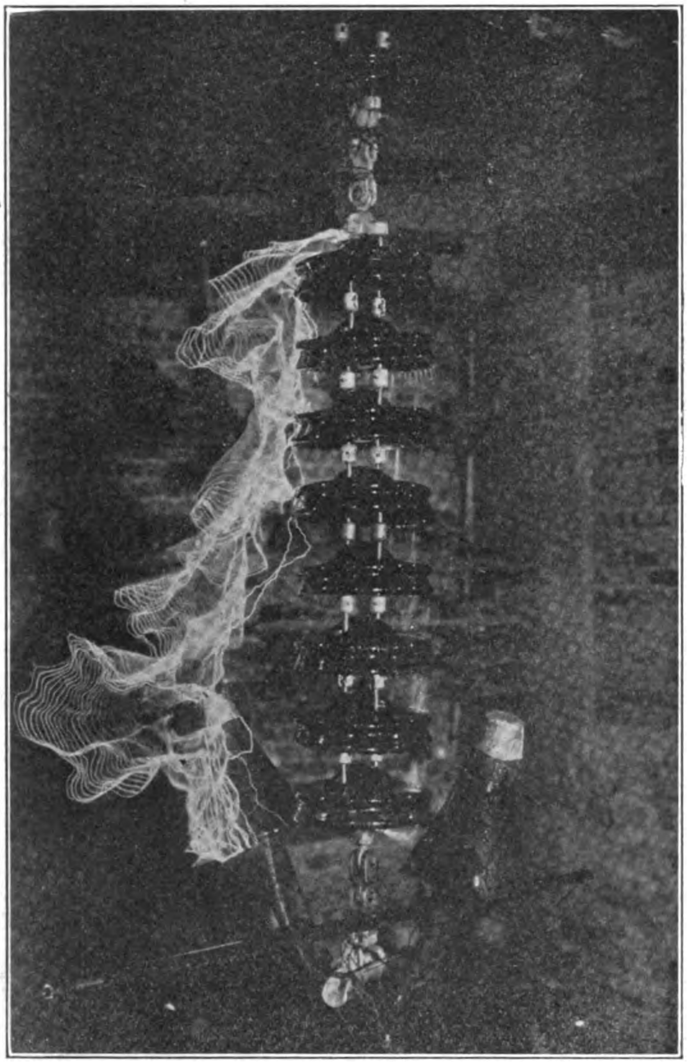

FIG. 27—TESTS ON NO. 1054 INSULATOR—TINFOIL CAPS ON HORN INSULATORS

Wet flash-over, 331 kv.
Spacing, 5 1/2 in.
Dry flash-over for same 8 units, 380 kv.
Tests, R. Thomas & Sons.

220,000 should be standard for extra large-power, long-distance transmission. Heretofore I have always said we would go to higher voltages, because we had not reached the voltage required for extra large blocks of power and long distances. I believe 220,000 volts is high enough to meet any situation in this country today.

It is the peculiar characteristic of nearly all electrical apparatus that it depreciates less when used in normal service than when taken out of service for part of each day.

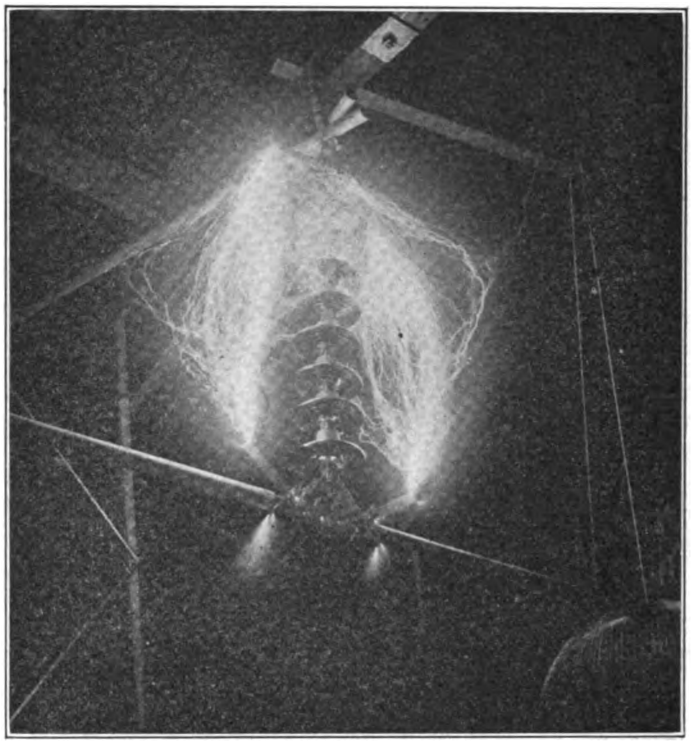

FIG. 28—NINE UNITS—30 FLASH-OVERS—10 CLEAR AND 20 CASCADE

Note bowing out of flux lines at lower end and break-down to upper part of string where string potential is low.
This figure and Fig. 29 illustrate that we must increase string potential in the upper third and decrease the air potential due to the line wire.
Figs. 28 and 29 by Prof. H. J. Ryan.

This is because the depreciation depends largely on the maximum range of temperature changes and the number of such changes or cycles in a given period. All electrical apparatus, including transmission lines,

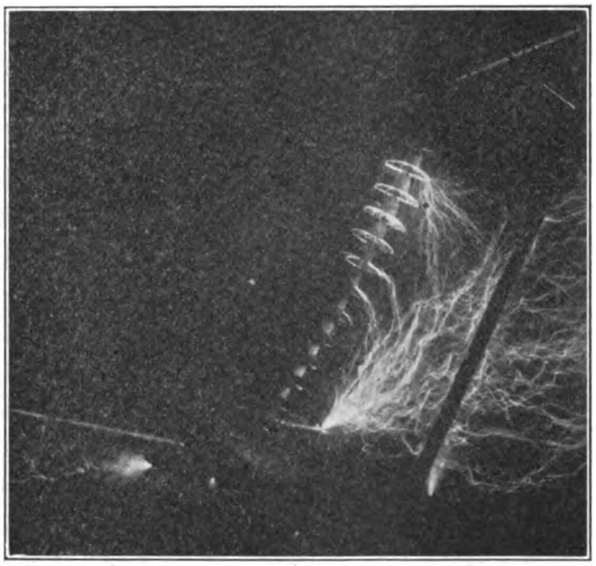

FIG. 29—TWELVE UNITS—30 FLASH-OVERS

Note bowing out of flux lines at line end due to high string potential and break-down to upper units due to high air potential and low string potential.
This figure and Fig. 28 illustrate that we must increase string potential in the upper third and decrease the air potential due to the line wire.
Figs. 28 and 29 by Prof. H. J. Ryan.

should be in constant service under conditions that will as nearly as possible cause the apparatus to remain in one condition. It is believed transmission lines will give better service when voltage is maintained on them at all times.

A system of transmission controlled as to voltage as given in Part I, and insulated consistently by one of the methods given in Part II, to give low air and resistance leakage stresses at all voltages and under all conditions, will give service not possible on lines where these conditions are not carried out. I hope to see a real era of 220,000-volt transmission construction in the next few years, and the engineers and manufacturers can help matters along by proper cooperation.

Dimensions and Output

BY LAWRENCE E. WIDMARK
Chief Engineer, Star Electric Motor Co., Newark, N. J.

The writer undertakes to demonstrate that the expression $D^2 L$ (D = Rotor diameter, L = Net iron length) as used in the electrical design does not meet modern requirements. He advocates the replacing of it by $D \times V$, where V stands for the volume of the rotor. The reasons and advantages of the new form are expounded and it is shown how a series of extremely useful relationships follow the new formula.

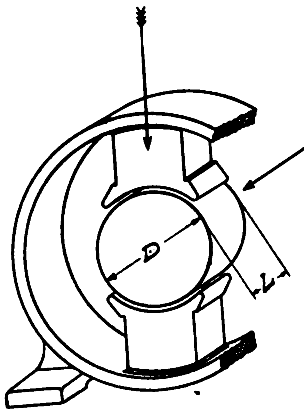
SINCE the time when the output of electrical machines was limited by the necessity of providing good heat radiating rotor surface and a low value of ampere-conductors per rotor periphery the custom has survived of calculating the electrical "capability" of a machine in reference to $D^2 L$. (D = Rotor diameter, L = Net iron length.)

Our modern way of making internally ventilated machines and the freedom with respect to ampere-conductors won by the interpoles really makes "$D^2 L$" an antiquated tool for the designer. The expression cannot be longer considered a suitable measure for the electrical sizing up of a machine.

As a matter of fact this expression takes care of three things, heat radiation, easy condition for commutation, and the magnetic flux. Only the last one is a fundamental and natural consideration. The other two vary from day to day in accordance with the prevailing trend of the current design.

Let us now try instead to find an expression that is confined to the two paramount considerations of electrical design, *viz*: the *electric flow* and the *magnetic flow*. After provision has been made in this respect it is up to us designers to arrange the dimensions so as to get the best results, but the foundation formula should be independent of our varying troubles.

The output of a machine is obviously the product of these two flows. Now what is the limiting dimension of the magnetic flux? The cylindrical area of the rotor or $\pi D L$. And what is the limiting dimension in regard to the total current volume? The armature



copper area, without doubt. This area must necessarily be limited by the total area of the slots that can be contained in the rotor disk. The conclusion is that finally the area of the rotor disk or $\frac{\pi D^2}{4}$ determines the electric flow.

In accordance with the above we shall get the expression for the possible output of the machine by multiplying the two limiting values $\pi D L$ and $\frac{\pi D^2}{4}$, and we have arrived at the solution:

That the possible output of an electrical machine should be considered as proportional to the *product of the rotor volume by the diameter thereof or* $V \times D$ and *not* proportional to $D^2 L$, or the rotor volume only.

For the practical application of this result we proceed as follows. Take the total electrical load of the rotor in watts and divide same with the rev. per min. The result we will call *watt-revolutions*. If we then have the rotor volume expressed in cubic inches we shall by dividing same by the watt-revolutions get *cubic inches per watt-revolution* which we denote by θ. Then $\theta \times D$ will turn out to be a considerably stable constant determined by three factors, *viz*:

1. The proportion of armature copper to the disk area.
2. The current density.
3. The magnetic density, total flux per square inch taken all over the rotor surface.

These three factors, of course, do not remain constant for all sizes of machines. Their general grouping, however, make the resulting constant comparatively stable. The current density is decreasing with larger machine units, while the proportion of copper section is affected in two opposing ways. When the machine size is increased the slot area compared with the disk area is likely to decrease but on account of less space required for insulation the copper per slot will increase. The variation in the magnetic condition will tend to offset the result created by the changes in the other two conditions.

The result is that the new expression gives an exceedingly good standard value for small and medium sized machines where on account of competition a standard is most necessary. For larger sized machines the constant is slowly increasing. As is well-known the old constant is no constant whatsoever for the lower end of the machine series. It is first stabilizing when it comes to larger machines.

Business consideration prevents me from discussing the numerical value of the constant, in accordance with the new expression.

A most interesting development of the expression is a study of how the different selections of the principal dimensions will affect the design of ordinary induction motors.

Starting from $V \times D = C$ or here given the form of $D^3 L = C$, we easily arrive at the following results when choosing different rotor diameters. As stator dimensions follow rotor diameter, both stator and rotor are included.

Iron length $= \frac{C}{D^3}$, inversely proportional to the cube of the diameter.

Rotor surface and total flux $= \frac{C}{D^2}$ inversely proportional to the square of the diameter.

Copper section $= C\,D^2$, proportional to the square of the diameter.

Copper volume of end connections $= C_1 D^3$, proprotional to the cube of the diameter.

Copper volume of iron length of copper $= \frac{C_2}{D}$ inversely proportional to the diameter.

Iron volume $= \frac{C_3}{D}$ inversely proportional to the diameter.

If we now try to find what selection of dimensions gives the most favorable machine we have

$$\underset{\text{(end connection copper)}}{C_1 D^3} + \underset{\text{(Copper in iron)}}{\frac{C_2}{D}} + \underset{\text{(Iron volume)}}{\frac{R\,C_3}{D}} = \text{Min.} \qquad (1)$$

C_1, C_2, and C_3 as per above, R reduces the iron volume to its copper value. For instance, copper being five times more expensive than the laminations, R equals 1/5.

Differentiating equation (1), we get

$$3\,C_1 D^2 - \frac{C_2 + R\,C_3}{D^2} = 0 \qquad (2)$$

or as we also could write it

$$C_1 D^3 = \frac{C_2 + R\,C_3}{3\,D} \qquad (3)$$

Comparing this result with equation (1) we now get the interesting fact that the cost of the active material of an induction motor reaches a minimum when *the value of the end connections equals one-third of the value of the iron and the copper embedded therein.*

Equation (3) also gives the most favorable value of the rotor diameter:

$$D = \sqrt[4]{\frac{C_2 + R\,C_3}{3\,C_1}} \qquad (4)$$

A preliminary design has for instance, given the following values:

Rotor diameter 9 in., iron length 6 3/4 in., total weight of copper 29 lb., (16 lb. for end connection and 13 lb. for copper embedded in iron). Weight of iron used for stator and rotor punchings 325 lb.

It is desired to check up the design for ratio of iron cost to copper cost of 1 to 5 and we proceed as follows:

$$C_1 D^3 = 16 \text{ lb. for } D = 9 \text{ in., } C_1 = \frac{16}{729}$$

$$\frac{C_2}{D} = 13 \text{ lb., for } D = 9 \text{ in., } C_2 = 117$$

$$\frac{C_3}{D} = 325 \text{ lb., reduced to copper } \frac{R\,C_3}{D}$$

$$= 65, \text{ for } D = 9 \text{ in., } R\,C_3 = 585$$

Using equation (4) we get $D = 10$ in.

Thus 10 in. is the proper dimension under the given cost proportion and not 9 in.

In this connection, also note that the numerical value of the diameter is very slow to change when the ratio between copper and iron cost is varied. This of course depends upon the bi-square root. Suppose for instance the ratio should be 25 per cent different. This will only affect the value of the diameter about 5 per cent.

It is also possible, however, to get a rational expression showing how the internal design of the machine affects the most favorable proportion of diameter to iron length.

Let the total copper section, (both for stator and rotor) be α per cent of the rotor disk. Let β be the proportion of the lengths of the end connections to the length of the diameter.

We will then have the following expression for the end connection copper:

$$\alpha \frac{\pi D^2}{4} \times \beta D$$

For the copper embedded in iron:

$$\alpha \frac{\pi D^2}{4} \times L$$

And for the copper value of the iron used for punching the disks:

$$R \times P^2 \times D^2 \times L$$

P stands for the proportion of stator diameter to rotor diameter and the disks are punched out of material in squares with sides equal to $P\,D$.

Using the relation for minimum cost set forth in equation (2), we get:

$$\alpha \frac{\pi D^2}{4} \beta D = \frac{1}{3} \left(\alpha \frac{\pi D^2}{4} L + R\,P^2 D^2 L \right)$$

or

$$\frac{D}{L} = \frac{\alpha + \frac{4}{\pi} R\,P^2}{3\,\alpha\,\beta}$$

As an example, we have for a certain size of machine the following values:

α = 17 per cent
β = 1 (four-pole machine)
P = 1 1/2
R = 1/5.

We then obtain for $\frac{D}{L} = 1.45$

A more or less unexpected result of above formulas is that even for four and six-pole machines, the comparatively long type seems to be by far the most favorable design and that the increase in weight of the end connections with the cube of the diameter proves to be a terrible handicap for the short, large-diameter machine.

The advantages of the suggested expression *versus* the old one may be summed up as follows:

The numerical value of the new expression starts with a final value; it is practically a "constant constant" for the commercially most important lower end of the machine series and begins to vary first with larger machines. The numerical value of the old expression starts with infinity, and is practically valueless as a guide for smaller and medium-size machines on account of its variable value

The new expression leads to a very interesting study of the most favorable design of a machine as regards cost and how the design is affected by different conditions. If the old expression is used in a similar way it will be found that the iron volume being a constant, disappears after differentiation and that therefore the cost of the iron will not be taken into consideration at all.

The new expression is easily calculated from magnetic and electric densities referring to strictly determinable surfaces of the machine, *viz.*, the rotor cylindrical surface for the flux and the disk area for the electric load; instead of referring to the comparatively indefinite induction of the air gap and the artificial and unnatural conception of current volume per rotor periphery,—or amperes per inch.

The new expression is clothed in a practical concrete and tangible form, *viz.*, cubic inch rotor volume per watt-revolution, which, multiplied by the diameter, gives a three figure numerical value, which of course is much preferable to the practical man than the form of the old expression:

$$\frac{D^2 L \times \text{rev. per min.}}{\text{Kw.}} = C\,10^5.$$

Advances in the Art of Waterwheel Designs and Settings

By W. M. WHITE

Allis-Chalmers Mfg. Co., Milwaukee

THE UTILIZATION of our natural resources for the development of power, its transmission and the employment of that power to relieve man of burdensome toil, has been an outstanding feature in the progress of Western civilization during the past half century.

The advance of communities, states and nations may be read in the record of the percentage of mechanical power utilized per man. An English statesman recently said in open Parliament meeting that the reason why American manufacturers can pay twice the wage paid the English workman and yet compete in the markets of the world, is because each American workman has behind him twice the developed horse power per man that the English workman has behind him.

Of the total power developed in the United States, that furnished by water power forms no inconsiderable part. The amount of power now developed from water is approximately nine million horse power. It has been estimated that fifty million horse power can be developed from the rivers within the borders of the United States. Of the nine million horse power, by far the major portion has been developed in the last thirty years and a curve expressing relation of time and power developed would be parabolic in form with an upward trend.

Power was first developed from water by the Chinese about two thousand years before the birth of Christ. They used paddle wheels and buckets attached to the rim of a large wheel placed in the rapidly flowing stream for the purpose of raising water for irrigation.

The early American types of waterwheels were peculiarly adapted to the locality in which they were made. From the New England States with their meandering streams and low falls came the inward flow, reaction turbine wheels, and out of the mountainous West with its precipitous streams and great falls, came the Pelton or impulse wheel.

The work of J. B. Francis of Lowell, Mass., was a notable contribution to the art, resulting in the development of the inward flow, axial discharge wheel which is essentially the present waterwheel runner of the reaction type. Splendid results were obtained by the early designers by the cut and try method. The determination of the flow of water under given conditions is difficult and is usually computed from empirical formulas founded on experimental data. The problems involved do not lend themselves to easy mathematical treatment. For example, the regulation of a hydroelectric unit with pipe lines involves the varying pressures at the wheel caused by the inertia of the water in the pipe line caused by the varying of the velocities of the water in the pipe line.

Some splendid approximate, mathematical formulas have been developed recently for determining these pressures with given pipe line conditions, but these formulas do not give exact or correct values for all conditions.

It is not difficult to set up differential equations which give proper relative values to the variables involved, but some of these equations are not soluble by the present methods available for simplifying equations.

The electrical quantities involved in the design of electrical apparatus are more readily determined than those quantities entering into hydraulic problems. The loss (friction) in an electric conductor varies directly as the current (velocity). The loss of head or friction in a pipe varies as the nth power of the velocity. The former involves equations of the first degree; the latter, equations of the second degree. The value of n is 2 for the starting of water in motion and the stopping of it; that is, v equals $\sqrt{2\,g\,h}$, and the value of n is approximately 1.85 for computing the loss by friction in pipes. $H = K\,V^{1.85}$

It is encouraging to the hydraulic engineer to know, as the writer has recently been assured, that a Professor in one of the Western colleges is now working on a table of functions somewhat similar to the logarithmic functions which will probably enable reductions of certain, now insoluble, differential equations to be made and thus enable us to make use of an exact formula in solving the problems involved in this line of work.

The energy for the production of power from water is the product of the weight of the water and the head or fall utilized. Broadly speaking, the natural configuration of the locality of the power developed, determines the head or fall available, and the drainage area and climatic conditions contributory to that locality are the principal factors in determining the quantity of water. As it seldom occurs that the configuration of the locality and the drainage area and climatic conditions are the same, so it seldom results that one hydraulic power development is an exact duplicate of the other. The hydraulic engineer, therefore, has no one fixed condition to begin with.

From the above it results that each power development requires special study to select that method and type of development suited for the particular location. The problem of finding the proper power house and dam location in the maze of contour lines calls for minute investigations and studies. It requires a great deal of time and the working out of the costs of many

Presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

preliminary studies of power house design of that particular site in order to find the proper relation of dam, pipe line, power house, tailraces, transmission lines, hydroelectric machinery, and living conditions which will result in the most economical and satisfactory development. The advance of the art must be taken into consideration because what treatment was satisfactory for a given development even five years ago can now be improved by making use of recent advances in the art of waterwheel design and settings.

The modern trend is to develop completely any given power site. The number of units in the given plant is dependent upon the service to be rendered by the given plant. The network of transmission lines is now becoming so extensive that isolated power plants are the exception rather than the rule, as formerly. In an isolated power plant it was necessary to divide the development into several units, usually at least four, so that continuity of service could be maintained by allowance for repairs and renewals. Most of the isolated early developments have now grown to huge dimensions having many plants interconnected with themselves and, in many cases, interconnected with adjacent companies, and now many companies have lines of interconnection reaching into several states. The hydroelectric station in the large systems today is the unit just as the individual waterwheel and generator were the individual unit years ago. The engineer is at liberty, therefore, to handle this unit in any manner which will make for economy in construction, efficiency in operation, and reliability of service. All three of these considerations really demand the same thing—the largest single unit which can be installed in the particular development under consideration, thus doing away with several small units with an additional spare unit.

Speed

Having determined upon the size of unit for a particular setting, the speed of the unit is practically fixed for that head. A formula which has been used for sometime as fixing the upper limits of speed is as follows:

$$\text{rev. per min.} = \frac{\left(\dfrac{5050}{H+32} + 19\right) H^{5/4}}{\sqrt{\text{h. p.}}} \qquad (1)$$

Where

H equals head acting on the turbine

h. p. equals the maximum horse power of the turbine.

The formula (1) applies to a single runner and, in the case of multirunner units, the maximum horse power of the unit is to be divided by the number of runners and the horse power per runner substituted in the formula (1).

The maximum horse power of the turbine is usually from 15 to 25 per cent more than the actual power required to drive the combined unit at its best efficiency. This relation results from the fact that the maximum efficiency of a waterwheel occurs at from 0.8 to 0.9 load, depending upon the type of runner used and the desire to have overload capacity on the turbine. The rev. per min. given by the formula (1) is altered to conform to synchronous speed. The above formula is not rigidly adhered to, although it has been arrived at by incorporating in its factors the experience of all of the waterwheel builders for many years past. Each manufacturer has a line of developed waterwheel runners and is frequently in position to make a selection of speed which will result in considerably lower cost to the customer because of developed apparatus, and in all cases a reliable waterwheel builder should be consulted as to speed. The matter of the selection of speed will be again referred to under the subject of "Specific Speed."

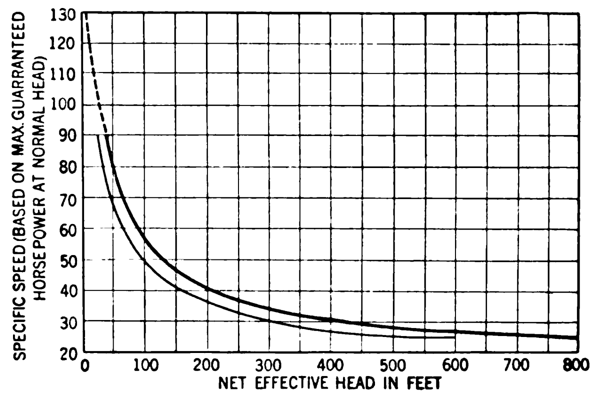

FIG. 1—SPECIFIC SPEED LIMIT CHART

FORMULA

$$N_s = \frac{5050}{H+32} + 19 \text{ in ft.} = \text{ft-lb. lb. units}$$

$$N_{s_m} = \frac{22{,}500}{H+32} + 84 \text{ in metric units} = 4.45\, N_s$$

Insert H in feet in both formulas.

Specific Speed

Specific speed is the speed at best efficiency which a given runner will make when reduced homologously to such size that it will produce one horse power under one foot head. The value of the specific speed of a given runner fixes definitely that runner as a type with relation to all other runners. The formula for specific speed is as follows:

$$N_s = \text{rev. per min.} \frac{\sqrt{\text{h.p.}}}{H^{5/4}} \qquad (2)$$

For simplicity of computation in common practise, the horse power of the turbine is reduced to h. p_1. That is, the horse power which that particular unit would give under one foot head. This is obtained by dividing the horse power by the three halves power of the head.

The rev. per min. is reduced to the number of revolutions that particular turbine would give under one foot head, or, namely, rev. per min_1. This is obtained by dividing the rev. per min. of the given

turbine by the square root of the head; therefore, formula (2) becomes:

$$N_s = \text{rev. per min.} \sqrt{\text{h. p.}} \qquad (3)$$

The curve shown in Fig. 1 expressing relation of specific speed and head was determined by plotting the specific speeds of practically all of the noted plants in the United States and some abroad with relation to the head under which they were operating, noting on the point so plotted those plants on which no pitting occurred and those on which pitting of the runner did occur, or noting any other unstable or unsatisfactory performances of plants in operation. A curve was then drawn below the points representing plants on which pitting occurred or which were unsatisfactory on an average, and above the points representing all of the plants on which pitting did not occur and which were satisfactory and efficient in operation. A curve

$$Y = \frac{5050}{H + 32} + 19 \qquad (4)$$

plotted with vertical ordinate as specific speed and horizontal ordinate as head gives the specific speed curve referred to above and is the factor used in the derivation in the original equation (1). Steady advances are being made and no doubt speeds higher than those indicated in formula (1) will ultimately be adopted. There is probably no other thing in the design of a hydroelectric plant that received more discussion than the question of the speed of the units. There are several contending forces: The electrical engineer desires usually the higher speeds in order to cheapen the cost and frequently increase the efficiency of the generator. On the other hand, the waterwheel designer prefers his lower speed usually for better efficiency throughout and, certainly, for higher efficiency at lower or part gate loads, and for freedom from troubles in the field such as pitting, erosion and vibration.

It does not always follow that the speed as given by formula (1) does result in a satisfactory waterwheel unit, but the most skilled designers are now enabled to produce those speeds and sometimes higher without dangerous pitting or cutting.

The size of waterwheel units has steadily increased to such a point that now the cost of the generators does not vary as widely with the change in speed, so that it may result that, in the design of larger units now in general contemplation, this troublesome case may settle itself.

Speed Regulation

The great inertia of the moving mass of water to and from the waterwheel produces difficulties in the regulation of the speed of the waterwheel unit which can best be controlled by making use of the inertia of the revolving parts of the waterwheel and generator. The greater the inertia of the enclosed supply water, the greater the $W R^2$ necessary to give good regulation. The factors entering into the control of the speed are:

(a) the time (t) in which the water is shut off from or turned on the unit.

(b) the increase or decrease of the effective head on the turbine occasioned by such change.

(c) the inertia of the revolving mass which resists change of speed by acting as a reservoir for the energy unabsorbed otherwise.

The governing apparatus is frequently unfairly charged with poor regulation, when all that apparatus can do is to open or close the turbine gates within a predetermined time (t) when actuated by a change in speed. The formula most commonly used for quick computation of speed change, although not exactly correct, gives results well within the limits required.

$$\Delta = \frac{800{,}000 \times \text{h. p.} \times t}{\text{rev. per min.}^2 \times W R^2} \qquad (5)$$

Where

Δ is the ratio of increase or decrease in speed

h. p. is the horse power suddenly thrown on or off

t is the time for the movement of the gates of the turbine

$W R$ equals the inertia of the rotating parts of the waterwheel and generator.

Formula (5) is used only for open flume turbines or where the change in pressure or head resulting from the change in flow, is too small to be considered. For cases where load off results in an increase of head at the turbine inlet, the following formula may be used with good results:

$$\Delta = \frac{800{,}000 \times \text{h. p.} \times t}{\text{rev. per min.}^2 + W R^2} \left(1 + \frac{\Delta H}{H}\right)^{3/2} \qquad (6)$$

In case of load suddenly thrown on, the formula becomes:

$$\Delta = \frac{800{,}000 \times \text{h. p.} \times t}{\text{rev. per min.}^2 \times W R^2 \left(1 - \frac{\Delta H}{H}\right)^{3/2}} \qquad (7)$$

Where

H equals effective head, feet

ΔH equals change in head, feet

For a more thorough discussion of speed regulation the reader is referred to Mr. Arnold Pfau's paper, "The Speed and Pressure Regulation of Hydraulic Turbines," copies of which the author will be pleased to furnish.

The resulting change of effective head operating on the turbine caused by the movement of the gates within the time (t) is dependent upon the velocity and length of the column of water. Manifestly open flume turbines are easiest of all to regulate. Turbines having long pipe lines with high velocities cause greatest difficulties in regulation. Modern governors are equipped so that they may be readily adjusted for moving the gates open or closed in a predetermined time, usually a different time for closing and opening

the gates in order to avoid synchronous waves in the pipe line. An important factor to be taken into consideration is the fact that the horse power to be inserted in formula (5) is the change in horse power which is developed under the changed effective head acting on the turbine, due to the change in pressure occasioned by the quick movement of the gates. Reference was made at the beginning of the paper to the complicated mathematical solution of the problem of regulation, but a fair understanding of pressure changes at the turbines may be had from the following formula.

$$H = \frac{L\,V}{G\,t} \tag{8}$$

H equals the increase or decrease in head
L equals the length of the water column in feet including draft tube
V equals the change in the average velocity of the water in feet per second within the time (t)
G equals the value of force of acceleration of gravity equals 32.2 ft. per sec. per sec.
t equals the time in seconds in which the change in velocity is made.

There are many factors which enter into the exact mathematical solution such as the elasticity of the pipe line, the ratio of change in velocity for any small increment of time during the time (t) and the ratio of the increase or decrease of the pressure for any small increment of time during the time (t). There are certain peculiar conditions for length of pipe line, velocity in the pipeline and time of movement of the turbine gates which will result in an actual increase of power on the turbine as the gates are closed. In other words, the increment of increase of head is greater than the decrement of the decrease in quantity. The length of the pipe line is fixed by the natural conditions surrounding the development, but the velocities within the pipe line can be controlled and predetermined by the selection of the proper size of pipe line. The cost of the increase in the diameter of the pipe line may be excessive and it frequently results that $W R^2$ may be secured in the generator or in a flywheel at much less cost. If the pipe line conditions are rather rigid and fixed, it becomes necessary to provide proper $W R^2$ to secure the desired regulation as may be computed from formulas (6) and (7). The regulation constant has been determined by observing in power plant operation the $W R^2$ and other conditions necessary for reasonable regulation. The constant is set up by the following equation:

$$K = \frac{(\text{rev. per min.})^2 \times W R^2}{\text{h. p.}} \tag{9}$$

It will be noted that the constant K includes three of the principal factors of equations (5) (6) and (7).

The value of K should not be less than four million for open flume construction and runs as high as fifteen million on some of the successfully regulated plants having long penstocks with reasonably high velocity.

As waterwheel runners have a very small $W R^2$ compared with that of the generators which they drive, the generator should have a constant for regulation of not less than four million as stated above.

Pressure regulators are used in connection with the governors to reduce the rise of pressure on closing of the gates. They are expensive, however, and where it is possible to obtain substantially equal regulation by increasing the $W R^2$ and omitting the pressure regulators, with consequently slower governor operating time at anything like the same cost, it is preferable.

Runner

The most important single piece in the make-up of the water wheel is certainly the runner. The function of all the headworks, supply lines, casings, speed rings, and guide vanes, is to deliver to the runner the maximum amount of energy with proper relation of velocities and pressure, and the function of the proper draft tube or regaining devices beyond the wheel is to return to the runner in the form of added head, as hereafter explained, the maximum amount of energy. The function of the runner, therefore, is to transform the maximum amount of energy delivered to it into mechanical power on the waterwheel shaft.

The diameter of the runner is fixed by the relation

$$\pi D N = \phi \sqrt{2 g H}$$

Where
D = diameter of runner in feet.
N = rev. per min. ÷ 60.
ϕ = coefficient.
H ÷ the effective head on the turbine as measured from the equivalent pressure head at the entrance to the casing plus the distance from the point of measurement to the level of the tailwater in the tailrace.

The value of ϕ varies from, say, 0.6 for very high-head wheels to, say, 0.8 for low-head wheels. The diameter (D) is the diameter of the circle touching the intake edges of the runner vanes along the center plane of the guide casing.

For purpose of explanation let us consider a runner of normal specific speed, say 35, (shown in Fig. 3) where ϕ would equal 0.72, and where the water delivered from the guide vanes to the runner would have its energy about equally divided into velocity and pressure. The runner, therefore, receives the water in a whirling vortex, yet under a pressure of about one-half of the head, and the shapes of the runner vanes are formed so that the water in passing through the runner is directed backward to the rotation of the runner and is discharged from between the runner vanes at a velocity substantially equal to the forward velocity of the runner, so that theoretically and ideally the water should flow parallel to the shaft into the draft tube with a minimum loss, considering the di-

ameter of the discharge of the runner band and the necessary velocity at that point to pass the quantity of water required. This condition of axial discharge is not attained and as a matter of fact is not desired for maximum efficiency. Pitot tube traverses made across the draft tube near the runner band show that usually the water at best efficiency whirls with the runner near the outer band and against the rotation of the runner near the inner band. The amount of energy discharged from the runner, therefore, is greater than that given by

$$\frac{V^2}{2G}$$

where V is the average velocity of the water flowing axially through the upper end of the draft tube where it joins the runner.

The number of vanes or buckets in the runner varies from thirteen to twenty-four depending upon the specific speed of the runner and the head under which it operates. The condition to be satisfied in the selection of the number of vanes is that number which will form passages through the runner sufficiently smooth in shape to avoid eddies and cross currents, and yet not too many vanes as contrasted to the friction which is introduced by the accumulated surface of too many vanes. The diameter of the runner at discharge is contracted until a balance is arrived at between the loss due to the velocity discharged from the runner and the friction loss saved by reduction of vane surface.

Another factor entering into the number of vanes is the question of pitting or erosion. Too few vanes will not give a proper channel between the vanes which results in the water leaving the back side of the vanes near the outer band creating a vacuum and slapping, action causing mechanical erosion, or creating a vacuum in which collects nascent oxygen which eats away the vanes, or a sudden release of air from the water setting up currents causing electrolysis. All or any of the above reasons may be the real one; you may take your choice. The higher the specific speed the greater the ratio of the diameter of discharge of the runner to the nominal diameter D of the runner. If the specific speed is increased the discharge band of the runner is gradually enlarged with respect to the nominal diameter and runners of 100 specific speed have a diameter of the discharge of the runner of 1.3 times the nominal diameter.

As the specific speed is increased the question of friction becomes the controlling element, consequently, this results in a reduction of the number of vanes, and a reduction of the size of the outer band which at maximum specific speed leads to the Nagler runner wherein the outer band is eliminated and the number of vanes reduced to a minimum. Three vanes in this type of runner have been found to give good results.

The problem of determining mathematically the results of flow in a straight pipe are so difficult, as set forth at the beginning of the paper, that it is apparent that any mathematical formula attempting to predict the results of a given runner under a given condition involving as it does not only friction losses to the 1.85 power but also centrifugal force, shock losses, disk friction losses and reaction losses, certainly has no place in this paper. The reader will be interested, we hope, in a statement of the various types of runners. Probably no single part of any apparatus has been fixed more by cut and try, and experimental methods than the runner of a waterwheel.

Fig. 2 is a runner having a specific speed of 21.5 designed to operate under a head of 415 ft. Fig. 3 is a runner of 34 specific speed designed to operate under a head of 215 ft. Fig. 4 is a runner of 67.7

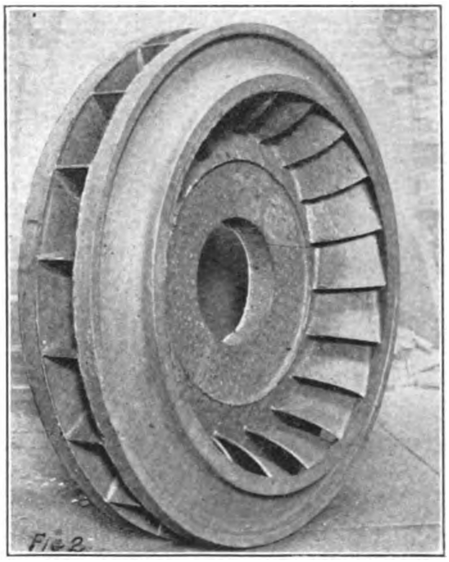

Fig. 2—55-in. Runner

specific speed designed to operate under a head of 68 ft. Fig. 5 is type No. 13 with a specific speed of 94 designed to operate under heads below 30 ft. Fig. 6 shows a four-bladed Nagler wheel having a specific speed of 137.

Runner Material

The runner being subject to greater stresses and greater wear, due to high velocities, than any other part of the waterwheel should have wearing rings and wearing surfaces wherever possible to facilitate ease of repair.

The ideal runner material is bronze and preferably without any zinc. A composition which has been found eminently satisfactory for this purpose is composed of 90 parts copper, 10 parts tin with a trace of phosphorous. It is economical to use bronze runners on high-head units providing the bronze runner is not too heavy in weight resulting in an excessively expensive runner. Cast steel runners have been used with ex-

cellent results on high-head and intermediate-head units. Cast steel is desirable on high-head large runners where the weight of the runner is heavy. Cast iron runners have been used with success on the highest

FIG. 3—SHOP VIEW OF 125-IN. CAST IRON RUNNER FOR THE LARGEST COMBINED HYDROELECTRIC UNIT IN THE WORLD

head turbines although they are not as satisfactory as the steel, because at these high heads the velocity of any foreign material flowing through the guide vanes

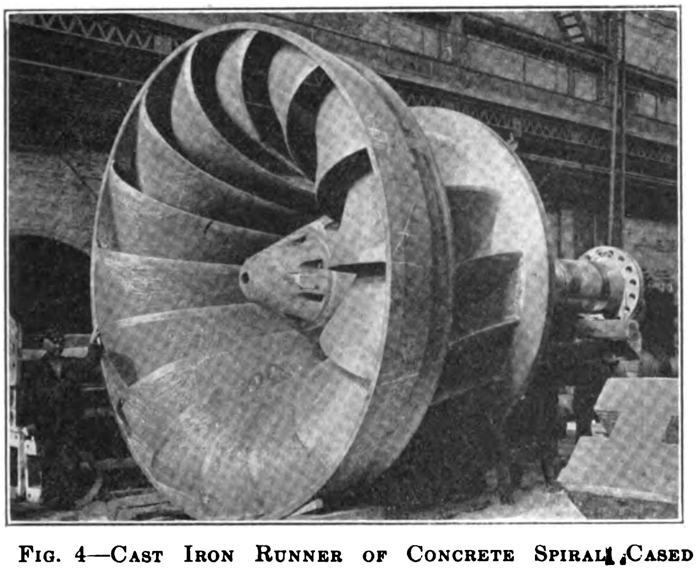

FIG. 4—CAST IRON RUNNER OF CONCRETE SPIRAL CASED TURBINES

35-ft. head, 90-rev. per min.

is so great as to break out portions of the cast iron. Cast iron runners are entirely satisfactory for all heads, say from 200 ft. downward.

A type of runner which has been used with considerable success for intermediate and low heads, is one in which the vanes are made of plate steel pressed from forms and then cast integral with cast iron crowns and cast iron outer bands. These runners have the advantage of having very smooth surfaces resulting in

less skin friction, and also have the added advantage that the runner vanes may be bent back into position after having once been broken by foreign material entering the runner, which does happen from time to time. Fig. 7 shows a good example of this type of

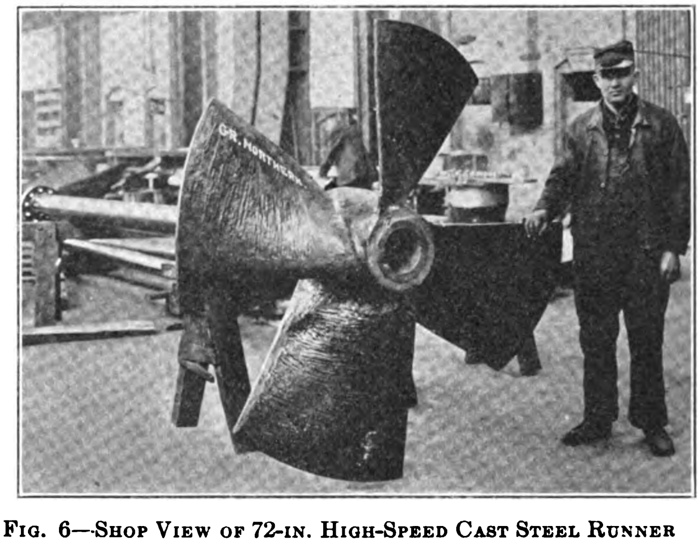

FIG. 6—SHOP VIEW OF 72-IN. HIGH-SPEED CAST STEEL RUNNER

runner in which the vanes are made of plate steel ⅝ in. thick. Their specific speed is 102.5. These turbines are operating under 18.5 ft. head at 136.6 rev. per min., developing over 825 horse power.

The propeller type of wheel as described in Mr. Nagler's paper, Vol. 41, No. 12, A. S. M. E. *Journal*, entitled, "A New Type of Hydraulic Turbine Runner," has been in use with cast steel vanes cast solid with the hub. Another type in use is cast iron. Another interesting type is that in which the vanes are formed of plate steel and are cast integral with the hub.

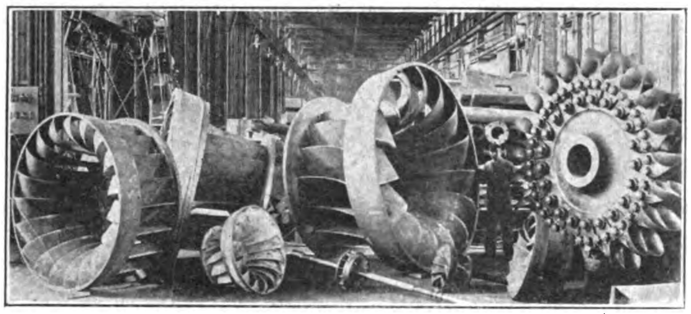

Fig. 7—Various Sizes and Types of Allis-Chalmers Waterwheels

For heads varying from 8 ft. to 2000 ft.
The two large runners in the center have plate steel vanes, as well as the small one just below the impulse wheel.

Draft Tubes

The twofold function of the draft tube is not usually understood. Its function is, first—to enclose and seal a passageway from the runner to a point below the surface of the tailwater so as to produce a suction action at the discharge from the runner, at least equivalent to the difference of elevation between the runner

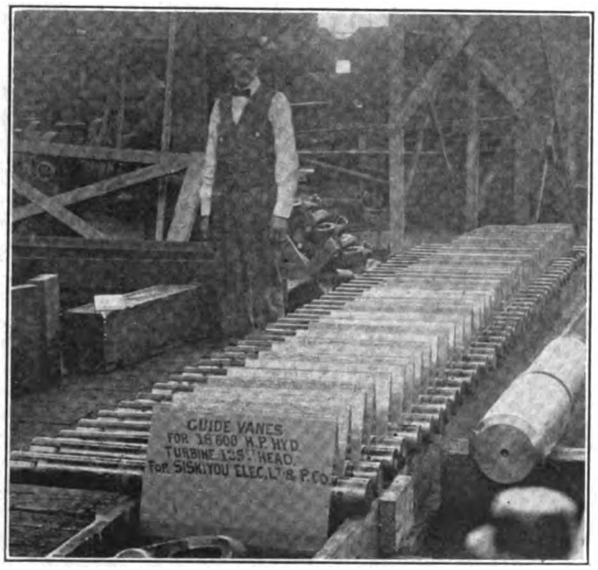

Fig. 8—Guide Vanes for Twin Horizontal Cylinder Steel Plate Casing Hydraulic Turbine

Two units, 125-ft. head, 18,600-h. p., 200-rev. per min.

and the level of the surface of the tailwater. Second—to transform the energy in the form of velocity head discharged from the runner into energy in the form of pressure head. This action may be a little more clearly understood by imagining a horizontal flow in which the flow at a given point is at a velocity equal to that being discharged from the runner, and further down stream where the cross-section is increased and the velocity slowed down, the elevation of the water will be found to be higher than at the upper point. The

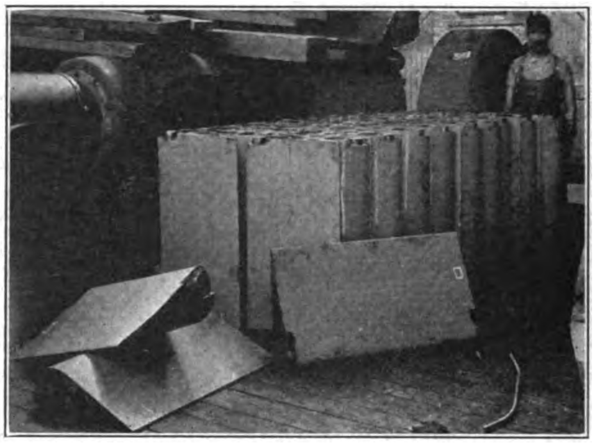

Fig. 9—Guide Vanes for Twin Vertical Open-Flume Hydraulic Turbine

Four units each 4,675-h. p., 30-ft. head, 100-rev. per min.

amount of this height is dependent upon the efficiency with which the conversion of velocity into pressure takes place. Therefore, the second function of the

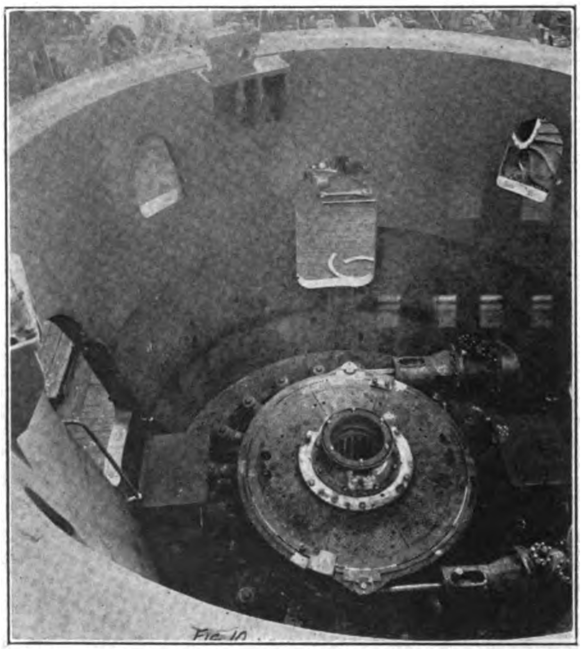

Fig. 10—Inside View of Single Vertical Turbine with Steel Plate Spiral Casing and Cast Iron Supporting Barrel for Generator

8,500-h. p., 53-ft. head, 100-rev. per min.

draft tube is to transform that velocity head into pressure head, thus creating an added suction at the discharge of the runner equal in amount to the velocity head times the efficiency of conversion. This amount added to the difference of elevation between the bottom

of the runner and the level of the tailwater gives the total added suction at the runner. By this conversion of velocity back into pressure and by this greater suction action being maintained at the discharge of the runner, the effective head on the waterwheel and runner up to the point of the discharge from the runner is greater than the head as measured from the equivalent level back of the waterwheel to the elevation of the

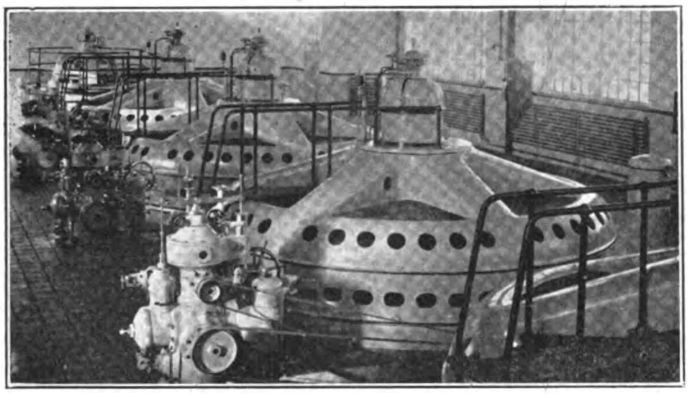

Fig. 11—Five Vertical A-C. Generators—Thrust Bearings Carried on Upper Housings

Direct-connected to 560-h. p., open-flume turbines with self-contained governors.

tailwater. Therefore, by the conversion of the velocity head into pressure head by means of some proper form of regainer and maintaining a greater suction at the runner by means of this discharged energy, the discharged energy is thus used by the waterwheel runner for the production of effective power.

A complete vacuum will cause the water to rise within it to about 34 ft. above the level of the outside water depending upon the air pressure at that particular locality and time. The height, therefore, to which a runner may be located above tailwater level is limited. We turn again to past experience for the factor fixing that height. It has been found that a runner of moderate specific speed may be placed so that the maximum suction at the base of the runner does not exceed 27 ft. theoretically. In determining the theoretical suction there is added to the elevation of the runner above tailwater the total velocity head in the water discharged from the runner, that is, to say, the efficiency of conversion is assumed to be 100 per cent. This is the limit of good practise, and where possible, other things being equal, this should be kept lower. As pointed out previously there is a limit to which the topmost point of the runner at its discharge can be placed. When large runners are placed with shafts in horizontal position the center line of the shaft is necessarily kept low with relation to the tailwater elevation in order to keep the top of the runner at discharge within the limits as set forth. This elevation of the shaft frequently depresses the generator into the foundations below the level of high tailwater and sometimes of even normal or low tailwater. This is a good reason for the adoption of the vertical shaft. An interesting setting is that of the Kerckhoff Station of the San Joaquin Light & Power Corporation where the turbine pit is excavated from granite and draft tubes driven from the bottom of the excavation out to the river channel as illustrated in Fig. 21. This design enabled the avoidance of cofferdams which would have been very expensive at this location.

The regain of energy from the velocity discharged from the runner may be accomplished more or less effectively by—

(a) straight conical tubes.
(b) curved draft tubes.
(c) hydraucone regainers.

Straight conical tubes will regain the energy with high efficiency provided the space available within the power house foundations is sufficiently ample to permit the installation of a long conical tube having a length of preferably more than four times the diameter of the draft tube where it joins the runner. Most of the curved draft tubes are a delusion and a snare. Recent investigations along these lines have shown that curved tubes now in use are so poor in regaining efficiency as to seriously detract from the power plant efficiency.

The Hydraucone Regainer is a new device for regaining pressure from velocity within the limited space available within the power house foundations. It contemplates spreading out the flow of the water on some

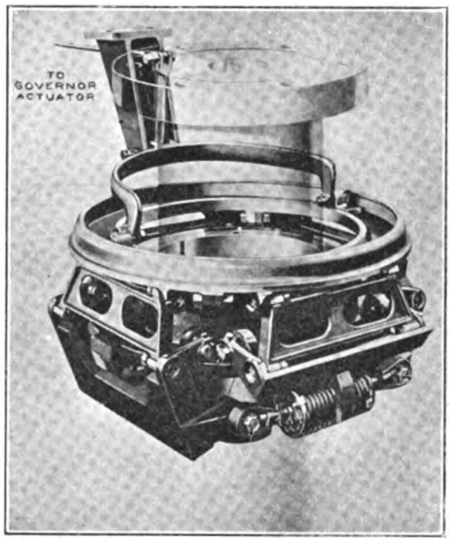

Fig. 12—Direct-Connected Flyball Governor

For mounting on the main shaft.

form of either flat or conical plate and then placing around the surface of the stream an envelope of gradually increasing greater capacity over that required to just enclose the free shape. In the case of the proper conical center a gradually enlarging capacity may be obtained wherein the pressure from velocity is regained. The conical center is not essential as tests have proved that substantially the same results have been secured

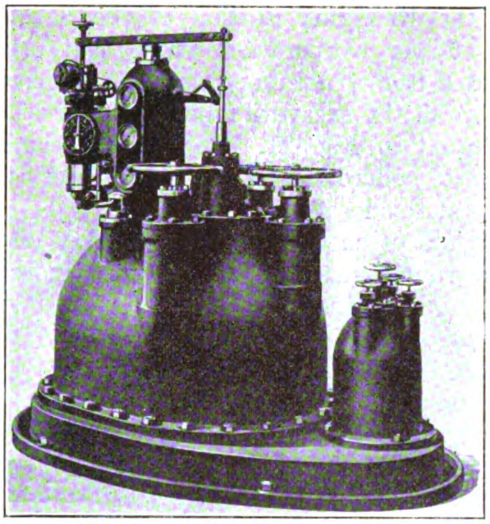

FIG. 13—SPECIAL CENTRIFUGAL CONTROL STAND FOR TYPE NO. 4 ALLIS-CHALMERS HYDRAULIC TURBINE OIL PRESSURE GOVERNOR USED IN CONNECTION WITH FLYBALLS MOUNTED ON THE TURBINE MAIN SHAFT BELOW THE GENERATOR

Vertical unit 37,500-h. p., 214-ft. head, 150-rev. per min.

by the omission of the conical center even in regainers having the upper walls especially designed with reference to the cone center. This result, however, may be accomplished only when a conoidal chamber does not vary too widely from the hydraucone which would be formed upon the particular base used. The outwardly extending passages in this form of regainer increase the efficiency of the waterwheel at full and particularly at part loads, since the centrifugal force of the whirling water may be effectively utilized in these outwardly extending passages.

A summary of the experiments conducted in perfecting the Hydraucone may be found in the paper, "The Hydraucone Regainer, its Development and Application in Hydroelectric Plants," which was read by the writer before the Spring 1921 Meeting of the American Society of Mechanical Engineers.

The curved draft tube is illustrated in Fig. 17. The Hydraucone Regainer is illustrated in Fig. 14. The Hydraucone Regainer has an efficiency of conversion of between 70 per cent and 80 per cent depending upon the available width between the walls of the power house foundations.

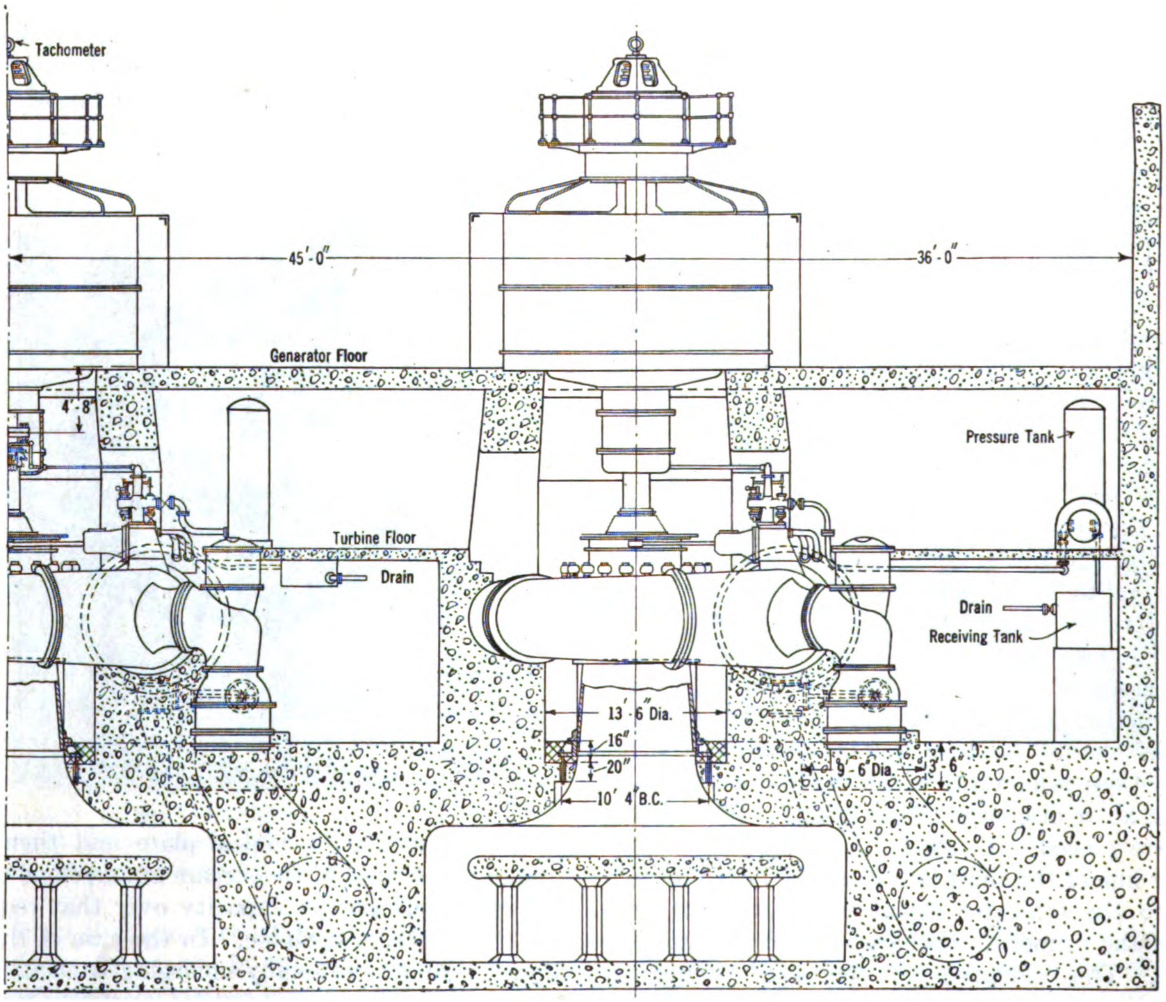

FIG. 14—VIEW OF 40,000-H. P. 421.5-FT. HEAD, 257-REV. PER MIN. TURBINES

Shaft and Bearings

The main shaft is usually tapered and fitted into the hub of the runner. The shaft is sometimes made with a forged sleeve at the runner end to which the runner is secured by means of bolts. The former is

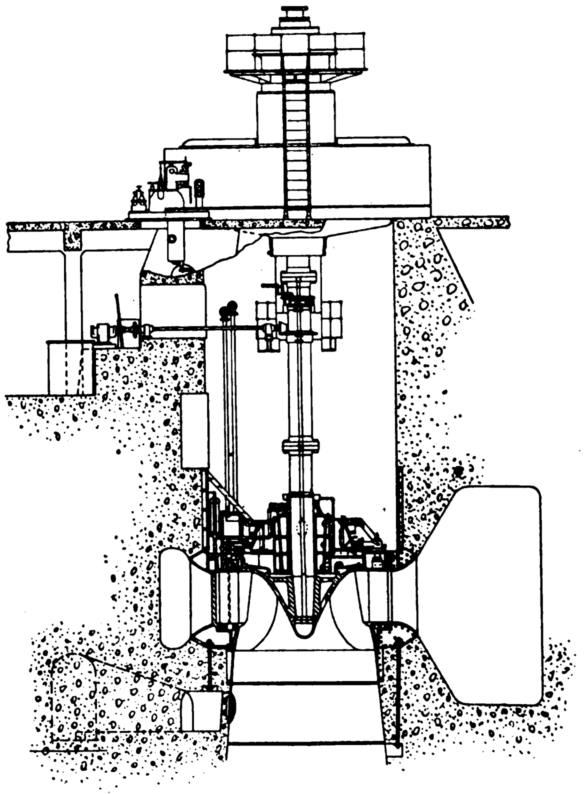

Fig. 15—Showing Oil Pump Gear-Driven from Main Turbine Shaft

Wateree Power Co.

the preferred method of fastening the runner when lignum vitae bearings are used on the waterwheel, because by its use a renewable sleeve may be most cheaply and effectively applied to the shaft on which the bearing surfaces are caused to bear. It was formerly the practise to make these renewable sleeves on the shaft of bronze, but later tests have shown that rings forged from alloy steel provide surfaces of greater hardness and longer wear at no greater expense. It may be argued that the steel will rust, but the modern hydroelectric units are so well and strongly designed that they are seldom out of use, therefore, the question of rusting of the shaft is not a factor in arriving at the proper decision. Lignum vitae bearings have been used as illustrated in Fig. 18 for many years with good success. Where the speed is not too high and the generator is located immediately above the waterwheel, the lower generator bearings may be omitted and the one waterwheel bearing may serve as the lower guide bearing of the generator as well as the guide bearing of the waterwheel. An interesting installation embodying this feature of design is that of the Cheoah Plant of the Aluminum Company of America, equipped with Allis-Chalmers generators and Allis-Chalmers waterwheels, and lignum vitae lower bearing. This plant contains three 27,000-h. p. waterwheels operating under a head of 180 ft. Another interesting plant is that of the Tallassee Power Company at Badin, N. C., where an oil bearing is substituted for the waterwheel guide bearing and this oil bearing serves for the lower generator bearing as well as the waterwheel guide bearing. Wherever it is at all possible the waterwheel and generator shaft should be reamed together in the shops of the makers of one of the shafts, the bolts fitted to the shaft and the whole shaft turned in a lathe to be sure that the shaft turns true, before shipment. Open-hearth steel forgings of the simplest composition make the best waterwheel shafts because the problem involved is of stiffness rather than strength. It is most interesting to note

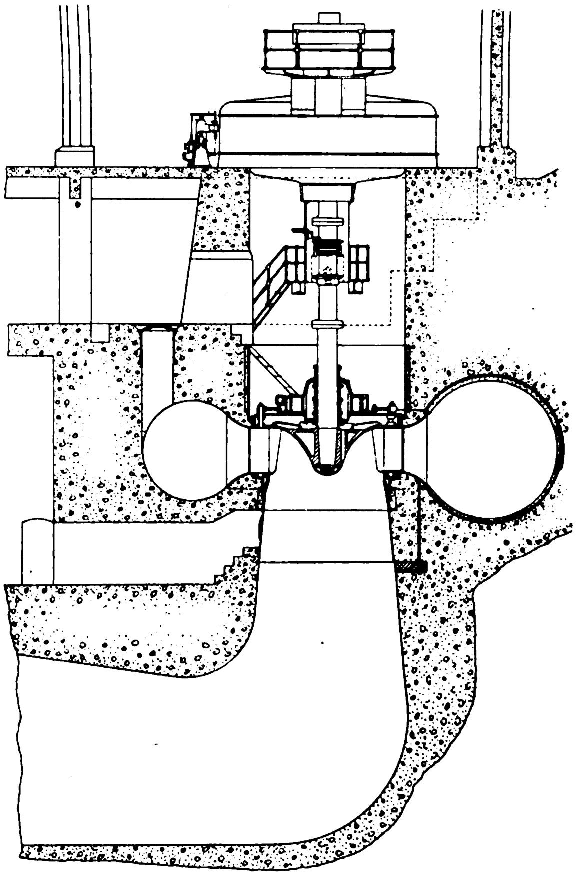

Fig. 16—Cross-Section of Spiral Casing Formed in the Concrete with Reinforcing Bars Attached to the Speed Ring Flanges

15,000-h. p., 68.5-ft. head, 112.5-rev. per min.

that recent experiments are proving the superiority of the open-hearth steel shaft as against the specially compounded alloy materials.

Guide Vanes

The trend of modern designs is strongly toward the cast steel guide vane having stems cast integral

and controlled by levers and operating mechanism placed outside of the water. Fig. 8 shows some of the guide vanes for the Siskiyou Electric Light & Power Company, 18,000 h. p., 125 ft.

The number of guide vanes is fixed with the same considerations as that fixing the runner vanes, that is, adopting only sufficient guide vanes to 'orm smooth

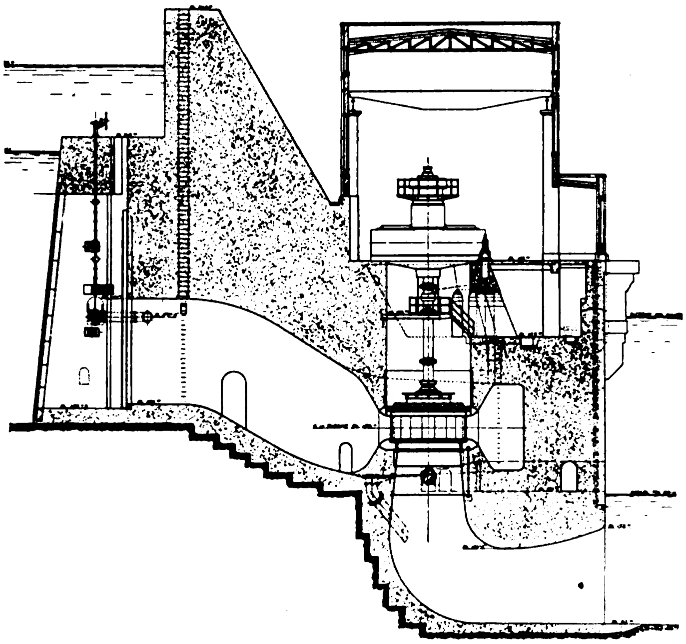

Fig. 17—One of Five Complete Allis-Chalmers Hydroelectric Units
Each 20,000-h. p. under 75-ft. head at 100-rev. per min.

passages so that the water will be delivered to the runner in as nearly one uniform whirling rotation as possible without too many guide vanes so as to avoid the too great accumulated vane surface resulting in friction losses. The favored number of guide vanes of this type seems to be twenty. The shape of the guide vane is that left to the individual designer. The writer has used the design of vane illustrated here many years with good success. The guide vanes are controlled by links and levers to one common shifting ring. It is essential that some adjusting device be interposed between each vane and shifting ring whereby the vanes may be adjusted so as to prevent excessive leakage in the closed position. The adjustable feature is particularly useful when the vanes are sprung due to obstructions lodging between two vanes when closing the unit down. Breaking links interposed between each guide vane and the shifting ring are essential, and that type of link should be used which may be readily replaced without unwatering the turbine.

Cast iron guide vanes, bronze bushed, such as shown in Fig. 9, connected by links to a shifting ring make a very satisfactory arrangement for open flume settings. An adjusting means should be inserted between each guide vane and shifting ring as in the former case.

A recent invention of plate steel guide vanes formed from one sheet of metal welded along one edge, has the advantage of having an unusually smooth surface, and of being easily repaired when distorted by foreign substances entering the wheel. It is particularly useful in low-head installations. The ideal control of the guide vanes and operating mechanism is that illustrated in Fig. 10, wherein the operating cylinders are fixed to the pit ring and operate directly through reach rods to the shifting ring. A very satisfactory arrangement is that wherein the operating cylinder is located on the main generator floor exerting its effort through a vertical shaft to cranks and levers connection to the shifting ring as shown in Fig. 11.

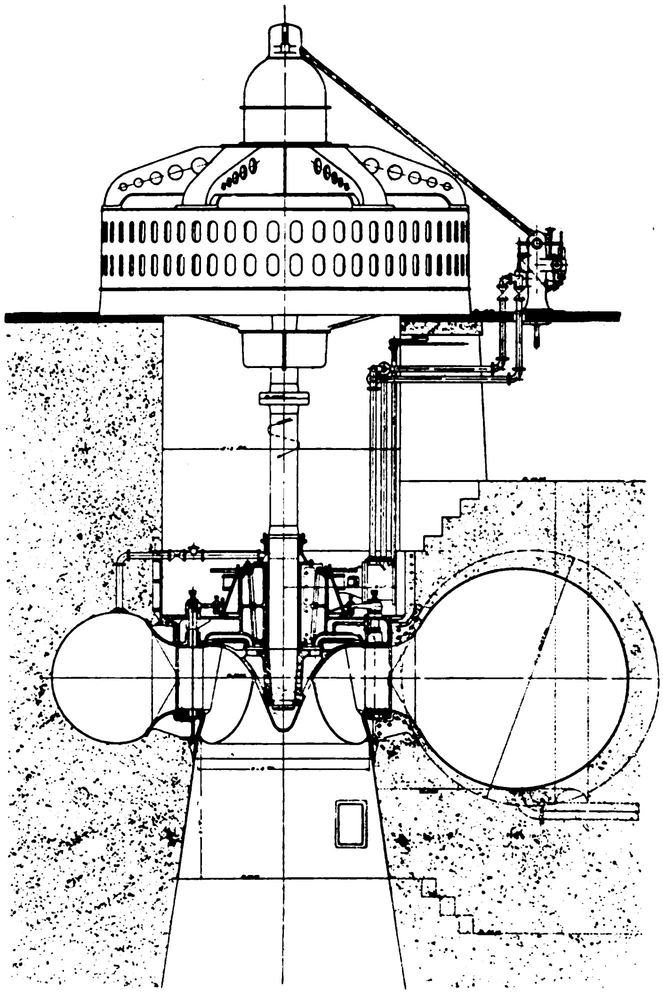

Fig. 18—Vertical Hydroelectric Unit with Imbedded, Circular Section, Plate Steel Spiral Casing
Governor flyballs mounted directly on main shaft.

Governors and Governing

In the case of poor speed regulation the governor is usually charged with the failure to perform, whereas actually the governor itself is only one of three problems entering into the governing of a waterwheel unit as set forth above. The function of the waterwheel governor in itself is the moving of the guide vanes a

proper amount in the proper time, and the readjusting of the guide vanes to the proper conditions of power and speed after the pressure rises produced by the movement of the vanes have been dissipated and conditions have returned to normal for that required power. The waterwheel governor has to perform more functions than any other type of governing apparatus, since it must move the gates to control the rise of pressure in the pipe line and the rise of speed caused by it.

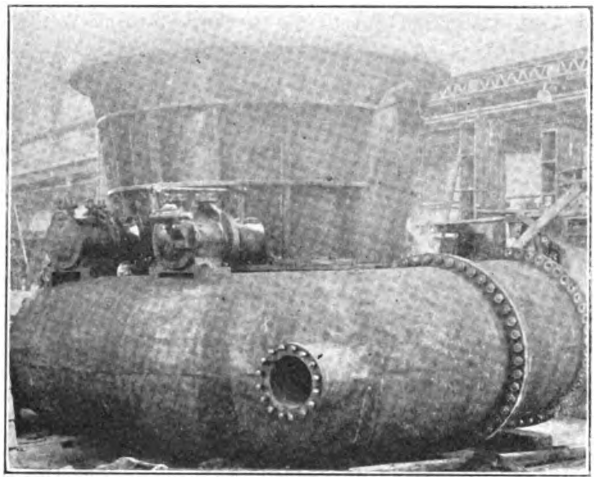

FIG. 19—11,000-H. P. VERTICAL-SHAFT TURBINE
Single-runner, cast iron, spiral-cased type, 360-rev. per min., 258-ft. head. Supporting barrel ready for generator.

A centrifugal flyball imparts motion to the center of a floating lever and the springs of the flyball are usually designed so that the governing mechanism is caused to operate quickly from wide open to closed position and vice versa when the speed has changed in the same time through a range of 20 per cent to 35 per cent of normal, this percentage selected depending upon the $W R^2$ of the revolving parts and the relative inertia of the water to be handled. After this sudden change of speed and motion of gates has taken place then compensation must take place to bring the speed back to normal. This is accomplished through a compensating dash pot introduced between a connection to the shifting ring and the end of the floating lever opposite that to which the regulating valve is connected. This dash-pot arrangement is so devised that for slow changes of load from no-load to full load the drop in speed may be zero or may be 2 per cent for parallel operation as per adjustment of the governor, but for quick changes of speed the gates can be closed or opened only by a change of speed from 20 per cent to 35 per cent as may be adjusted, thus introducing the time element, because the proper $W R^2$ will require time for the absorption of the uncontrolled energy.

Modern hydraulic governors are so sensitive that a change of speed of less than ¼ of 1 per cent will serve to move the gates to cause an adjustment of the guide vanes, and consequently the flow of water to compensate for the speed change. The conditions of inertia and $W R^2$ introduce dangerous factors into the regulation of the plant. These faetors are controlled through the time element of motion of the gates. This time element is dependent upon the reliable motion of the flyballs, consequently some means of reliable and effectively fixing the time of the flyballs with reference to the speed of the unit is very desirable in plants having bad conditions for regulation.

Fig. 11 shows a type of self-contained governor which is eminently suited for low-head open-flume plants. The particular governors herein shown are self-contained, having no interconnections; they have now been in operation seven years, and a recent examination of the plant showed that at no time has it been found advisable to have interconnecting piping between the governors.

Fig. 12 shows a directly connected flyball which has been used on a good many of the large plants. This type of flyball avoids the use of belts and the possibility of shut-down from their breakage, and also avoids the gears with the necessary small bearings on the horizontal jack-shaft.

Fig. 13 shows the governor stand for controlling the gates of the 37,500- h. p. unit of the Niagara Falls Power Company. In this particular design the operating fluid is supplied from a central oiling system. The operating fluid is water containing a percentage of oil.

INTEGRAL GOVERNORS

The latest advance in the art is that of the integral governor illustrated in Fig. 14, wherein it will be noted that the governor motion is imparted by flyballs

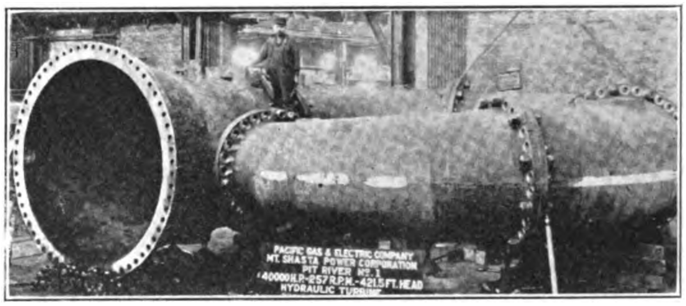

FIG. 20—CAST STEEL SPIRAL CASING
Having a thickness of three inches to withstand a head of 421.5 feet.

mounted directly upon the main shaft and the operating fluid is controlled by operating valves and governor mechanism located immediately on one of the operating cylinders connecting to the shifting ring directly through reach rods. The hand-control mechanism is located on the other operating cylinder. By means of this design we come back to the accepted practise in steam turbines, steam and gas engine design, wherein the governing mechanism is an integral part of the prime mover. The waterwheel governor has so many

functions to perform that it is necessarily complicated, and in the early development of the art the governors were made by companies separate from the waterwheel builders; consequently it came to be the accepted practise to consider the governors as a mechanism unto themselves. The present waterwheel governors, however, are so strong in design and reliable in operation that they do not necessarily have to be located

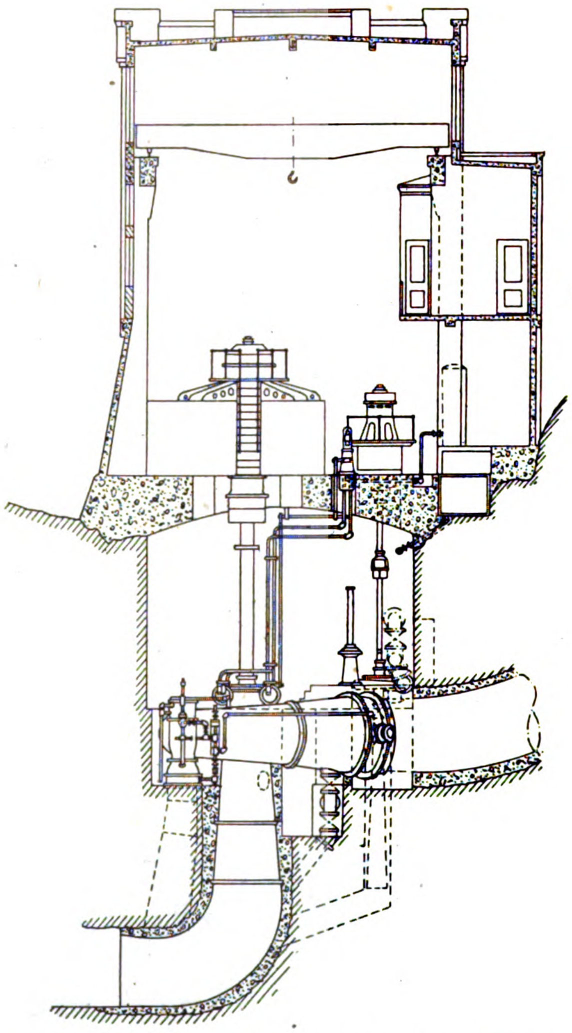

Fig. 21—Power House of Kerckhoff Plant of San Joaquin Light & Power Co.

Containing three units, each 15,000-h. p., 315-ft. head, 360-rev. per min. Butterfly valves, pressure regulators, curved draft tubes, and direct-connected flyballs.

on the generator floor immediately under the control of the operator, particularly since the unit may be controlled through a small synchronizing motor from the switchboard. The trend is toward the further simplification of the governor equipment and it is believed by the writer that we will in time come to the self-contained governor with no interconnection between the pressure systems of the several governors as is now frequently the case. Certainly the complicated central system with large sizes of piping required is not receiving the sanction of the buyers as much as formerly. A step in the right direction is the design of the Wateree Power Company, having direct-connected flyballs and the pump which provides the oil pressure for operating the governor driven through gears from the main turbine shaft, as shown in Fig. 15. In the case of the Mount Shasta Power Company the switchboard gallery is located above the main generator floor, and by adopting the integral governor the floor men are automatically placed on the turbine deck.

Turbine Casing

In low-head open-flume plants the casing is omitted but the walls of the flume are frequently shaped to form more or less of an open spiral so that the water may be directed smoothly to the runner. It is of prime importance that the water flowing to the guide vanes be kept free from eddies and whirls and as nearly an ideal stream flow as possible. It has been found and determined definitely that disturbed flow does increase the efficiency of a waterwheel unit, although the loss of head by that disturbed flow cannot be determined in the stream entering the unit. An analogous condition to that of disturbed water flowing through a runner is that of water flowing over a weir. Small eddies or cross currents in the stream flow approaching the weir, although so slowly and quietly as to be practically negative, and are certainly not sufficient to break the surface of the water; yet they produce breaks and notches in the weir crest several inches deep, when they flow over the weir. If such disturbances are occasioned in the flow over a weir, which is accompanied by such small surface disturbances, how much greater must be the action within the guide vanes and runner where the velocities are much higher, by disturbed conditions of flow in a pipe where the eddies and whirls may easily be many times that shown on the surface of the water back of the weir. The result of this disturbance has been definitely shown in the decrease of efficiency of the waterwheel.

The spiral casing affords the best means of conveying the water from the pipe line or forebay to the speed ring placed around the guide vanes. The spiral should be proportioned not exactly as per the decrease of the water as it passes through the annular opening through the speed ring to the guide vanes, but the casing should be kept slightly larger toward its smaller end. Water flows around an elbow at greater velocity on the short radius of the elbow than on the long radius of the elbow, and consequently, this higher velocity on the inner radius of flow is very much accentuated since the angle of flow is through 360 deg. in the spiral casing instead of 90 deg. in case of the elbow, consequently, as the velocity is increased on the inner portion of the spiral casing, the area of the spiral should be increased so as to reduce, if possible, the average velocity and consequently maintain the velocity at the inner radius of the spiral as nearly a uniform velocity around the casing as possible.

Concrete spiral casings of rectangular cross-sections

have been used in many plants with success, but the present trend in this connection is toward concrete spiral casings having circular cross-sections, with reinforcing rods in the concrete around this circular section, with either end of the reinforcing rod secured to the flanges of the speed ring. A concrete spiral casing of this type is illustrated by Fig. 16. Concrete spiral casings are suitable for heads up to 70 feet or 80 feet only when the superstructure of the power house is imposed on top of the spiral casing to avoid the tension in the reinforcing rods and in the concrete.

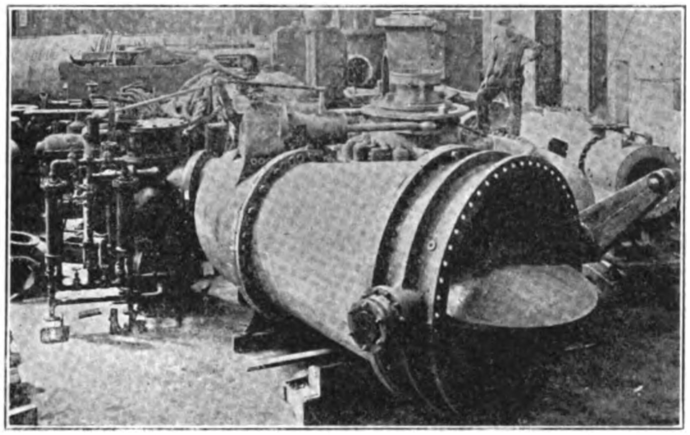

FIG. 22—SHOP ASSEMBLY OF 15,000-H. P. TURBINE UNIT
315-ft. head, 360-rev. per min.
84-in. butterfly valve, pressure regulator, and regulating cylinders.

A good design of power house, adopting concrete spiral casing reinforced in the manner above mentioned, combined with a section of the dam, is illustrated in Fig. 17. In this design the overturning of force the water against the upstream face of the dam is transmitted through the concrete to the top of the spiral casing and reacts to resist the upward forces produced by the pressure within the spiral casing. Fig. 18 shows a plate steel circular section spiral casing installed at the Lookout Shoals Plant of the Southern Power Company. The head obtained at this plant is 80 feet. This type of casing has been used very extensively during the last eight years on heads varying from 30 feet up to 215 feet. In the latter case the diameter of the inlet to the spiral casing was 11 feet and the thickness of the plate at this diameter was ⅞ inch. Larger casings with heavier plates are being contemplated for similar heads. The advantage of this casing is its cheapness in first cost, its resistance to sudden shocks and its ease of transportation.

Cast iron spiral casings are frequently employed, such as are illustrated in Fig. 19. This casing is made in two parts and the unit develops 11,000 horse power under 258 feet head at 360 rev. per min.

The cast steel spiral casing illustrated in Fig. 20, being built for the Mt. Shasta Power Corporation, embodies the latest improvements in high-head spiral casings. The waterwheel is equipped with twenty guide vanes, the casing has ten speed vane ribs, and the casing is divided naturally into five sections each with two speed vane ribs. The ribs are cast integral with the casing. Special provisions were used in preventing casting strains in the making of these castings. Each of the speed vanes are of a definite design decreasing in size around toward the small end of the casing and varying in angular relation to the casing to accommodate each particular speed vane to the flow of the water at that point.

There is no hard and fast line fixing the use of one type or the other of spiral casings but, usually, the configuration of the ground surface at the location of the plant determines the particular type of development best suited for the maximum development of efficiency, taking into consideration economy of construction.

VERTICAL VS. HORIZONTAL UNITS

The trend of modern design is toward larger and larger units and toward designs which will give maximum amount of power from the energy of the water available. This naturally leads to the single-runner, vertical unit because, as pointed out, the larger the waterwheel and generator, the more nearly in accord are the economical speeds of the two. The larger the waterwheel runner, the more difficult it is to place the runner with the shaft in horizontal position. The higher the specific speed of the runner, the greater the energy in the discharged water; consequently, the more important it is to adopt a regaining device which will return the maximum amount of that energy to the runner for effective development of power.

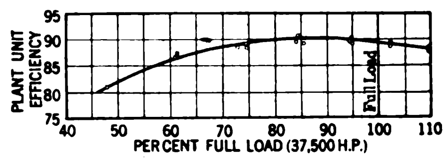

FIG. 23—CURVE SHOWING COMBINED EFFICIENCY OF ALLIS-CHALMERS TURBINE AND GENERATOR
37,500-h. p., 214-ft. head, 150-rev. per min.

CONTROL VALVES

A recent invention comprising snap rings disposed around the periphery of the disk of butterfly valves provides a means of making this type of valve substantially water-tight. This should bring this type of valve into more general use because of its great simplicity and reliability in operation.

Fig. 22 shows the butterfly valve constructed for the Kerckhoff Plant of the San Joaquin Light & Power Corporation, having a diameter of 84 inches and operating under a head of 315 feet. Note the simplicity of a valve of this type, and the small obstruction which the open wicket causes to the flow of the water through it.

Power House Setting

It is really a misnomer to say modern power house setting, because each power development requires a setting peculiar to its location, and that setting is modern only when there is brought to bear in its design experience gained on other power plants. One type of development, if we may call it such, is that exemplified in the Wateree Plant of the Southern Power Company, wherein the power house is made a part of the dam. At this location there was sufficient width in the river to place the power house as a part of the dam and thereby save expense. Another location of apparently similar conditions might necessitate a spillway of the full width from bank to bank which would force the development of possibly a new type of power house or the best of the existing types of power house.

The best power house setting can only be obtained by a careful analysis of all the factors, the aim being, as always, to produce a plant which will after years of operation prove the least expensive, considering not only the original investment, but the operating and depreciation charges.

Electrical Terminal Facilities

BY COMMANDER C. S. McDOWELL
U.S.Navy

THE other papers presented at this meeting deal with the application of electricity on shipboard. Proper terminals are closely allied with shipping and very necessary for its operation, and it is, therefore. the purpose of this paper to show in a general way the necessity of electrifying terminals, presenting to shipping men some knowledge of what can be done with electrical apparatus to simplify their problems, and to present to electrical engineers some idea of such shipping problems as concern terminals.

In considering the question of our American Merchant Marine, it appears probable that the subject of suitable terminals has not received the attention which it deserves. Transportation is the necessary means of conveying the products of the factories, mills, mines and farms to the consumer, and as we must look to the markets of the world for the customers of a certain part of our products, both raw and finished, every one who is at all concerned in the production of material in this country is affected by the efficiency of our means of transportation of products to the ultimate consumer, situated as may be at the ends of the earth. Transportation is as much a part of the cost of production as labor or material. Ordinarily, however, in thinking of transportation from our factories, mines grain elevators, etc., to the foreign purchaser, we consider only the necessity of getting the product to the seaport by rail or boat, and the shipping required to carry it across the sea. The great importance of the connecting link, the terminal facilities, required for the transference of products from the one system of transport to the other, was forcefully brought home to most of us during the war. The amount of material piled up on the Jersey Meadows, for instance, made many a manufacturer wonder at the insistent demand made on him to rush his orders for foreign shipment, and this congestion at our ports was not primarily due to the lack of ships, but to the inability to get the materials to the ships, and quickly loaded on them. Thus, if we assume that under the congested terminal conditions during the war, it took ten weeks for a ship to make a round trip, while with adequate terminal facilities the same ship could make the round trip in five weeks, it is seen that terminals are in reality the neck of the bottle and that the mere building of ships and doubling or quadrupling our merchant fleet does not increase our ability to transport freight in the same ratio.

To operate our merchant marine economically in peace time, and compete with other countries, it is highly important that the "turn around" should be cut down to the minimum. There is no particular purpose in providing economical propelling and auxiliary machinery on shipboard, if all the saving obtained by such improvements is eaten up by unnecessary delays in port, waiting to unload and load cargo.

We need fewer and higher skilled, better paid shipmen and dockmen with the very latest, speediest machines for loading and unloading. Such facilities both ashore and on board ship, combined with the higher skill of America in operating and caring for machinery is our chance to offset the higher wage paid our seamen, and put us on a competitive footing with our friends in the Atlantic or in the Pacific.

The time has now arrived when active steps must be taken toward constructing wharfage and warehouse facilities adequate for the use of our ever increasing Merchant Marine. Most cities have restricted their activities simply to the construction of piers, with little consideration for the development of adequate storage and freight handling facilities.

No standard layout can be established as applicable to all terminals, as the variables encountered are too numerous. Thus, the kind of cargo to be handled, (bulk, as coal, wheat, ore, etc., uniform package as

---

Presented at the Joint Meeting of the N. Y. Section of the American Institute of Electrical Engineers and the Metropolitan Section of the American Society of Mechanical Engineers, New York, N. Y., January 28, 1921.

bagged sugar, or general cargo), determines the facilities that are required. In addition, the methods of receipt of cargo for ocean shipment and of distribution of the cargo from ships, whether by rail, by lighter, by truck, or storage in local warehouses, influence the apparatus required. Also, the types of ships docking at a terminal determine somewhat the mechanical facilities required on the pier.

The simplest method and the one allowing the most economical handling of freight is the one where standard ships run between two definite ports, always utilize the same terminals and carry only bulk or standard package freight. Under such conditions the special problem may be solved by installation of permanent electrically operated conveyers of different types, electric cranes, mechanical unloaders, etc., and cargo handled in much the same manner at ocean terminals as ore is handled on the Great Lakes. The above condition also permits the installation of all the cargo handling apparatus on shore and eliminates the present steam winch, which is notoriously inefficient, from the ship; it also, by the same elimination, puts the cargo handling gear where it is used practically continuously and removes this gear from the ship where it has been a large expense to install and keep in order, being used for a short time only at the end of each voyage.

Under such conditions, the ship becomes a freight carrier and is analogous in this respect to a railroad car or barge.

Unfortunately, the conditions as outlined above are seldom or never met with. A near approach to it, though, is the shipment of export coal. Up to twenty years ago the most efficient type of plant consisted of a pier with railroad tracks on two levels, the loaded cars running out on the high level, discharging their load at a height of some 40 feet above the water into the chutes which fed directly in the cargo holds. The cars then proceeded to the end of the pier where they were lowered by a platform elevator or a drop table, returning to the shore over the lower line of track, both lines being so graded that the cars traveled by gravity. The limitation in this system lay in the speed with which cars could be handled, and the capacity did not exceed 300 or 400 tons per hour. An objection to the system was the fact that a very large amount of rolling stock was tied up, it being necessary to have a full ship's cargo waiting on wheels at the pier.

About twenty years ago one of the above type of piers was remodeled in the following manner: At the shore end large hopper bottom bins were built which held an entire ship's cargo of coal. Through a tunnel under these bins, which were provided with gates in the bottom, there was run a 36-in. belt conveyer, which in turn fed a second conveyer, which ran the entire length of the pier. This conveyer discharged the coal at several points simultaneously, and provided a loading capacity of 800 tons per hour. This system also greatly reduced the number of cars operating between the mines and the pier, as each car was immediately released after dumping its coal into the storage bin.

Although other types of piers with gravity feed have been built in the past twenty years, the present trend is apparently toward the belt conveyer system, electrically driven. Thus, one of the latest coal piers built is the loading pier for the Baltimore and Ohio Railroad at Curtis Bay, Baltimore, at which the cars are dumped in the yard on shore on the tail end of the system of four parallel 60-in. belt conveyers, each of which discharges to the vessel by means of a large "tripper" consisting of a movable steel tower, which carries pulleys over which the belt turns back on itself to discharge its load.

The above is given as an example of what may be done in the loading of a uniform bulk cargo, in the case of coal piers; the proposition is simply one of loading; if unloading is to be provided for, an entirely different type of equipment is required, and in such a case for bulk cargoes, separate piers are usually provided. Unloading of bulk cargoes has not been brought to the same degree of efficiency, as a record on the Lakes of 2½ hours unloading for a 10,000-ton vessel, as compared with 23 minutes for loading it, will show. The Hulett "grasshopper" unloader is now in general use and consists essentially of a massive frame or walking beam, whose front end rests on the face of the dock, and the rear end on a slightly raised concrete wall. On this frame is a carriage moving backwards and forwards over the trough. The outer ends of the walking beam are legs which reach down into the hold; the whole mechanism being operated by one man. When a load of 15 to 20 tons is elevated by the bucket clear of the vessel, the carriage runs back on the main frame until the bucket is over the weighing hopper or trough and there the load is released. The weighing hopper moves only between the main legs of the machine. A cable runs along side of each track continuously and the movement of cars is taken care of by the cable. An operator pulls a lever on the mechanical clamp which is attached to the train and moves the train a car length for the next load.

The cheapening of the cost of unloading by the successive steps by which the process has been improved since 1880 is shown by the following:

Cost of unloading a ton of coal with wheelbarrows	$0.56
With Brown machine and shovelers	0.28
With Brown fast plants	0.12
With Hulett fast plants	0.04

Another method where efficient mechanical appraatus for loading and unloading may be employed is in the uniform package freight, which consists of coffee, sugar, seed, rice, paper in rolls, crates of fruit, bananas

in bunches, cotton seed cake, and many other commodities of similar character.

At the Port of New Orleans where bananas are unloaded in greater quantities than in any other port in this country, the handling of the unloading by mechanical devices has been developed until practically all of the bananas are now unloaded by machines. The general plan is to employ unloaders of a structural steel framework supported by railway trucks running on standard railway tracks set close to and parallel with the face of the wharf. The framework supports a double boom which can be adjusted into position over the hatchway of the ship. Over the booms constant running chains are installed which are equipped to carry several bunches of bananas in huge slings. The chain is lowered through the hatchway by means of the adjustable booms and after being placed into position the bananas are placed into this sling and removed from the hold to be deposited on a receiving table on the wharf. Trolley conveyers are utilized for distributing the bunches of bananas to refrigerator cars located on railroad sidings, running perpendicular to the face of the wharf, these conveyers having branches to each siding.

Mechanical unloaders of a construction similar to that given above have been designed for handling of miscellaneous cargoes and are installed, or being installed at some army bases. They consist of structural framework with double boom and constant running chain carriers similar to the one mentioned above. The plan in this instance is to carry small trucks loaded with miscellaneous cargoes. These trucks are fitted with small wheels so that when they are deposited on the wharf or in the storage rooms they are automatically released and can be wheeled to any position or location desired. For carrying material within the warehouse, it is planned to carry these same trucks automatically on overhead trackways and have them automatically deposited wherever wanted. This type of apparatus is reversible and can be used for both loading and unloading ships.

In the case of bags and bales, not very much progress has been made in the utilization of continuous movement apparatus, although unloaders of the conveyer or continuous chain type have been developed and installed in some cases. The electric crane has been developed to such efficiency that it is probable that continuous movement unloading machinery would have a hard time competing with it. Bags and crates unloaded through hatches are lifted in the rope sling by boom or crane and deposited on the wharf deck for handling. In some cases, however, conveyers have been built with a movable section, permitting it to be extended to the deck of the ship where bags, barrels, etc., are fed to slings which lower a sling full at a time into the hold. In case of unloading, the slings are used to take the freight from the hold.

Speaking generally, it is easy to provide mechanical handling facilities for bulk cargo, or for package cargo, when the latter is uniform. The difficult proposition is to provide facilities for miscellaneous cargo, and as a rule, the ships leaving our ports carry a mixture of almost everything from kegs of nails and sacks of grain, to steel rails and crated automobiles, and for such a mixture there is no adequate system of mechanical handling.

In this connection it may be noted that the stevedore is required not only to handle the freight from the dock to the vessel, but to so place it and secure it in the vessel, that stability and center of gravity may remain just right, and that the cargo itself may not shift and be injured by the constant movement of a vessel in an ocean voyage.

For the handling of such miscellaneous cargo, an electric crane is most essential and it appears preferable that the cargo be handled directly into the ship's hold with the crane without the use of the ship's booms. The question of the number of cranes to be provided at the pier depends to a great extent upon the character of the pier itself; if room and facilities are available for feeding cargoes to each hatch, then there should be sufficient cranes to work all hatches. It may be noted that in new basins at Hamburg the cranes are spaced every 100 feet. When the cargo is to be distributed in part or in whole by lighters from a pier, a desirable arrangement is to provide cranes on dolphins on the offshore side of the ship for loading and unloading to lighters, at the same time the cargo is being handled on the pier. Incidentally, in connection with electric cranes, it should be noted that electric heaters are desirable for the comfort of the operator, in cold weather.

It is not the purpose of this paper to go into the design of the pier itself, but it is presumed that a marine pier or terminal will be provided with sufficient space to handle both incoming and outgoing cargo without confusion.

On the wharf, itself, means are required for handling the loads for conveyers or crane hoists to and from the ship, and the old method which is common today on many of our wharves is the use of the hand truck. For short movements the hand truck cannot properly be dispensed with, but for most movements on the wharf, the electric truck or tractor with trailer, or the continuous movement, portable piler with trailer, can and should supersede the hand truck, and eliminate many of the men now required to handle cargo. These trucks, or tractors, are usually of the storage battery type and have demonstrated their thorough usefulness.

For handling cargo on the pier, an overhead trolley hoist, either of the monorail type or of the double track type, commonly used in large factories, has been developed.

For stacking freight at the terminal a tiering machine has been utilized which allows not only much more rapid tiering with the elimination of most of the

manual labor, but also allows tiering to much greater heights.

In some cases two-decked piers have been built in order to save space, and in order to keep incoming and outgoing freight separated without moving the ship. This form of pier usually requires a connection between the two decks and involves elevating and lowering from one deck to the other. These movements are accomplished by electric freight elevators, by continuous movement parcel elevators, etc.

For moving freight cars at the terminal, electric locomotives, either of the trolley type or storage battery type, may be provided, or electric gypsies installed. For handling ships' lines, and moving ships at the pier, electric winches can be used, and in addition, electric winches of the permanent or portable type can be utilized for whips, either for handling cargo on the ships or for handling on the pier itself.

To sum up, the following are some of the electrical apparatus and devices which are available for use at terminals: Cranes; conveyers, belt or chain type; trucks; tractors with trailers; tiering machines; pilers; mechanical unloaders; winches, permanent or portable; freight elevators; overhead trolley hoists; locomotives.

The electrical supply at the terminal should be of the same voltage and kind of current (d-c. generally) as that in use on board ships which are to be handled. This will allow the ship to receive electric current from the pier for the ship's purposes, and the ship generators can be shut down while at the dock, so that all overhauling on the ship's steam and electric system can be made at the same time as freight is being discharged and received. This should materially reduce the average "turn around" time and allow the ship's main and auxiliary machinery to be given a thorough examination, and overhauling, while in port.

It is believed that modern port terminals offer a good electric load, which central stations should endeavor to develop in order to increase the efficiency of our terminals, as well as to improve the load factor of central stations.

It has been stated that it is extremely difficult to provide efficient mechanical handling apparatus which can take care of all types of miscellaneous cargo. Economical progress in the handling of ocean freight can be greatly assisted by the construction of large warehouses on shore in which various kinds of miscellaneous cargo can be classified and handled by suitable machinery. It is possible that in the future terminal companies may be developed to act much as the railroad and other transportation companies, so that freight may be consigned to them as one link in a through bill of lading, from the producer to the customer. It is conceivable, under such conditions, that special piers will be utilized for different classes of products, the terminal company classifying freight from the mainland, and segregating it at the piers for handling such material, and having ships assigned for carrying that particular type of products only, and making shipments in shipload lots of one class of material. Such a procedure would, undoubtedly, materially reduce terminal charges and permit the operation of our Merchant Marine under more efficient conditions.

NOTE: In preparing the above, the following sources were consulted: "Ports and Terminal Facilities," McElwee; General Electric Company, Westinghouse Electric and Manufacturing Company, The Lampson Company, Robins Conveying Belt Company, etc.

CIRCULAR ON TELEPHONE SERVICE

A circular on Telephone Service has been published by the Bureau of Standards, Washington, D. C.

The product which a telephone company sells is service but from an analytical standpoint the service as a whole must be divided into its elementary characteristics which are peculiar to the nature of the service and to the manner in which it is rendered.

Service in general is considered in the introductory section while descriptions of the telephone plant and its operation are given in sections which respectively consider developments of the telephone art, equipment of manual systems, equipment of automatic systems, outside line construction, and telephone traffic. These are followed by the section on the principal elements of telephone service.

Attention is especially directed to the section entitled "Principal Elements of Telephone Service." Here are considered those service characteristics which are outlined in the determination of the grade of service and thus there is furnished a basis for future work along the lines of service standards. The elements are considered in groups each having common service relations and the most important factors involved in each case are enumerated and their relations to the grade of service are explained.

A section on the subject of public relations has been included to cover those phases of telephone service which receive attention by regulatory commissions both federal and state. Plant extensions, abandonment of service, physical connections, accounting, valuation, rates, rate schedules, contracts, collections, and discrimination have been considered. A conclusion is drawn regarding the subject of service standards. The rapid and extensive development of the telephone industry is indicated by statistics given in the form of an appendix.

The circular, No. 112, may be obtained from the Superintendent of Documents, Washington, D. C., at 65 cents per copy.

Technical Committee Annual Reports, 1920-1921

(Concluded from page 595 of JOURNAL for July, 1921.)

PROTECTIVE DEVICES COMMITTEE

To the Board of Directors:

Several years ago it appeared that the work of the Protective Devices Committee would be conducted to better advantage if it should assume that the Committee would be largely reappointed from year to year and that it might undertake investigations which could not be completed within any one fiscal year. Since that time it has practically lost all interest in the fiscal year except for the purpose of making its annual report in accordance with the Constitution. The investigations of its sub-committees has continued from year to year and on several occasions the sub-committees have presented their report in the form of a paper before the Institute.

At the present time the work of several sub-committees has not progressed to a stage where they are ready to present any lengthy reports in the form of papers, so that the present reports can be considered as progress reports. Several of the subjects under investigation by the Committee are discussed in the following summary.

Current Limiting Reactors

By F. E. RICKETTS

In view of the papers presented at the Annual Convention last year on this subject, this sub-committee has been able to collect but little data that would be of interest.

Certain papers presented at last year's Annual Meeting went into much detail in explaining the possibility of high-voltage stresses between turns of reactors during abnormal conditions of operation. Failures that had occurred in certain forms of reactors where bare conductors were supported by concrete were attributed to this cause. Since certain contributors to the discussion of these papers disagreed with this statement and, as it has since been fairly definitely determined that some of the failures were due to mechanical weakness rather than to high voltages, it seems proper to call attention again to this subject. This type of reactor has since been strengthened by adding more concrete supports for the conductors and it appears that the trouble has been thereby overcome.

Certain tests to determine the rupturing capacity of oil circuit breakers have been made that indicated that reactors while reducing the maximum current may subject circuit breakers to additional strains by tending to prevent the circuit from being interrupted at the zero value of current, which is the point at which a circuit-breaker usually interrupts the circuit in the absence of reactance.

System Troubles

By A. A. MEYER

From replies to a request for data on system troubles experienced during the year 1920, information was received from a number of the larger companies.

Some of the replies include numerous cases of improper functioning of relays, but which were not serious in affecting the system. They could hardly be classed in the same category the committee considered for investigation. Moreover, several of such cases were cited without any word of explanation as to the possible cause of improper functioning. It would take considerable time and study to analyze all such cases of false tripping and draw any valuable deductions. I believe the committee should confine its attention first to the cases which seriously affect the system as a whole.

Among the most noteworthy cases, the following performances and factors are of interest as affecting the system as a whole. Relays are reported as functioning too promiscuously on a transmission system. Instead of the relays close to the source of trouble functioning and isolating the trouble at once, these relays fail for various reasons, and as a consequence, relays elsewhere on the system operate and shut down large sections, if not the entire system. The reasons for the relays failing to isolate only the section in trouble are such as, incorrect connections, improper settings and shortcomings in the relays themselves when called upon under abnormal conditions on the system, accompanied usually by low voltage. Several cases were cited where low pressure, delayed reverse power relays from functioning in the time that was intended. Some transmission systems comprise a series of sections with graded settings, the relays in each section being set a trifle above or below the settings on the neighboring sections. Where the series contains many sections the increments in the settings necessarily have to be small to avoid too high a setting on the section close to the source. In some cases the increments are too low and due to slow circuit breaker operation, isolation of a fault is sometimes obtained by cutting out sections in additions to the desired one. In other cases the increments are too large and a fault occurring in a section close to the source is held connected too long to a system, and as a result the initial fault drags so hard on the generators as to throw them out of step, and a real system disturbance follows. Some desire has been expressed for the need of current limiting feeder reactors to avoid such a heavy drag on the generators due to a fault near the station. System troubles have also arisen out of small initial troubles in several cases due to circuit breakers of inadequate interrupting capacity. Duties on circuit

breakers not infrequently outgrow their capacity on fast growing systems. It is quite essential that the capacity be checked up occasionally and compared to the duty which might be expected.

Another noteworthy factor responsible for system troubles comes through the practise of providing low-voltage releases on power house auxiliaries. In several cases it was reported that low main bus pressure caused the plant auxiliaries to drop off, thereby making matters much worse. The practise of providing such protection on plant auxiliaries needs careful reconsideration in, no doubt, many cases.

In the above, reference has been made only to some of the short-comings of relay schemes. Outside of these, troubles have also arisen through electrolytic lightning arresters. One company reports several cases of fire, some of which were quite serious, due to the arrester itself failing through some slight mistreatment. The hazard is greater than perhaps realized by many users of electrolytic arresters.

The above are the main items of interest brought out in the replies to the committee's request for a report on system troubles. No doubt there are several other cases of system trouble still unreported. It is hoped that some of these will be reported at a later date.

Lightning Arresters

By F. L. HUNT

The sub-committee on Lightning Arresters has given consideration to the lightning arrester subject, with a view to determining what might be done by the members of the Protective Devices Committee to increase the usefulness of lightning arresters as protective devices.

Many engineers have questioned the necessity for using lightning arresters on all circuits because the results obtained from their use have been more or less unsatisfactory, due in part to inherent defects in the designs of the arresters, and in many cases on account of misapplication of the equipment that is available.

In order to obtain information regarding the present practise of engineers and operating companies in the use of lightning arresters, and to obtain as much information as possible regarding the defects which have developed in the commercial arresters as produced today, and the unsatisfactory experiences which have been had in their use, a short questionnaire was sent to members of the Protective Devices Committee and to a few other operating engineers. A summary of these data is given herein.

Twenty-nine copies of the questionnaire given below were sent out and twenty replies have been received up to the present time. We were also able to arrange a conference with Mr. R. A. Paine, who has collected data on lightning arrester practise to be used by the Overhead Systems Committee of the N. E. L. A., and to make use of those data so far as they applied to the questions under consideration by our committee. The sub-committee has not had an opportunity as a whole to discuss or consider the data which have been collected. It is recommended that such consideration be given, however, either by the sub-committee or by the main Committee, in order that the greatest benefit may be obtained from these data. The questionnaire sent out was as follows:

1. What general type of lightning arrester would you recommend for feeder circuits of 1000-kw. capacity or greater, leading from a generating station or important substation?

(a)	10,000 volts.	(c)	66,000 volts.
(b)	33,000 volts.	(d)	150,000 volts.

2. Under what circumtances, if any, do you think it advisable to omit lightning arresters entirely from circuits of the above description?

3. How many lightning arresters would you recommend and what general class of arrester for a substation from which power was being distributed by six 22,000-volt overhead circuits? (Consider only 22,000-volt side of substation).

4. On what class of circuits of 10,000 volts and above would you advocate the use of horn gap lightning arresters?

In addition to the points raised above, the committee is especially anxious to get the fullest possible expression of your opinion as to the objectionable features in the principal types of lightning arresters used today on voltages of 10,000 and above.

We believe the work of the Protective Devices Committee in studying the uses and improvements desirable for protective devices can make progress on the lightning arrester problem by obtaining the reasons for the adverse opinions which exist. If you are willing to give us, therefore, the facts or experiences on which you base any objections you may have, it will be of great service to the committee.

The replies to this questionnaire indicate that the general practise is remarkably uniform. A very large majority of the engineers replying to this questionnaire agrees in its recommendations on each of the points raised. There are a few notable exceptions, however, and a few opinions expressed which vary quite widely from the majority of opinions, but which are given by men of such broad experience and in such responsible positions, and are based on such definite cases of experience that we believe it advisable to give especial attention to these statements. Since we are all familiar with the general practise on these points as is evidenced by the majority of opinions expressed in the answers to these questions, we are perhaps warranted in giving especial attention to the exceptions to the rule.

The answers to Question No. 1 were as follows:

(a) 16 — Oxide film
15 — Aluminum cell
1 — Condenser resistance with horn in parallel to the condenser
1 — Compression chamber
1 — Horn gap with water resistance

(b) 16 — Oxide film
14 — Aluminum cell
1 — No arrester
1 — Horn gap with water resistance

(c) 14 — Oxide film
13 — Aluminum cell
1 — Bennett type
2 — Horn gap with water resistance
1 — No arrester

(d) 13 — Oxide film
13 — Aluminum cell
1 — Bennett type
1 — Horn gap with water resistance
1 — No arrester

It should be noted in the above answers that the majority of those recommending oxide film recommend the aliminum cell also.

Answers to Question No. 2 show 12 who believe there are no cases where arresters should be omitted entirely. There are several who are willing that they should be omitted at small substations or on short and unimportant lines, or at points not subject to lightning. One omits arresters for 30,000 volts and over, one for 66,000 volts and over, and two on 150,000 volts and over. One omits arresters where apparatus of modern design is installed.

The answers to Question No. 3 are as follows:

13 — Recommend one arrester for each circuit, of which ten recommend the oxide film.
5 — Recommend one arrester on the bus.
1 — Recommends one arrester for each two circuits.
1 — Recommends one arrester for each transformer bank.

The answers to Question No. 4 are as follows:

11 — Do not recommend in any case the use of horn gap arresters.
4 — Recommend their use on unimportant circuits from small stations.
3 — Recommend their use with resistance in series on circuits of 12,000 volts or over.
1 — Recommends their use on 22-kv. circuits from substations.
1 — Recommends their use on all circuits over 10,000 volts.
1 — Recommends their use on customer's small substations.

Of the comments on the objectionable features of lightning arresters practically all the remarks were applied to aluminum cell arresters. The disfavor toward the horn gap is shown by the small number that recommends its use. Specific objections to this type were mentioned by a few, as follows:

One objection made which applies to nearly all classes of arresters is that the spark gap used in most designs reduces very much the protective qualities of any arrester, provided the arrester could be designed without a spark gap.

Referring to the aluminum cell arrester, six object to the fire hazard of the aluminum cell, eight object to the care and excessive attention required to keep the aluminum cell arrester in operating condition and in a condition to be a protection to the line, and one states that the mechanical features are poorly designed and do not stand up in service.

Extracts from some of the letters are as follows:

Operation erratic and protective qualities questionable.

Disturbances are set up by the discharge of horn gaps when used without resistance.

Do not stand up under service.

As to the objectionable features of the principal types of lightning arresters used on voltages of 10,000 volts and above, I presume by "principal types" you refer to aluminum electrolytic type and the oxide film types. My principal objection to these types of arresters is that they are dependent for their operation on somewhat obscure phenomena depending upon certain characteristics of the materials of which the arrester is constructed, these characteristics involving the action of films of very minute dimensions. In my opinion a multiplicity of elements of so minute a nature cannot be depended upon to provide the strength and reliability necessary for a lightning arrester.

* * * * *

I have witnessed a number of years of successful operation of large power plants with lightning protective equipment substantially as above, and during these years, at different times and places, both electrolytic and oxide film arresters have been tried out with indifferent success. I believe that all of the electrolytic arresters involved in this evolution have now destroyed themselves, while the horn gap-water barrel combination is still successfully performing its functions.

About two years ago I purchased 16 sets of oxide film arresters for 12,000-volt circuits. Only one of these sets, so far as I know, has had a discharge pass through it and this set was practically destroyed on this occasion. There was present at the time, it is true, an abnormal condition of high dynamic voltage, but I am positive that a water barrel horn gap type of arrester, as above suggested, would not have been injured. It is my opinion that better protection at much less cost can be obtained by means of home made apparatus of the type suggested than by spending large sums of money for hair-trigger types of arresters based on fine haired theories and obscure chemical reactions.

* * * * *

Past experience with lightning arresters makes it difficult if not impossible, to justify their expense particularly so at the high voltages. Where companies have made consistent efforts to get definite data in regard to apparatus failures with and without arrester protection, the results occasion distrust as to the effectiveness of the protection afforded by arresters. One of the companies affiliated with the .... Company has maintained a thorough record of this nature and finds that failures have occurred more frequently and have effected larger apparatus at installations protected with arresters than on other installations of lesser importance which have not been so protected. This is true both at 100 kv. and at 66 kv.

* * * * *

While it cannot yet be said that the omission of lightning arresters at the higher operating voltages is to be generally recommended, in view of the evidence at hand serious consideration should be given the subject and the justification for each new installation decided upon its merits.

* * * * *

We have kept careful records of apparatus failures on our high-voltage lines, and when we first began building these lines in 1910 we were of the opinion that it would certainly be necessary to have arresters to protect the apparatus. Our experience with arresters, however, soon demonstrated that it would be a cheaper thing to have spare transformers than it would be to repair the very large and expensive aluminum cell arresters. We finally, in 1912, stopped using them entirely, and our expense of maintenance has been materially reduced. We probably pay some penalty in first cost of rather expensive transformers, but we feel that we are justified in getting the very best and highest type of transformers and dispensing with the lightning arrester, and feel that from the standpoint of service and the standpoint of economy we have made a gain.

From an analysis of some of the reports on lightning arresters, and from a study of their designs, it appears that in order to secure the best protection, one of the paths through the lightning arrester should be a high current capacity path, that is, a path that will allow a large current to flow at the time of lightning discharge. If such a path is provided, the arrester will have a

lower maximum voltage across the terminals at time of discharge than will be the case if the discharge capacity or rate of discharge is limited by the insertion of a resistance. It is possible that with a resistance in series, the maximum voltage will be higher than the break-down potential of the apparatus or cables which the arrester is intended to protect.

In general, transformers intended for a normal operating pressure of about 25,000 volts will withstand somewhat higher potentials than underground cables for the same working pressure. This is due to the fact that transformer windings are submerged in oil which has a high dielectric puncture value, and in addition, the end turns of transformers are generally built with extra insulation which will withstand higher voltages than the remaining turns in the transformer, and as the frequency of lightning discharges increases with their potential, it is the end turns in transformer windings which are subjected to the greatest strains at the time of lightning discharges. This means that for the protection of underground cables which are connected to overhead lines, arresters should be used having a high current capacity at time of discharge such as the aluminum cell or the oxide film arrester, while transformer installations, for supplying individual customers, which are connected directly to the overhead lines may be protected by types of arresters which have a lower discharge capacity and therefore a somewhat higher maximum potential across the arrester at time of lightning discharge.

Circuit Breakers and Switches

By H. R. Woodrow

Your sub-committee has analyzed the replies to the questionnaire on oil circuit breakers which was sent out in cooperation with the Apparatus Committee of the N. E. L. A., and Power Switchboard and Oil Circuit Breaker Section of the Electric Power Club. A short abstract of the general conclusions from these replies was published in the March issue of the A. I. E. E. Journal.

The Apparatus Committee of the N. E. L. A. has prepared a detailed summary of these replies which will be presented before the N. E. L. A. at its annual meeting in Chicago on June 1, 1921.

From the discussion following the presentation of the paper on "Present Day Practise Limitations of Oil Circuit Breakers" at the midwinter convention, the following additional comments are made:

Rated Voltages. The present standards of the A. I. E. E. specify that oil circuit breakers shall be given a dielectric dry test consisting of the application of 2¼ times the rated voltage plus 2000 volts between the live parts and ground for 60 seconds. Although the questionnaire did not indicate in any way that such a test would not give adequate insulation it was brought out in discussion that some operating companies are purchasing apparatus of a voltage rating higher than the system voltage on which the apparatus is to be used.

It is recognized that the dielectric test recommended by the Standards of the A. I. E. E. must meet the requirements of average systems. It must also be recognized that systems not protected by adequate lightning arresters and systems of very large capacity may be subjected to voltage rises due to surges or lightning that will exceed the insulation values required by the Standards of the A. I. E. E. Taking those points into consideration, it is not recommended that these Standards for dielectric tests be changed. However, for systems that have characteristics, or inadequate lightning arrester protection, such that higher insulation is required, the present practise of selecting apparatus of the next higher voltage rating is endorsed.

Rated Continuous Current Carrying Capacity. As little trouble has been experienced from overheating of oil circuit breakers when carrying normal rated current, it is evident that if proper precautions are taken for alinement of current-carrying parts and ventilation of compartments, little trouble would be expected from this source.

Rated Momentary Current Carrying Capacity. As a few cases of trouble were reported from this source and as a result of the tests made by the New York Edison Company, it is recommended that oil circuit breakers be given a short-circuit current rating for periods of both one and five seconds.

Rated Interrupting Capacity. It appears from results of the questionnaire that the operating companies may require ratings on duty cycles other than the present recognized standard as given in the paper by Messrs. Hewlett, Burnham and Mahoney. There is considerable difference of opinion regarding the point of ending this duty cycle, the allowable condition of the breaker at that time, and what is considered satisfactory operation of the breaker.

It has been impossible to answer satisfactorily these questions at this time, and it is therefore suggested that this matter be given careful consideration by the next year's sub-committee.

General Comments. The subject of oil circuit breakers as reported by this committee was intended to cover the field of station breakers which would have to rupture large amounts of power rather infrequently, and is not intended to cover the subject of circuit breakers such as used in control equipment where they should be capable of interrupting full-load current a large number of times per hour for long continued periods and not be required to interrupt heavy short-circuit currents.

The activities of this sub-committee have been confined this year entirely to the subject of oil circuit breakers, and it is suggested that next year's sub-committee consider the question of rating and ruptur-

ing capacity of fuses, both of the power class and potential transformer class, in addition to following up the study on limitations of oil circuit breakers.

Schemes of Relay Protection

By E. A. HESTER

It is the function of the sub-committee on Schemes of Relay Protection to act as a clearing house for all information on protective relay schemes and to present this information in such a form that it will be an authoritative record of the progress of the art. The results of the first questionnaire, which was presented to the Institute in June, 1919, covered only such schemes as were recognized as standard because of their successful operation.

A second request for information was sent out February 24, 1920, in order to obtain an authentic record of schemes which are being, or have been, tried out and proved successful or abandoned as worthless.

In pursuance of the program outlined in the report of the Committee last year, the members to whom the six Geographic Sections of the United States and Canada were assigned have submitted to the Chairman answers to the request for information from practically all the operating companies to whom these requests were sent. Much interest was manifested by the various companies in the work of the sub-committee and, while some of the replies were delayed because of the pressure of other work, it may be said that, in general, they responded very promptly.

In replying to this request practically every company has given a description of all relay schemes which it has used, both standardized and otherwise. In many instances the information on the standard schemes is much more complete than that which was given in the reply to the first questionnaire, thus adding to the completeness of the sub-committee files and further substantiating the conclusions given in the previous report.

On account of the very large volume of material contained in these reports the sub-committee has not yet been able to coordinate it into the form of a report. A great amount of classification and compilation will be necessary in order to reduce the information to a report of practical value, and the sub-committee is now engaged in this task. It is planned to present this report in a meeting of the Institute some time next winter.

In addition to the various schemes described in the June 1919 Institute PROCEEDINGS several companies have reported the successful use of other schemes and not a few reported certain schemes still on trial or tried out and abandoned. It is not possible to describe these in this brief resume, though casual mention of two or three of those now in successful operation will be of interest and will serve as an indication of the general trend in protective work.

A new pilot wire scheme has been used very successfully over a period of approximately three years by one large company. This company's system has become so complicated that considerable difficulty was experienced in determining relay settings and in securing selective action of relays.

The new pilot wire scheme was therefore developed in order to reduce the number of relays requiring progressive settings and to simplify and reduce the settings on other relays where this could not be used. It is known by its originator as the Balanced Differential Relay System, and depends for its operation upon an unbalance of currents in the differentially wound relay coils. Such unbalance in the case of a fault on the line results from partial or complete opposition of e. m. fs. on the pilot circuit. On a through fault the e. m. fs. are additive and equal currents flow in the relay coils, but in opposite directions, so as to neutralize. Under normal conditions no current flows through the relays or in the pilot circuit.

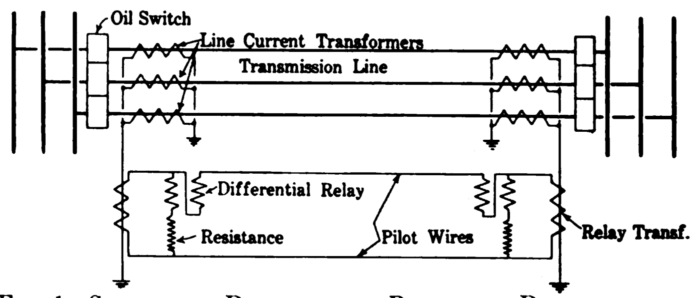

FIG. 1—SCHEMATIC DIAGRAM OF BALANCED DIFFERENTIAL RELAY SYSTEM

This scheme is illustrated in Fig. 1 and as may be seen, only two pilot wires are necessary. It is very simple, and on short lines compares favorably in cost with other standard installations. The cost will increase, however, as the line becomes longer because of the necessity of pilot wires.

In case this scheme is used on ungrounded systems where a ground is not involved in the fault it will be found necessary to use a modification employing three pilot wires. This is not illustrated.

Another company reports the successful use of a modification of the balanced or cross-connected relay scheme in which an additional double-contact differential current relay is used. This scheme is applicable to parallel lines, the lines being paired off and balanced against each other. In the case of three lines the current relays on the third line are given special settings. The differential relays are not used to trip the circuit breakers but to reduce the time settings of the relays on the faulty line to approximately one-half that of the relays on the other line. Thus the faulty line of the pair is selected and the other line is left with adequate relay protection. Advantage for this scheme, over the instantaneous balanced scheme, is claimed in that the circuit breaker is not called upon to interrupt the initial rush of current. If it is desired however, the differential relay can be connected to trip

the circuit breaker direct. A diagram of the connections used is shown in Fig. 2.

The cost of this scheme is the same as that of a standard installation except for the additional cost of the differential relay, which is practically the same as that of the standard induction type current relay.

One very interesting installation of selective ground

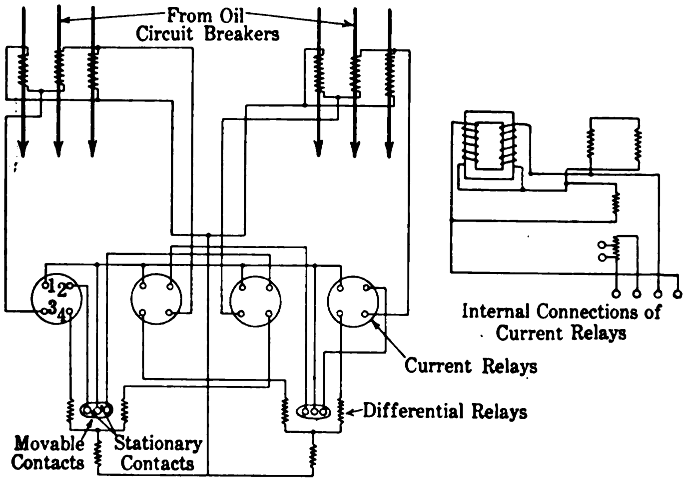

Fig. 2—Schematic Diagram Showing Differential Relays

relays is reported. All operations up to the date of the report had been successful but the time of service was not considered sufficient to prove definitely its value. The scheme was installed with the expectation

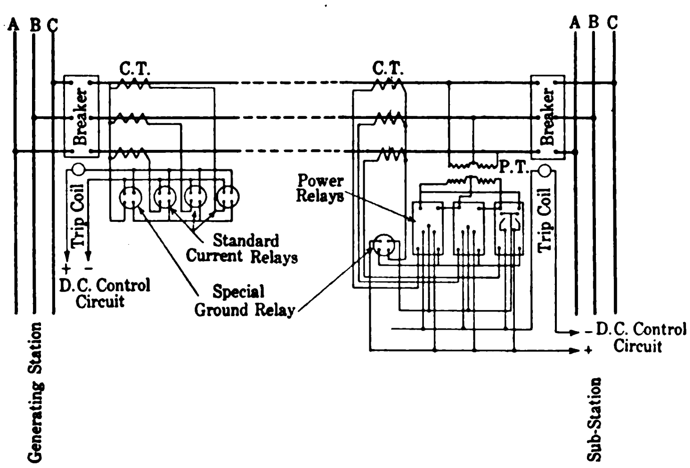

Fig. 3—Schematic Diagram Showing Use of Ground Relay

that faults of slow development to ground would be cleared at an earlier stage than is possible with phase relays, thus preventing the trouble from being communicated to nearby lines and preventing the system from being subjected to severe shock.

A special relay wound for low operating current and having low energy requirements is inserted in the current transformer neutral lead on standard current and power relay installations. When used with current relays this ground relay trips the circuit breaker direct, while with power relays at the substation end it is arranged to short-circuit the over-current phase relay contacts, thus leaving the power relay to discriminate as to direction of power flow. The principle of operation is obvious since current will flow in the ground relay only upon the occurrence of a ground. Therefore, in the case of phase to phase short circuits the operation of the phase relays is not interfered with. This may be clearly seen by referring to Fig. 3.

The cost of this scheme exceeds that of the standard installation only by the additional cost of the ground relay which is practically the same as that of the standard type current relay.

The above developments would indicate that the general trend is toward the selection of defective lines by means of the fault or trouble current rather than by relying altogether on the use of progressive time settings and current settings on the basis of the total current. As systems grow larger and more complicated progressive settings necessitate maximum time intervals which are so high as to be impracticable and the need for adequate schemes which do not require progressive settings has become a necessity as well as a convenience. While no scheme has as yet been developed which can be universally applied and which will obviate the necessity of progressive settings, the manufacturing and operating engineers are to be commended for their efforts toward this end. Results which have recently been obtained give promise of a closer approach to the ideal means of protection.

It is the aim of the sub-committee on Schemes of Relay Protection to preserve an accurate record of the developments and operations of the various protective schemes, which records will be available to the operating and manufacturing companies under the Committee rules. It is to be hoped that the service of this sub-committee will play some part in preventing duplication of effort among engineers and foster a gradual tendency toward the standardization of protective relay schemes and devices.

D. W. Roper, *Chairman.*

IRON AND STEEL INDUSTRY COMMITTEE

To the Board of Directors:

During the past year, the important part played by electricity in the Iron and Steel Industry has in no wise diminished, although the extent of the growth of electrification has been relatively small as compared with recent years, due to the almost complete cessation of expansion in the industry, beginning in the latter part of 1920.

Periods of business depression, with the coincident demand for low production costs, invariably bring into prominence the wasteful and imperfect producing element of each plant, and the present period is no exception. Furthermore, the present necessity for finding ways and means of meeting low-priced competition in foreign markets adds emphasis to the searching out of inefficient units. As heretofore, the more

general application of electric power is usually an important factor in the strengthening of the weak links, so that at this time, a large amount of electrical installation, particularly in the line of replacing steam engines in the drive of main rolls, is recognized as essential and is only waiting upon the devising of means of financing.

Much progress has been made in the most recent installations of reversing mill drives and of adjustable-speed equipments for the lighter finishing mills. Control equipment of all kinds shows marked tendencies toward simplification, although at the same time making possible considerable reduction in the human element in the industry.

In common with all industry, the iron and steel plants of many parts of the country will, on resumption, be confronted with the power problem and much attention is being directed toward the development of dependable low cost sources of electrical energy. Again, in steel plants of size, the transportation of the raw and semi-finished materials within the plant limits is responsible for an important percentage of the total production cost and investigations are being directed to the possibilities of the reduction of this item by yard electrification.

Your Committee cooperated in every possible way with the Pittsburgh Section and Meeting and Papers Committee of the Institute in arranging for the Institute Meeting in Pittsburgh on April 16th in joint session with the Association of Iron and Steel Electrical Engineers. One of the papers was prepared by D. M. Petty, a member of the Committee, and other members contributed discussion. The meeting was a very successful one and served to continue the close and harmonious relations so desirable between these two national societies.

William F. James, *Chairman.*

TRANSMISSION AND DISTRIBUTION COMMITTEE

To the Board of Directors:

The Cable Research sub-committee appointed jointly by your Committee and the Underground Systems Committee of the National Electric Light Association continued its work during the year.

As the standard specification for paper-insulated lead-covered cables, completed by the sub-committee last year, met with such general favor, it was suggested that the sub-committee prepare similar standard specifications for rubber and varnished cambric insulated cables.

For the reason that considerable work along these lines had already been done by committees of other technical organizations but particularly because the Institute had recently joined the American Engineering Standards Committee it appeared that the entire subject of cable specifications should be brought before that body.

A conference was called in New York on February 2nd, 1921 by the American Engineering Standards Committee and after a thorough discussion of the many considerations involved it was unanimously decided that the unification of cable specifications for wires and cables for other than telephone and telegraph use should be undertaken under one general plan covering substantially all the more important uses. This work is now being carried out under the auspices and in accordance with the rules of procedure of the American Engineering Standards Committee.

In the matter of standardization of cable ratings, some work has been done by the Cable Research sub-committee and further investigations are in progress. Similar work is under way in England under the supervision of the British Electrical and Allied Industries Research Association.

The published report of that Association as well as the investigation so far conducted by the Cable Research sub-committee show very clearly a lack of agreement as to the maximum permissible operating temperature of paper insulated cables.

Until an agreement can be reached on this very important point it will be impossible to arrive at any definite conclusions regarding cable ratings. It may be possible, however, to prepare a tentative rating for cables of various sizes and voltages to show the permissible current for various maximum temperatures and under definite physical conditions, leaving it to each user of cable to determine, for the present, the maximum permissible temperature for his own cables.

At the Midwinter Convention of the Institute, one session under the auspices of the sub-committee on Wires and Cables, was devoted to the discussion of cable ratings and papers were presented by a number of manufacturers and users of paper-insulated, lead-covered cables.

A number of those participating in the discussion expressed the opinion that the maximum limit of 85 deg. cent. is too conservative for low-voltage cables in which the dielectric losses are small and several believed that the limit should be placed at 105 deg. cent. which is the limit for fibrous insulation in electrical apparatus.

It is expected that steps will be taken during the coming year to initiate investigations which will result in a definite determination of this maximum permissible temperature.

Tendencies in Overhead Transmission and Distribution Practise

Transmission. The present tendency in transmitting electrical energy is decidedly toward the use of increased voltages. This is particularly so in considering transmission problems, which problems are now involving the transfer of larger blocks of power over longer distances than were formerly considered practical and economical.

The interconnecting of various load centers to take advantage of diversity in demand is receiving the careful attention of transmission engineers. Transmission lines operated at 150 kilovolts have been in service for a number of years and materially higher voltages are now considered. At least one line, that of the Southern California Edison Company, is under construction for 220 kilovolts. This line is being built in connection with the Big Creek No. 8 hydroelectric development and will form part of a system for transmitting over a distance of 240 miles, about 750,000 h. p. at 220 kilovolts.

It would appear that the limit in transmission voltage will be governed by the successful development of conversion and switching apparatus to control the large amount of energy requiring such voltages. Practically all the earlier transmission lines were constructed on steel supports. There is a tendency today, however, particularly in the West, to construct such lines on wood supports, using spans up to six hundred feet in length.

The quality of insulators now available is apparently much better than that obtainable prior to about 1915. This applies particularly to suspension insulators, and while suspension insulator practise since 1915 has shown improvement in performance under operating conditions, a sufficient length of time has not elapsed as yet, to measure this improvement. The design of pin insulators has undergone a decided change in recent years; as now designed they are more substantial, and their performance has been considerably improved. The tendency today apparently acknowledges the greater necessity for a more careful selection, dependent on load characteristics, climatic conditions and also a higher electric factor of safety than was former practise. Every effort is being made to increase the margin of puncture over flashover voltage. Arcing horns and similar devices are coming into use, so designed that no part of the insulator or conductor will be damaged during flashover, by the heat of the arc.

The effect of heat cycles, cement expansion, and similar characteristic changes in insulators is being studied in order to reduce to a minimum the so-called insulator depreciation. The results obtained thus far cannot be said to warrant any radical change in the physical design.

Apparently, overhead ground wires for lightning protection are being discontinued in many locations except where such wires have been installed to provide additional stability to the line structures, dependence being placed entirely upon the successful performance of the lightning arresters connected to the line.

The practise of carrying on maintenance and repair work on live transmission lines seems to be gaining in favor, special tools and equipment having been designed for changing insulators, carrying on new construction work and making repairs to both the line and its accessory equipment.

Aerial cable operated at voltages up to 26,000 has been installed through thickly settled communities for transmission purposes. This field seems to provide a possible solution to many problems involving the transmission of large blocks of power, through thickly settled territories, which heretofore has been considered possible only by the installation of an underground system.

Distribution. It would seem that no great change is to be expected in the 2200-4000 volt distribution system, so generally used at the present time. To provide for the rapidly increasing demand for electric service, additional substations are being installed, fed by aerial or underground transmission lines at relatively high voltage, from which substations the lower voltage primary circuits radiate.

The diverse character of the loads now being connected is resulting in the practise of dividing distribution systems into distinctively lighting and power service. It is common practise to construct power circuits at a higher primary voltage than the lighting circuits, connecting to the power circuit large motor loads, electric furnaces, welders, and similar types of utilization equipment; and as such equipment is usually of low power factor, special attention is being given to the development of power factor corrective apparatus in order that the entire capacity of such feeders will be available for distribution purposes.

The banking of transformers where the loads are congested, is now being generally considered, it having been demonstrated by a number of installations, that not only the power loss is materially reduced but the investment cost in transformers, copper and other similar items is materially lowered.

The greatly increased loads now commonly distributed, together with the large capacity of many of the systems is necessitating the complete redesign of much of the line switching and protective apparatus.

Probably the most recent distribution problem is the connecting of the loads in the more scattered or rural districts. The development of the so-called "farm lines" to reach this class of service has been very rapid. Electric service is a necessity to the modern farming community and its connection is resulting in the development of distribution circuits of 13,000 volts, more or less, constructed in a substantial manner but without the refinements of city construction. Such service is becoming available in practically all sections of the country. Extensions twenty-five to thirty miles in length feeding from fifteen to twenty customers are becoming common.

Tendencies in Underground Cable Practise

Higher-Voltage Cables. Better knowledge of the characteristics of impregnated paper insulation has made it possible to manufacture cables for operation at voltages much in excess of those formerly standard.

Three-conductor paper-insulated cables are now

being manufactured to operate at 33,000 volts whereas in the past 25,000 has been the maximum voltage commonly used with this class of cable.

During the year one of the largest central station companies ordered cable to be operated at a voltage higher than any heretofore used in this country. In Chicago there will be installed during the year about thirty miles of three-conductor cable intended for a normal working pressure of 33,000 volts. This cable will have sector shaped conductors each of 350,000 cir. mils, with 19/64 in. insulation around each conductor and 7/64 in. outer belt; the thickness of the lead will be 9/64 in. The over-all diameter will be about 2.95 inches, so that it can be installed in a 3½ inch duct. This cable will be used for two tie lines between a new generating station and one of the older generating stations which is near to the center of distribution.

It is also possible by reverting to single-conductor design to manufacture cable for operation on circuits rated at 60,000 or possibly 100,000 volts. This increase in voltage at which underground cables can be operated is an important advance, as high voltages have long been used on open wire circuits and in many cases the inability to construct cable of corresponding voltages has been a serious disadvantage. There will be many instances where high-voltage cables can be used to advantage in eliminating the necessity of extra transformations.

It is understood that the 60,000-volt single-phase feeders of the St. Gothard line in Switzerland has recently been placed in service, 30,000 volts being impressed on each single conductor cable.

Larger Cable Sizes. The necessity for using larger sizes of conductors has further increased the demand for sector cables on account of their smaller over-all diameter.

Two-conductor *D*-shape sector cables of 1,000,000-cir. mil and 1,500,000-cir. mil cross section are being used to a large extent on Edison d-c. three-wire circuits. The principal reasons for using this type, instead of the concentric type formerly employed, are the greater ease in splicing and the better balance of the resistance between the two sides of the three wire system.

Dielectric Losses. The subject of dielectric losses in cables is recognized as being important, but on account of the material reduction in the dielectric losses in cables as at present manufactured, the subject is not so often overstressed as was the case when the matter was first generally discussed. It should also be noted that cable properties are largely interdependent and that undue development of one characteristic may result in the sacrifice of some other equally important feature.

There is now available, cable which will not have more than 0.75 watt dielectric loss per foot of cable when operating at the maximum temperature allowed by the Institute Standards. Cables having dielectric losses within the limits shown in Fig. 1 will be found satisfactory.

Hochstadter Cable. Hochstadter Type *H* triplex cable in which the insulation of each single conductor is covered with an electrically conducting foil (usually of copper) and the three individual conductors assembled without any belt insulation, is in successful operation at high voltage.

Two companies have recently ordered three-conductor cable of the Hochstadter type for operation at about 25,000 volts. One of the companies ordered only sufficient cable for a portion of the line and the remaining cable was of the ordinary type with the insulation divided between the conductor and the outer belt. In the other case the entire order was for cable of the Hochstadter type but the manufacturer, at the request of the Cable Research sub-committee, made up a short length of the usual type three-conductor cable for a comparative test, this cable being made of the same materials and manufactured at the same time as the Hochstadter cable.

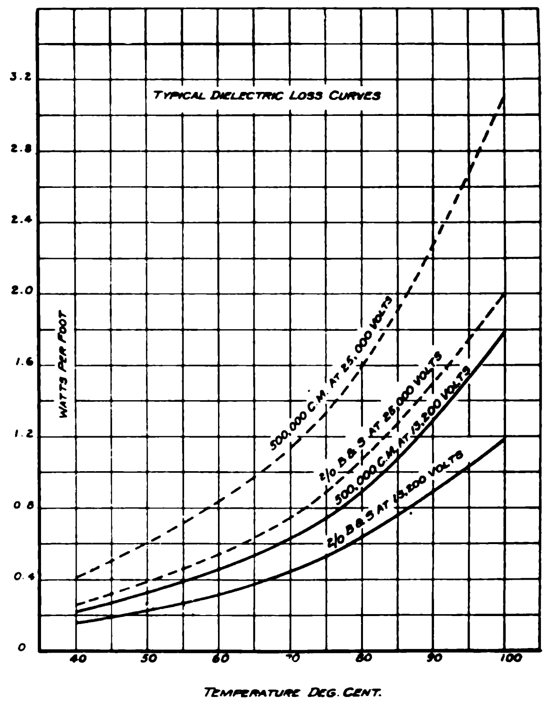

Fig. 1

As a result, the Committee has available the two sizes of Hochstadter cable to compare with the same sizes of cable insulated in the usual manner and has arranged for comparative tests of the merits of the two types of cable. A number of the larger operating companies, and the National Electric Light Association have contributed to the fund necessary for making these special investigations, the result of which should be available during the coming year.

Crystallization of Lead Sheath. Though the method of applying the lead sheath to underground cables has

changed but little in many years, there has recently come to notice a number of cases where the lead sheath has crystallized. This is not a new condition but in the past it has been comparatively infrequent. There have been a number of cases where cable shipped for a considerable distance showed signs of defective lead on arrival at its destination while other instances of similar character have been noted in the sheath of cables that were subjected to vibration after installation.

There is evidence of a direct relation between vibration and crystallization of the lead sheath, but it has not been definitely determined whether crystallization is hastened by improper methods in manufacture. It has been suggested that in many cases crystallization has been caused by localized impurities, or by the lead having become too cold in the die.

Power Cable Testing. Power cable testing practise is at present divided into four important branches:

1. Factory research and routine tests.
2. Independent laboratory tests.
3. Factory inspection and acceptance tests.
4. Field or installed tests.

1—*Factory Research and Routine Tests.* Factory research and routine has in recent years been stimulated by the demands of users for cable of higher quality, suitable for operation at increased loads, higher temperatures and higher voltages. Research work by progressive manufacturers has resulted in greatly improved product in all respects. It has also indicated most forcibly the need of improved routine tests in order to check materials and processes so that uniform high quality may be insured at all stages of manufacture. If the routine factory tests are properly planned and carried out during manufacture a consistently uniform product may be turned out, which need be checked only occasionally by special laboratory tests on the finished product. It is obvious therefore that the selection of materials and their handling during manufacture are the most important features of cable manufacture.

2—*Independent Laboratory Tests.* Independent laboratory tests have been carried out, at the request of both consumers and manufacturers. The results have been of great value from the standpoint of all interests for the following reasons:

a. Standard methods of testing have been formulated.

b. Advance information has been secured by consumers and manufacturers alike, which has in some cases resulted in manufacturers realizing the desirability of having their own laboratories equipped for test and research of similar nature.

c. General information which has been given out by such laboratories has shown a great lack of uniformity in the product of some cable manufacturers. This non-uniformity appears to be due to lack of knowledge as to how the component parts of a cable must be handled and tested during manufacturing processes.

3—*Factory Inspection and Acceptance Tests.* It is the practise of many users of power cables to carry out inspection at the factory before cables are accepted for shipment. Some also inspect during the process of manufacture as far as permissible without unfair inquiry into manufacturing secrets. This practise, which appears to be growing rapidly, keeps the manufacturer on the alert because his ultimate profit depends upon the acceptability of his product with a minimum number of rejections.

4—*Field or Installed Tests.* Many power cable users make regular tests after installations to detect injury during installation, and inadequate or faulty jointing. These tests vary from insulation resistance tests only, to complete high potential, insulation resistance, conductor resistance and capacitance tests.

In some cases it appears that unnecessarily severe tests are made which may result in injury to the cable. The test of service is undoubtedly the best of all. Any test which will detect incipient faults due to handling or installation is all that is reasonably required in addition to the factory tests and the test of time.

The safe loading of cables requires a knowledge of the characteristics of the cable location. Test to determine their characteristics are not, strictly speaking, cable tests, but they are of equal if not greater importance. This subject is being studied in this country as well as abroad and some preliminary results have been published in the technical press.

General. The Committee has called attention in previous reports to the reduction in dielectric loss at relatively high temperatures. Routine factory tests inaugurated by some manufacturers have made it possible to predict with accuracy the dielectric losses in the finished cable, which constitutes an important step in the production of cables uniform in this respect. One of the most important results not inconsistent with uniformly low dielectric losses is uniformity of dielectric strength, which has been noted to a considerable extent. The Committee does not think it proper, however, to refer more specifically to routine tests as they are largely the result of factory research.

There appears to be little of importance to report with respect to new methods of testing cables with high voltage, either in the factory of field, with the possible exception of the use of d-c. devices such as the Kenotron. This device appears to have possibilities of great importance and, as used experimentally by at least two utility companies, appears to fill a long-felt want for a light and portable apparatus for cable testing, and requires but a very small amount of power or capacity for its operation.

Attention is called to the possibility of paper-insulated cables breaking down under high-voltage tests but followed by immediate rehealing of the puncture.

This rehealing is usually temporary but may persist long enough to deceive in a test of stated duration. It is therefore essential that these "spits" be recognized and the test repeated until they have been eliminated.

The practise of testing faulty cables for fault locations has undergone no material change, the devices used being divided into two principal classes, one depending upon the principle of bridging, the other upon the exploring coil with signaling current.

Various mechanical tests are made on cables and cable dielectrics with which most engineers are familiar. One of particular interest is the so-called bending test on paper-insulated power cables. This test is carried out for the purpose of determining the likelihood of a cable being injured by handling during manufacture or installation.

Protection of Cable Systems. The increasing frequency of trouble on low-voltage (less than 550-volt) systems and the consequent danger of communication to other circuits has necessitated a great deal of attention being given to the problem of segregating the circuit on which the trouble originates.

On account of the probable resistance of the fault being sufficiently high to limit the flow of current, at this low voltage, to a value possibly not more than the normal load, it is impossible to get the desired protection by the use of fuses. For this reason some companies have omitted the fuse, while one company fearing an extended burn-out of this class of cables has provided each feeder conductor with a remote-controlled circuit breaker at the service end of the feeder designed to open when the feeder is in trouble.

These circuit breakers do not open from overload but have a trip coil that is connected to a pressure wire in such a way that, if the pressure wire comes in contact with either the lead sheath or the main conductor, the coil will become energized and open the circuit breaker. There is also provision at the station whereby the operator can, by closing a small switch, put current on the pressure wire to trip the switch.

With higher-voltage distribution cables, around 3000 volts for example, there is no difficulty in providing fuses that will carry normal load and blow under short circuit; but in this class of service the problem is to provide a fuse which will successfully open the circuit. For this reason a number of engineers recommend against the use of fuses on underground systems of this voltage.

When we consider still higher voltages of the order of those used for transmission, no attempt is made to use fuses underground. However, the majority of underground troubles originate on this class of cables and it is extremely important that every precaution be taken to prevent trouble starting in one of these cables from communicating to others. For accomplishing this, ducts should be separated by an adequate wall of fire resisting material, such as is obtained by laying fiber tubes in concrete so that the ducts will be separated by a continuous wall of concrete about one inch thick, except near the manholes where the separation should be increased to give a maximum separation at the end of the ducts. This extra separation at the edge of the manholes is advisable on account of the danger of communication of trouble from one cable to another at this point where the protection to the cable is apt to be least. The importance of protecting cables in manholes will be evident when it is considered that more than one-third of the failures in the higher-voltage cables occur in splices alone and a large percentage of the remaining failures also occur in the manholes.

Concrete continues to be the most popular form of protection in the manholes. It is not only a good protector against fire but it is also a better conductor of heat than other forms of protection. Owing to the effect of heat in decreasing the resistance of the insulation of high-voltage cables, it is extremely important, especially with cables constructed a few years ago, to avoid excessive temperatures in the duct line. This applies not only to heat dissipated by the cables themselves, but also to that produced by other sources, such as steam pipes and exhaust steam. There have been many instances during the last few years of serious troubles due to high temperatures produced by steam. Where it has been a case of exhaust steam or a local steam pipe it has been comparatively easy to overcome the trouble by changes in either the duct line or the point of exhaust, but where the heat has been experienced at many points due to an extensive steam heating system, changes that would be necessary to remedy the trouble have been too expensive to undertake.

Review of Papers Submitted During the Year

Insulators. In the May, 1920 issue of the Journal W. D. A. Peaslee contributed an article on *High-Tension Insulator Porcelain.*

This paper reviews the progress made in the ceramic field in the solution of the insulator problem. Procelain used in the manufacture of high-tension insulators must meet certain requirements as to mechanical strength, ability to resist sudden changes in temperature, porosity, homogeneity, and temperature coefficient of resistivity. The author gives a brief discussion on each of these requirements and the progress that has been made in the development of a suitable porcelain. A brief discussion is also given regarding the possibility of the deterioration of seemingly perfect porcelain being intimately connected with the Piezo electric qualities of quartz crystals.

In the June, 1920, issue of the Journal the same author discusses *Factors Controlling the Design and Selection of Suspension Insulators.*

Attention is called to the factors entering into the design and operating behavior of suspension insulators and the problems to be solved in designing a suspension insulator to overcome the objectionable features shown by experience to affect seriously the operation of the insulators in service. Factors to be taken into consideration in the selection of suspension insulators for a given condition are given and a brief discussion of the general trend of future developments is presented.

F. W. Peek, Jr., presented an article in the July 1920, Journal reviewing the duties of the line insulator at voltages above 100 kv. and comparing them with the duties imposed by the lower voltages in order to predict the reliability of future high-voltage

lines as compared with those at present in operation and pointing out what changes, if any, are necessary in present practise. While unimportant at the lower voltages, the uneven division of voltage on the different units of a suspension insulator becomes of increasing importance as the voltage is increased. Quite complete data are given on the phase of the investigation dealing with voltage distribution and the successful correction of the uneven voltage distribution by means of an antenna shield from the line. The author believes that with the very high voltages at present being considered, insulator troubles will probably be less frequent than with present voltages.

Operating Performance of Insulators on a 45,000 Volt System by H. B. Vincent in included in the January, 1921, JOURNAL.

This paper presents a method for the recording of insulator performance and shows how such a record enables one to know what service the insulators are giving and what one may expect provided the records have been kept over a sufficient period of time. The data presented refers entirely to pin type insulators and has been gathered from actual records kept by a power company. There is included an analysis of the data obtained from this company's report showing the performance of insulators on the various lines from 1914 to 1919 inclusive.

H. J. Ryan and H. H. Henline contributed an article appearing in the July, 1920, JOURNAL dealing with the quantitative relations which exist between the maximum and average voltage unit-duties in line suspension insulators made up of units in common use. The results obtained from a number of tests conducted by the authors to determine these relations on insulators of single and double strings with and without static shields are discussed in detail. From their investigations the authors believe that suspension insulator unit in common use can be satisfactorily employed for the makeup of insulators for 250-kv. lines.

Surface Leakage as a Factor in Insulator Design by T. M. Feder is discussed in the September, 1920, JOURNAL. The author calls attention to the various factors influencing surface resistance and the different methods by which this resistance may be increased. It is shown that the most economical way of decreasing the leakage is the addition of properly proportioned corrugations on the underside of the flange or skirt. Typical computations are given, showing the approximate increase in resistance to be expected when corrugations are added.

Overhead Transmission and Distribution. The 150,000-Volt Transmission Line of the Knoxville Power Company is described by Theodore Varney in the June, 1920, JOURNAL. The author discusses problems encountered in the design and construction of this line and the solution of these problems are described.

The conductor is of aluminum reinforced with steel and the longest span is 5010 feet long, which the author states is the longest single-conductor span in the world at the present time. A detailed description of both the standard and long-span conductors is given toegther with a summary of the points covered by the specifications drawn for the purchase of the standard suspension and anchor insulator units.

The July, 1920, JOURNAL includes an article prepared by D. M. Jones on *Power Factor Correction on Distribution Systems.*

After a review of the causes and disadvantages of low power factor, the writer discusses various methods of eliminating this condition. The methods provide for the use of the unity power factor synchronous motor, the phase modifier, the overexcited synchronous motor, the synchronous condenser, and the static condenser. The advantages, disadvantages and comparative costs of each type of apparatus are discussed.

P. O. Reyneau and Howard P. Seelye prepared an article which appeared in the October, 1920, JOURNAL on the *Economic Study of Secondary Distribution.*

This paper analyzes and evaluates the factors in the design of the secondary system which lend themselves to such definite analysis and presents the results as aids in the determination of the most economical design for a system. The derivation and application of equations and curves used for the determination of the most economical voltage drop, transformer spacing, transformer size and wire size under theoretical conditions are presented and discussed. Curves for practical conditions are then worked out for use of the designing engineer.

Cables. R. W. Atkinson prepared an article which appeared in the September 1920, issue of the JOURNAL on *The Current Carrying Capacity of Lead Covered Cables.*

After discussing the temperature rise in cables and their surroundings the author describes a method of determining the current-carrying capacity of cables based upon their temperature rise. Data are given whereby the current-carrying capacity of lead-covered cables can be calculated on the basis of thermal limitations. Carrying capacity as limited by voltage drop or economical considerations is not considered. The article shows how further data can be applied as these are determined.

An appendix contains some numerical examples illustrating the use of the data and in addition a chart by which it is possible to determine graphically, for given conditions, the carrying capacity of three-conductor paper and varnished-cloth cables installed in conduits.

C. W. Davis and D. M. Simons presented an article on *Maximum Allowable Working Voltages in Cables* appearing in the January, 1921, issue of the JOURNAL

This paper discusses methods of calculating stresses in triplex cables and gives examples of calculations made. Tables are given for determining maximum voltage stress in single triplex and type *H* cables. From calculated stresses the authors obtain a solution for the size of conductor which will produce a minimum stress for a given core diameter. The determination of the maximum possible operating voltages for given limits of stress and outside diameter is then described. From the limits worked out in this article it is the conclusions of the authors that for the high-voltage cables of the future the ordinary three-core form cable will be used as heretofore up to 30,000 volts, type *H* cable up to 50,000 volts, and three single-conductor cables having conductors made with a hollow fiber core for 50,000 volts and above.

At the mid-winter convention in February, 1921, James A. Cook presented a paper dealing with *Measurement of Relative Eddy Current Losses in Stranded Cables* describing a method which will insure accurate measurements of eddy current losses in stranded copper cables on a comparative basis. Results of tests are shown both for the measurements and the reduction of eddy current losses.

CONVENTION PAPERS

The following papers have been submitted and accepted for presentation at the Annual Convention at Salt Lake City:

Long Distance Transmission of Electric Energy by L. E. Imlay.

Voltage Regulation and Insulation for Large Power, Long-Distance Transmission Systems, by Frank G. Baum.

Voltage and Power Factor Control of 66,000-Volt Transmission Lines Connecting Two Generating Stations, by Raymond Bailey.

A Solution of the Porcelain Insulator Problem, by E. E. F. Creighton and F. L. Hunt.

Modern Production of Suspension Insulators, by Edwin H. Fritz and George I. Gilchrest.

Voltage and Current Harmonics Caused by Corona, by F. W. Peek, Jr.,

Transformers For Interconnecting High-Voltage Transmission Systems or For Feeding Synchronous Condensers from A Tertiary Winding, by J. F. Peters and M. E. Skinner.

Some Transmission Line Tests, by W. W. Lewis.

The Operation of Large Interconnected Systems, by L. L. Elden.

E. B. MEYER, *Chairman.*

LIGHTING AND ILLUMINATION COMMITTEE

To the Board of Directors:

The Lighting and Illumination Committee considers that along with the other Technical Committees, it can render a special service to the Institute, by securing papers which relate to subjects within the scope of the Committee and which will be of particular interest to the members of the Institute. The three excellent papers on street lighting distribution presented before the Chicago meeting last year illustrate this point. Following out this general thought, the Committee held a meeting early in the year for the purpose of considering what activities could be undertaken during the current year.

The results of this meeting of the Committee may be summarized as follows:

1. That it would be of value to members of the Institute for the Committee to start the accumulation of data relating to productive intensities in industrial plants, that is, to the question of intensities of illumination in the industries best suited to effective production. This data could well cover the question from the standpoints of the relations of illumination to factory production, to accidents and to reduced spoilage. The Committee felt that it might not be practical to attempt to secure papers on this subject this year because of the incomplete nature of studies which have been and are being made along this line, but it is hoped that in the near future papers may be secured on several particular aspects of the problem such as those relating to opthalmology, psychology, physiology, accident prevention, scientific management and production records.

2. The Committee felt further that it may be possible to secure a paper at some time in the near future dealing with glassware for lighting auxiliaries, such as that used with street and commercial lamps. A paper on this subject did not materialize during the current year but the Committee feels that a general summary of the glassware situation would be of considerable practical value.

Although neither of the foregoing plans of the Committee has taken definite form during the year, it is believed that the formulation of these suggestions has, in itself, been an item of progress and that it may lead ultimately to certain very valuable papers.

In addition to an effort to gather papers, the Committee feels that it may also render a service of value to the Institute by carrying out the intent of the resolution of the Board of Directors of May 11, 1921 through the preparation, as part of the annual report, of a brief summary of progress of the art in the lighting and illumination field. In the present report, reference is made to some of the more important features of the year's progress without any effort to make it complete in detail. Very full notes on the detailed progress and developments in this field are published each year as a Progress Report by the Illuminating Engineering Society. The following notes cover some of the more interesting developments which have been noted by the Committee and by the technical press during the current Institute year:

DEVELOPMENTS IN THE LIGHTING FIELD

Use of Incandescent Lamps. It is interesting to note at the outset that the estimated sale of incandescent lamps in 1915 amounted roughly to about 110,000,000 whereas in 1920 it was estimated that 230,000,000 were sold. These figures indicate that the lamp business has practically doubled in the five year interval from 1915 to 1920. One of the large lamp manufacturers estimates that of the total in 1920 about 215,000,000 or about 92 per cent were tungsten filament lamps and about 16,000,000 were carbon filament lamps. This marked increase in the sale of incandescent electric lamps may be taken in a measure to represent fairly the growing use of electric lighting throughout the United States and it is of considerable interest to note here that the tungsten filament type has now almost entirely superseded the older carbon filament lamp.

The popular idea that the use of arc lamps is decreasing does not seem entirely consistent with the fact that the sale of luminous arc lamps during 1920 indicated an increase of more than 50 per cent over that of 1919.

Lighting in the Industries. The past year has evidenced marked attention on the part of factory managers to the effects of good lighting upon plant production, to the reduction of accidents and to minimizing spoilage. In one large industry an extended study was made to determine whether materially higher intensities of illumination than were formerly used, are warranted on the basis of improved production. These tests have not demonstrated fully just where practical intensity limits should be set for given classes of work nor what relations exist between good lighting and production, but the opinion is quite prevalent that higher intensities promote better workmanship and hence present practise tends towards the design of lighting systems with more liberal intensity levels than formerly.

The relation of poor lighting to accidents has received careful attention. It has been stated that during the 19 months the United States was in the last war, 56,000 American soldiers were killed in Europe, whereas during the same period 236,000 men, women and children were accidentally killed in this country. Of the enormous number of industrial accidents it has been fairly well established that possibly from fifteen to twenty per cent may be chargeable either directly or indirectly to poor lighting. This conclusion has been an item of importance in the work of regulating factory lighting by the State Departments.

The effect of light colored walls and ceilings on the

illumination resulting from lighting systems is well known to lighting men but not always appreciated as fully as it should be by plant operators. One of the most helpful efforts looking to a better understanding of wall and ceiling colors and their effects on the resulting illumination, has been Bulletin Number 41 issued by the National Lamp Works of the General Electric Company and prepared by Mr. Earl A. Anderson. This excellent bulletin contains sample colors with the corresponding reflection factors and the method of working these reflection factors into the design of a lighting system is clearly indicated.

Lighting Demonstrations. One of the results of the increased interest in high intensities has been the efforts of the lamp manufacturers to educate the industries up to the apparent advantages of better illumination by using the so called demonstration method of illustrating modern practise and its effectiveness. More or less permanent demonstrations have been installed in ten of the larger cities of the country and several others are in various stages of construction. This activity has been fostered by the National Electric Light Association, with the cooperation of local institutions. Similar travelling demonstrations have been conducted by the lamp manufacturers in about one hundred and twelve other cities.

The Pennsylvania Department of Labor and Industry took advantage of the portable demonstrations presented in that state, to educate manufacturers and others in the application of the Industrial Lighting Code.

The demonstrations have also been utilized for the benefit of engineering students; for example, the Edison Lamp Works of General Electric Company recently conducted demonstrations at the University of Pennsyvlania and at Yale University. These demonstrations have doubtless been generally very successful in making an impression concerning the advantages of adequate illumination.

Miscellaneous Items. It has been stated that the foot-candle meter is now being used much more than formerly for the measurement of illumination by the layman through inexpensive means. Several thousands of these instruments have been sold during the past year or so, and the demand for them by the industries, factory inspectors and others, continues to the extent of several hundred per month. An interesting modification of the earlier instrument has been an increase in its range from an upper limit of 25 foot-candles to one of 40 foot-candles so as to make possible the measurement of higher intensities than formerly.

Highway lighting has received considerable attention and a double reflector unit has been developed so as to reduce the waste of light on either side of the roadway. Among the important installations of street lighting which have been completed and put into operation during the past year or so have been those at Los Angeles, Cal., and Saratoga, N. Y.

It is significant and of special interest to central station operators to know that during 1920 nearly 80 per cent of all incandescent electric lamps sold were used on circuits of 110, 115 or 120 volts, whereas in 1913, by contrast, less than 50 per cent of the incandescent lamps sold were used on circuits of these voltages.

C. E. CLEWELL, *Chairman.*

MARINE COMMITTEE

To the Board of Directors:

In presenting the Annual Report of the Marine Committee only the outstanding features of the Committee's work will be dealt with, the vast amount of detail work involved should not be lost sight of however as it was only through the untiring efforts of the various sub-committees that such splendid progress was made.

On referring to the report of the Marine Committee for the season of 1919-1920, the following items are noted; these items represent subjects to be carried over to the following year or new departures recommended for consideration:

1. Rules for the Recommended Practise for Installations on Ship Board.
2. Work of Historical Committee.
3. Fixtures, Fittings, etc. to meet requirements of new rules.
4. Terminal Facilities at Marine Piers.

Eight meetings of the Committee were held. The first meeting convened on September 30th and October 1st, 1920 at Schenectady, New York and was very well attended. The following sub-committees were appointed:

a. American Standards.
b. Applicances.
c. Editing.
d. Propulsion.
e. Auxiliaries.

The Historical Committee was carried over from the previous year.

The year's work of the above sub-committees may be summarized as follows:

The duty of the American Standards sub-committee consists of the taking up with the American Engineering Standards Committee, the question of having the Recommended Practise for Electrical Installations on Ship Board passed by that Committee as a standard for American Practise. This could not be accomplished however, until these rules and recommendations were placed in printed form and circulated.

The duties of the Appliance sub-committee were to formulate a set of Standards covering electrical appliances which would later be incorporated in the Recommended Practise for Electrical Installation on Ship Board. The following is a partial list of appliances intended to be covered by this work:

Conduits and Fittings.
Junction Boxes.
Deck and Bulkhead Stuffing Tubes.
Receptacles, Watertight and Non-Watertight.
Electric Heating Appliances.
Running Tell Tale Panel.
Gaskets and other Watertight Packing Materials.
Pull Boxes.
Fuses.
Plugs, Watertight and Non-Watertight.
Switches, Watertight and Non-Watertight.
Fans.
Telephones.
Bells, Buzzers and other Electrical Signaling Devices.

The Editing sub-committee this year completed the final editing of the Recommended Practise for Electrical Installations on Ship Board and has been retained to handle all comments and proposed changes in regard to these rules which, from time to time, may arise. These changes to be submitted to the main Committee periodically for its action, and if adopted to be made a permanent part of these rules.

The following is given as a resume of the year's work of the Propulsion sub-committee:

It was first decided that Electric Ship Propulsion had not as yet reached a stage of development and continued use that would justify an attempt to draw up a set of Marine Rules or Recommendations for Propulsion Machinery to the same extent as had already been done for other electrical work. With this in view, the work of the Propulsion sub-committee resolved itself into the following:

a. Preparation of papers for an engineering meeting in New York.

b. The drawing up of a set of Rules or Recommendations for the proper preservation and protection of electric propelling apparatus during the time of installation and after being placed in service.

c. The preparation of a history of electric ship propulsion for use of the Historical sub-committee.

In connection with the preparation of papers for an engineering meeting in New York as mentioned above, the following statement may be made:

A joint meeting of the Metropolitan Section of the American Society of Mechanical Engineering and the Marine Committee of the American Institute of Electrical Engineers was held at the Engineering Societies Building, New York, on January 28, 1921. The following papers by members of the Propulsion sub-committee were presented:

Turbine Reduction Gears vs. *Electric Propulsion for Ships*, by Eskil Berg, of the General Electric Company.

Electric Propulsion of Ships, by W. Thau, of the Westinghouse Electric & Manufacturing Company.

Electrical Terminal Facilities, by C. S. McDowell.

The meeting was very largely attended and the papers read contained much useful information.

Recommendations were made by the Propulsion sub-committee for the preservation and protection of propelling machinery during the time of installation and after the apparatus had been placed in service. These recommendations have been completed and preliminarily passed by the Committee but will be carried over until next year before final reading and publication. The historical side of the work of the Propulsion sub-committee received quite considerable attention by that Committee. An extensive list of references of articles which have appeared in publications from the earliest days of electrical installation until about the year of 1911 have been prepared and turned over to the Historical sub-committee.

It was the intention that the work of the sub-committee on Auxiliaries should go along with that of the sub-committee on Electric Propelling Machinery for Engine Room Auxiliaries only. The Deck Machinery and Terminal Handling Apparatus was to be handled exclusively by this Committee. It is contemplated making the Recommendations of this sub-committee, with regard to the above subjects, part of the Recommended Practise for Electric Installations on Ship Board.

A considerable amount of effort has been expended by the Historical sub-committee upon its work during the past year, but owing to the extent of the task and the vast amount of time rquired for other activities of the Committee, it was found impracticable to compile its data complete and in detail for publication at this time. It was the original intention of this subcommittee to complete its work up until the year of 1910 but it was later decided to bring the work as far up to date as possible and then have it supplemented from time to time as developments in the field justified. It will no doubt be possible to turn into the Institute, sometime during the coming year, the work which has already been done by this sub-committee.

From the above it will be noted that the Committee has taken upon itself a great volume of work which cannot be accomplished in one year and probably will extend over a period of several years but considerable work has already been done by this year's Committee as follows:

The final revision and passing of the Recommended Practise for Electrical Installation on Ship Board has been completed and published by the Institute. The writing of papers and reading of the same at the joint meeting of the Metropolitan Section of the American Society of Mechanical Engineering and the Marine Committee of the American Institute of Electrical Engineers in New York. The drawing up of recommended practise for the protection and preservation of propelling machinery, also the vast amount of data on the historical side of electric ship propulsion and electrical installations on ship board. A Joint Meeting has been arranged with the Naval Architects and the Marine Engineers in New York in November at which time two papers will be presented, one on electric propulsion and the other on electric ship auxiliaries.

In concluding this report, I feel that I would be

evading my duty as Chairman of the Committee if I did not congratulate every member of the Marine Committee for his interest, attendance at meetings and general attitude with regard to all subjects that have come up for discussion at the various meetings throughout the year. The Committee as a whole has worked conscientiously and consistently and I believe deserves great credit for the amount of work that it has accomplished.

It is this thought in particular that I would leave with the Marine Committee for the ensuing year, that good work can only be accomplished through good will, consistent application and real cooperation.

ARTHUR PARKER, *Chairman.*

ELECTROPHYSICS COMMITTEE

To the Board of Directors:

ADVANCES IN ELECTROPHYSICS 1920-1921

Progress in physics is, as a rule, gradual and it is generally dfficult to look back over a space of one year and definitely state what will prove to be the most important advances of that period.

The members of this Committee were canvassed regarding the advances during 1920 and 1921, and it was the general opinion that the most striking and what will prove to be the most far reaching work is that of Rutherford on the atomic nucleus. Rutherford has bombarded the atoms of some of the lighter elements with alpha particles and has apparently succeeded in disintegrating them. Nitrogen was one of the elements thus desintegrated. Hydrogen was apparently found in some of the disintegrated atoms.

Work and speculation on the arrangement of the electrons in atoms and molecules seems to be leading to something, and it is hoped that the results will be of great importance.

Among other important work, that on isotopes might be mentioned. The above list is by no means complete but it touches on some of the work that at present stands out.

LECTURES AND PAPERS

It is regretted by this Committee that the electrophysics lecture was not given a place in the Midwinter Convention this year. This lecture in the past has been better attended than any other meeting. The following list of activities of the Institute in different parts of the country during the year is given as indication that electrophysics subjects are appreciated by our membership:

Philadelphia, October, 1920, *The Epoch Making Discoveries of the Years* 1819-1820, by Elihu Thompson. *Oersted's and Ampere's Discoveries,* by M. I. Pupin.

Pacific Coast Convention, July, 1920, *Centennary of the Discoveries of Oersted, Arago and Ampere,* by C. E. Magnusson.

New York, February, 1921, *Wave Transmission,* by M. I. Pupin.

The Electrophysics Committee during the past year has encouraged electrophysics lectures in the Sections. In this connection we were fortunate in assisting the Pittsfield and Schenectady Sections in securing Dr. R. A. Millikin to lecture on the *Twentieth Century's Contribution to our Knowledge of the Atom.* These lectures were very well attended and the discussions indicated a keen interest in the subject by the members.

The following technical electrophysics papers are to be presented at the Annual Convocation:

Electric Strength of Air under Continuous Potentials and as Influenced by Temperature by J. B. Whitehead and F. W. Lee.

Voltage and Current Harmonics Caused by Corona, by F. W. Peek, Jr.

F. W. PEEK, JR., *Chairman.*

HYDROELECTRIC DEVELOPMENT IN LATVIA

The Latvian Government is in possession of various plans for the installation of hydroelectric stations on the Duna (Dvina) River, which, for the most part, were developed by engineers of the Imperial Russian Government prior to the war. These plans constitute a somewhat complete scheme for utilizing the power of the Duna and also for developing the river, through a system of locks and short lateral canals, to make it navigable well into the interior of Russia proper and eventually, through a system of canals connecting with the Dnieper and other Russian rivers, to form an elaborate system of interior water transportation.

The plans foresee the eventual installation of five stations on the Duna River to a distance of approximately 65 miles upstream from Riga.

Of these five projects, the two most seriously discussed for the immediate future are the station at Dahlen, to be utilized for the city of Riga and its industries, and the station of Kokenhusen, to be utilized largely or entirely for railway electrification. Without thorough study it is impossible to say whether the market for electric current and the other relevant considerations would justify large expenditures in such undertakings; but at least the projects are such as to merit very serious consideration. A group of Germans, reported to be the builders of the Keil Canal, has already advanced a proposition to the Latvian government to undertake the installation of the station at Dahlen without special reference to the other four stations; a Belgian group has proposed that it be given the right of installing a station at Dahlen, with a concession for the other four stations to be erected at the company's discretion.—H. L. Groves, in *Commerce Reports.*

SALT LAKE CITY CONVENTION

The combined Annual and Pacific Coast Convention held in Salt Lake City, June 21-24, will go down in Institute history as one of the most successful and enjoyable gatherings of its kind, far exceeding in interest the anticipations of the members and guests in attendance. This was the first time that the A. I. E. E. has staged an annual convention farther west than St. Louis, and the success of this innovation may well lend encouragement to those western members who hope to secure some of the future conventions for the far western states.

The registration of members and guests totaled 426, including 75 ladies. The attendance represented 29 states, Canada, Italy and Spain.

One of the pleasant features of the Convention was the attendance of an Italian delegation of engineers forming a commission on tour of the United States to inspect railway and industrial electrification. The commission was headed by Guido Semenza, E. E., consulting engineer for the Italian government, past president of the Assoziazione Electrotecnica Italiana, and Local Honorary Secretary of the A. I. E. E. for Italy; the other members were Marquis F. Cusani, business manager of the Italian-American Electric Company; Colonel Cesare Scarelli, C. E., head of railway transportation service, general staff, Italian army, and E. Boschetti, secretary; Professor G. C. Ponti, also a member of the commission, was obliged to return to Italy and was therefore unable to be present at the Convention.

The plan of confining the technical sessions to the mornings, which was inaugurated at the White Sulphur Springs Convention last year, has met with general approval and was carried out at the Salt Lake City Convention. These sessions were all well attended, and great interest was manifested in the discussions which related largely to high-voltage, long-distance transmission—a subject of particular importance at this time in view of the projected developments on the western coast.

The afternoons and evenings during the Convention were left open for inspection trips and numerous entertainment features which were provided in abundance by the Convention Committee. The provisions for entertainment and recreation reflected the well-known spirit of Western hospitality and left the busy visitors no time for ennui.

The Convention Committee under the able chairmanship of H. T. Plumb, of Salt Lake City, was indefatigable in its efforts to make the Convention thoroughly enjoyable for everyone in attendance. Each event on the Convention program was in charge of a special sub-committee whose efficient preparatory work resulted in a notable smoothness of operation in carrying out all of the Convention activities. Members of the Committee designated by special badges were constantly on hand to afford any services desired by those in attendance.

Every hospitality was offered the Convention visitors by the local clubs and other organizations. Club privileges were extended by the University Club, the Country Club, the Tennis Club, the Latter Day Saints Gymnasium, the Rotary Club, the Kiwanis Club and by all of the engineering societies in the city. Convention badges were the only credentials necessary to enter any of these clubs and feel at home.

In view of the many courtesies received, the Board of Directors at its meeting during the convention passed the following resolutions:

RESOLVED, that the Board of Directors of the American Institute of Electrical Engineers, representing the members and guests in attendance at the Annual and Pacific Coast Convention at the Hotel Utah, Salt Lake City, Utah, June 21-24, 1921, hereby expresses its hearty appreciation of the excellent arrangements made by the Convention Committee for the comfort and entertainment of the members and guests of the Institute during the Convention.

RESOLVED, that the Board of Directors of the American Institute of Electrical Engineers hereby expresses to

The Salt Lake City Commercial Club
The Salt Lake Country Club
The Latter Day Saints Church
The University Club
The Salt Lake Tennis Club
Utah Chapter, American Institute of Architects
Rocky Mountain Electrical Cooperative League
Electrical Contractors & Dealers Association
Los Angeles and Salt Lake Railroad
Bingham & Garfield Railway Company
Southern Pacific Railway Company
Western Pacific Railway Company
Utah Section, American Society of Civil Engineers
Utah Section, American Institute of Mining & Metallurgical Engineers
Utah Section, American Association of Engineers
Utah Copper Company
Salt Lake, Garfield & Western Railroad Company
Utah Power & Light Company
Utah Society of Engineers
Utah Section, American Society of Mechanical Engineers
Salt Lake Tribune
Salt Lake Telegram
The Deseret News
The New West Magazine
Consolidated Ticket Office
Oregon Short Line Railway Company
Chicago, Burlington & Quincy Railroad Company
Denver & Rio Grande Railway Company

its hearty appreciation of the many courtesies extended by them to the members and guests in attendance at the Annual Convention of the Institute, held in Salt Lake City, June 21-24, 1921.

TUESDAY, JUNE 21

Opening Session. The Convention was called to order at 10 o'clock by Mr. Plumb, chairman of the Convention Committee, who introduced Dean Merrill, of the University of Utah, and chairman of the Utah Section. Dean Merrill welcomed the engineers most heartily and hoped that their time would be so profitably and pleasantly spent and the Convention would be so successful that they would want to come again. Alluding to the electrical developments at Salt Lake City,

Dean Merrill said: "In many of the homes of this city the food is cooked electrically, our homes, our farms, our mines, and mills and interurban railways are all equipped electrically, and the time will soon come within a few years when hundreds of thousands of acres now barren waste near this city will be converted into smiling fields as a result of water pumped by electricity. We believe in electricity—we believe in the electrical life, and so again we welcome you with the spirit of fellowship as apostles of this faith."

Mr. Plumb then turned the meeting over to President Berresford who delivered his presidential address on *Personal Observations in the Industry*. The address is printed in full in the July JOURNAL. Following his address, President Berresford welcomed the members of the Italian Commission to the Convention and called upon its chairman, Mr. Guido Semenza, for some brief remarks. Mr. Semenza thanked the president for calling attention to the presence of the Commission, and said in part: "Professor Ponti, another member of the Commission, has been with us until a few days ago. He was obliged to go back to Italy, and as he is also a member of your Institute he asked me to express his regrets at not being able to be present at this meeting. As to myself, I am an old member of this Institute but it is the first time I have had an opportunity to assist. Italy, after all the havoc of the war and the after effects of the war, is picking up, and we are doing some active and efficient work. One of the examples of the new life of the country is the sending over of this Commission to get into contact with your people and your works and to learn of all that is new in your great country. As I have had the honor of being the president of the Italian Electrotechnical Association, I am glad to bring you here the expression of the feeling of brotherhood, and they are sincere and we feel admiration for the splendid work you are doing."

The next order of business was the presentation of the annual reports of the Technical Committees. C. Edward Magnusson, chairman of the Educational Committee, H. P. Liversidge, chairman of the Power Stations Committee, E. B. Meyer, chairman of the Transmission and Distribution Committee and H. L. Hibbard, of the Marine Committee, presented the reports of their respective committees in abstract. The other committee reports were presented by title only.

President Berresford then invited Prof. Slichter, chairman of the Meetings and Papers Committee, to conduct the meeting and the first two papers of the program were presented. The paper on *Hydroelectric Developments at Niagara Falls*, by J. L. Harper and J. A. Johnson, was abstracted by Mr. Johnson, and the one entitled *Advances in the Art of Waterwheel Designs and Settings*, by W. M. White, was presented by the author.

The two papers were then thrown open for discussion, in which the following members participated: E. R. Pragst, W. Baum, W. M. Moody, W. J. Foster, E. M. Breed, and J. A. Johnson, with closures by the authors. The meeting then adjourned.

Sections Committee Luncheons. At 12:30 o'clock a luncheon was held under the auspices of the Sections Committee and was attended by the official delegates of the Sections, past chairmen of Sections, officers of the Institute and officers elect. The luncheon opened the first conference of Section Delegates for which a long program of topics for discussion ahd been prepared. A summary of this meeting is printed elsewhere in this issue.

Ladies Luncheon. A luncheon was tendered the ladies attending the Convention, at the University Club. There were 45 ladies present. The party was escorted from the Hotel Utah to the club house at 12:30 by the ladies Committee. The luncheon was followed by brief remarks from several of the ladies.

Organ Recital. An organ recital largely attended, was given in the Mormon Tabernacle at 3:00 p. m. This organ is a remarkable instrument, originally constructed by Utah artisans, mostly from native materials. Various additions and improvements have been made from time to time, until it now contains between 7000 and 8000 pipes divided into seven sections. Its mechanism is entirely electrically operated. A number of musical selections was rendered showing the wonderful possibilities of this mammoth instrument, after which President Grant, of the Mormon church, gave an interesting account of the experiences and work of the Mormon pioneers. The party was then escorted to the numerous points of interest in the Temple Block which contains the Tabernacle, the Temple and other historical buildings and monuments of the Mormon Church.

Wausatch Drive. At 7:30 p. m. the party was taken for an automobile drive over a scenic route through one of the many canyons radiating out from the city, and on the return passed along Capitol hill, where the State Capitol stands in prominent view. This two-hour ride in the cool of the evening, over excellent roads, through the wild mountain scenery of the Rockies, was greatly enjoyed by all.

Reception and Dance. The closing event of a busy day was the reception held in the Utah hotel ballroom at 9:30 p. m. This was an informal function, and after the presentations to the president and other officers of the Institute and ladies in the reception line were completed, dancing followed during the rest of the evening.

WEDNESDAY, JUNE 22

Technical Session. The session was opened by President Berresford who called the meeting to order, and asked Chairman Meyer, of the Transmission and Distribution Committee, under whose auspices the session was held, to take the chair and conduct the meeting.

The first paper of the morning was *Long-Distance Transmission of Electric Energy*, by L. E. Imlay, which in the author's absence was abstracted by the chairman. This was followed by a paper on *Voltage and Power Factor Control of 66,000-Volt Transmission Lines Connecting Two Generating Stations*, by Raymond Bailey, which was presented by H. P. Liversidge. A paper on *Voltage Regulation and Insulation for Large Power Long-Distance Transmission Systems*, by F. G. Baum, was abstracted by the author, after which a paper on *Some Transmission Line Tests*, by W. W. Lewis, was presented by the author. In the absence of the author Chairman Meyer presented a paper entitled *Notes on the Operation of Large Interconnected Systems*, by L. L. Elden, and the last paper of the morning, *Modern Production of Suspension Insulators*, by E. H. Fritz and G. I. Gilchrest, was presented by Mr. Gilchrest.

The discussion which followed was opened by W. I. Slichter and was participated in by L. P. Ferris, Buckner Speed, F. W. Peek, Jr., M. E. Skinner, C. L. Fortescue, Harris J. Ryan and F. G. Baum, and written discussion by J. T. Barron.

Bingham Excursion. At 12:30 on Wednesday the Convention party boarded a special train for the town of Bingham where the Utah Copper Company's mine is located. A substantial box luncheon was served on the train shortly after starting, and the trip to the mines occupied about two hours, passing through Garfield, which contains a large smelter, Arthur, where a very large copper concentrating plant is located, Magna, where the largest concentrating plant in the world is situated, and Bacchus, where there is a very large plant for the manufacture of high explosives and black powder. The train climbed the mountains by a devious route, along ledges, over bridges and through tunnels, many places affording remarkable views of mountain scenery.

Arriving at Bingham about 2:30, the train was taken up over the mine to the "E Level" where the party disembarked. Here was afforded a unique view of the open copper mine of the Utah Copper Co., the largest open copper mine in the world. It consists of a series of levels some 25 or 30 in number, extending to the extreme summit of the mountain. Each with its track on which the steam shovels and ore trains operate. In

times of maximum production the average daily output is 34 000 tons of ore and 32,000 tons of stripping, and 22 steam shovels, 56 locomotives and 1000 ore cars have been kept in operation day and night.

The town of Bingham, as viewed from the train, presents an unusual appearance. Situated at the bottom of a deep canyon, it is several miles long with only width enough for a single street.

On the return trip, stops were made at Arthur to inspect the concentrating plant, and Garfield, where the party visited the smelter works and Cottrell precipitation plant.

Music Recital. A piano, harp and vocal recital was given in the Hotel Utah ballroom at 8:30 p. m. at which several piano solos were rendered by Mr. Jacob A. Kahn, vocal solos by Mrs. Lloyd Weeter, and harp solos by Mrs. Marsh Boothby. The performance was much appreciated by a capacity audience which called for numerous encores.

Sections Committee Conference. The conference which commenced at the Delegates Luncheon was continued at the open conference held at 9:30 p. m. The program of Section and Institute affairs proposed for discussion was a long one and occupied the attention of the meeting until after 1:00 a. m. Further details of this meeting will be found elsewhere in this issue of the JOURNAL.

THURSDAY JUNE 23

Technical Session. After being called to order by President Berresford, the conduct of the meeting was turned over to Mr. F. G. Baum who announced that the papers for the morning would be read, after which the papers for both Wednesday and Thursday would be discussed together. The papers for the session were then presented as follows: *Voltage and Current Harmonics Caused by Corona*, by F. W. Peek, Jr., read by the author; *A Solution of the Porcelain Insulator Problem*, by E. E. F. Creighton and F. L. Hunt, read by Mr. Creighton; *Transformer for Interconnecting High-Voltage Systems or for Feeding Synchronous Condensers from a Tertiary Winding* by J. F. Peters and M. E. Skinner, abstracted by Mr. Skinner, and *Electric Strength of Air Under Continuous Potentials and as Influenced by Temperature*, by J. B. Whitehead and F. W. Lee, abstracted by Dr. Whitehead.

The discussion of the two days' papers which followed resolved itself into a rather general discussion of long-distance power transmission, with the following members participating: A. O. Austin, K. A. Hawley, G. I. Gilchrest, E. E. F. Creighton, H. J. Ryan, W. W. Lewis, F. W. Peek, Jr., A. W. Copley, L. H. Burnham, R. D. Evans, M. E. Skinner, J. P. Jollyman, J. A. Johnson, S. Barfoed, C. L. Fortescue, A. H. Lawton, L. P. Ferris, J. B. Whitehead, H. R. Summerhayes.

Ladies' Ogden Excursion. A party of 65 ladies left the convention headquarters at 10:00 o'clock Thursday morning on a special auto excursion to Ogden canyon. The ride covered a distance of 100 miles along the foothills of the Wasatch mountains. Luncheon was served at the Hermitage. The ride occupied nearly the entire day, the party returning at 6:00 p. m.

Board of Directors Meeting. At 12:30 the members of the Board of Directors present at the Convention assembled at luncheon after which a meeting was held. A notice of this meeting appears elsewhere in this issue of the JOURNAL.

Terminal Substation Inspection. A large party of the visiting engineers was taken by automobiles at 3:00 p. m. to the Terminal Substation of the Utah Power and Light Co., which is located about five miles outside the city. This company operates a hydroelectric development which includes 30 water powers and one steam reserve, and covers an area 375 miles long by 75 miles wide. The Terminal Substation is the terminus of three 130-kv. transmission lines aggregating 402 miles in length, the current from which is stepped down to 44,000 and 6600 volts in outdoor apparatus. The substation contains two 7500 kv-a., 6600-volt synchronous condensers.

The party divided into small groups each in charge of a guide who explained the construction and operation of the plant in detail, and afforded every opportunity for inspection and study of the system.

Lecture. Thursday evening was devoted to a lecture on the "Natural Parks of Utah" by Dr. Broaddus, in the Hotel Utah ballroom. The lecture was illustrated with beautifully colored lantern slides.

FRIDAY, JUNE 24

Technical Session. The last technical session of the Convention was called to order by President Berresford who called for the paper *Little Things from Little Places* by Guido Semenza. Mr. Semenza's paper gave a very interesting account of the electrical developments in Italy and the expansion of the electrical industry which has occurred since the war, due to changed conditions. He described some interesting contrasts in Italian and American practise many of which he ascribed to the larger number of individual manufacturers in Europe and the correspondingly larger number of variations in the design of electrical apparatus.

President Berresford then turned the meeting over to Mr. F. W. Peek, Jr., who called upon the authors to summarize their papers. The papers on *Synchronous Motors for Ship Propulsion*, by E. S. Henningsen, and *Magnetic Properties of Compressed Powdered Iron*, by Buckner Speed and G. W. Elmen, were presented respectively by Mr. Henningsen and Mr. Speed. In the absence of the author, the paper on *Heat Losses in Conductors in A-C. Machines* by W. V. Lyon, was presented by title only.

The joint discussion which followed was by the following contributors: H. W. Taylor, W. J. Foster, F. G. Baum, W. Fondiller, H. L. Hibbard, Guido Semenza, C. A. Copley, W. E. Thau, P. P. Ashworth, S. P. Grace, A. M. MacCutcheon, E. S. Henningsen and Buckner Speed.

President Berresford then declared the meeting adjourned.

Ladies' Auto Ride. An auto. ride to Parley's Canyon was enjoyed by 40 ladies, leaving the Hotel Utah at 11:00 a. m. A stop was made at the Country Club where luncheon was served.

Baseball Game. The baseball game which was scheduled between the Eastern and the Western members was called at 2:00 p. m. on the Municipal Baseball grounds of Salt Lake City. The teams were made up as follows:

East		West	
Kelley—Captain	cf	Davoud—Captain	cf
MacCutcheon	2b	Pratt	lf
Harms	3b	Evans	ss
Henningsen	lf	Stayner	3b
Dennison	1b	Ashworth	1b
Schifer	p	Merrill	rf
Johnson	ss	MacDonald	2b
Ward	c	Perrin	c
Watkins	rf	Gardner	p

Score: East 9
West 23
Umpire: Mr. Stevens
Scorekeeper: Mrs. Ashworth

Golf. On account of the large number of other conflicting diversions it seemed inadvisable to attempt to tie up the members for a number of consecutive afternoons at golf. Consequently the competition for these trophies instead of being held at match play, as has been customary in the past, was held at handicap medal play, the contest being decided in one round. Under the conditions this was considered preferable since interesting trips were scheduled for each afternoon and it was found that comparatively few members cared to give up these trips in preference to golf.

The John B. Fisken trophy, which is competed for in the Pacific Coast Sections was won by Charles P. Osborne of Port-

land, Oregon. The Mershon trophy was won by Howard Maxwell, Schenectady, N. Y.

Saltair Trip. The excursion to Saltair, the popular bathing and amusement resort of Salt Lake City, was the last event of the Convention and was largely attended. Many of the party enjoyed the novelty of bathing in the water of Salt Lake which is so dense that it is hardly possible to sink in it. At 7:00 o'clock dinner was served in the Ship Cafe after which Chairman Plumb called upon several speakers for some brief remarks. In closing, President Berresford said that he had attended every A. I. E. E. convention, except one, for 15 years so he could be considered an expert on conventions. The major part of a successful convention is an intelligently and well selected program—*well carried out.* The Salt Lake City Convention was different from all others held, in that it has fulfilled these conditions to the letter, exceeding expectations in every detail. He expressed his hearty thanks for the splendid achievement of the Utah Section.

Many of the convention party enjoyed various after-convention trips to the Pacific Coast, Zion Canyon, Grand Canyon, Yellowstone Park, etc.

SECTION DELEGATES' CONFERENCES

The Constitution of the Institute provides that each Section may be represented at the Annual Convention by "an official delegate" (usually the Chairman of the Section). The by-laws provide that the duties of these delegates shall be "to attend such meetings of the Sections Committee as may be held during the Convention, to exchange views and experiences in connection with Section activities and management, and to make recommendations of an advisory nature upon such matters to the Board of Directors." Delegates' deliberations at the Annual Convention therefore take the form of Sections Committee meetings.

A program committee for meetings of the Sections Committee was appointed, by Chairman John B. Fisken, some months prior to the Convention, consisting of Messrs. E. H. Martindale, Chairman, John C. Parker and Robert Sibley. This committee communicated with all Sections of the Institute inviting suggestions of topics for discussion, in response to which twenty-one topics were listed on the program for discussion at two meetings which were held, at luncheon on Tuesday, June 21 and during the evening of Wednesday June 22.

Delegates Present

The following is a complete list of the official delegates present, forty Sections being represented,—the largest representation at any meeting of delegates since the present pract se was established.

Section	Delegate
Akron	A. P. Regal
Atlanta	A. M. Schoen
Baltimore	John B. Whitehead
Boston	W. I. Middleton
Chicago	M. M. Fowler
Cleveland	A. M. MacCutcheon
Connecticut	L. W. W. Morrow
Denver	D. C. McClure
Detroit-Ann Arbor	C. Kittredge
Erie	M. C. Goodspeed
Fort Wayne	J. J. Kline
Indianapolis-Lafayette	J. Lloyd Wayne, 3rd.
Ithaca	J. G. Pertsch, Jr.
Kansas City	Geo. C. Shaad
Lehigh Valley	J. L. Beaver
Los Angeles	R. W. Sorensen
Lynn	A. K. Warren
Madison	Edward Bennett
Milwaukee	H. W. Cheney
Minnesota	J. D. Marshall
New York	W. I. Slichter
Omaha	P. H. Patton
Philadelphia	H. P. Liversidge
Pittsburgh	B. C. Dennison
Pittsfield	F. W. Peek, Jr.
Portland	W. C. Heston
Providence	F. N. Tompkins
Rochester	H. J. Schiefer, Jr.
St. Louis	J. L. Woodress
San Francisco	J. P. Jollyman
Schenectady	H. R. Summerhayes
Seattle	J. P. Growdon
Spokane	H. V. Carpenter
Syracuse	Rich D. Whitney
Toronto	F. R. Ewart
Urbana	E. A. Reid
Utah	J. F. Merrill
Vancouver	C. N. Beebe
Washington	L. D. Bliss
Worcester	Francis J. Adams

The officers and officers-elect present were: President A. W. Berresford, Milwaukee; Vice-Presidents C. E. Magnusson, Seattle, and E. H. Martindale, Cleveland; Manager, W. I. Slichter, New York; Secretary, F. L. Hutchinson, New York; Vice-Presidents elect, John C. Parker, Ann Arbor and F. R. Ewart of Toronto. Others who attended the luncheon-meeting on Tuesday included John B. Fisken, Chairman of the Sections Committee, and the following officers and past officers of Sections: A. H. Babcock, R. B. Bonney, J. C. Clark, C. R. Higson J. L. Hamilton, W. P. L'Hommedieu, A. S. Peters, H. T. Plumb and B. C. J. Wheatlake.

Chairman Fisken of the Sections Committee called the first meeting to order and made a brief statement outlining the purpose of the conferences, which was to afford an opportunity for the representatives of the Sections to confer together and with the officers regarding Institute activities, particularly those relating to Sections.

President Berresford made a brief address emphasizing the value and importance of the annual conferences of the delegates.

The program was then taken up, the first topic being, "Ways and Means of Stimulating Attendance and Interest in Section Meetings." A long discussion followed, lasting until the close of the session at 2:45 p. m., during which many valuable suggestions were made.

On Wednesday evening, June 23d a second meeting was held at 8:30 o'clock, during which the remainder of the program was discussed by the members referred to above and many others, the meeting being open to all interested.

A resolution was adopted recommending to the Board of Directors that a joint committee of representatives of the Institute and other national engineering societies having llocal sections be organized to study the conditions in various locatities and recommend some uniform method of cooperation of sec ions of these societies and other local technical organizations ofhigh standing within any one locality.

After a long discussion regarding the policy to be followed regarding the Institute's publications it was the consensus of opinion that both the monthly JOURNAL and the annual TRANSACTIONS should be continued. but that the duplication of expense by printing the same papers in both publications should be eliminated as far as possible by including in the TRANSACTIONS only material of permanent value and that matter of ephemeral value should be published only in the JOURNAL; also that highly theoretical and mathematical papers be printed by abstract only in the JOURNAL, but in full in the TRANSACTIONS, provision being made that any member may obtain a complete pamphlet copy without charge upon application to Institute headquarters, and that notice to this effect be published in the JOURNAL with the abstract.

Motions were adopted recommending the plan outlined above to the Board of Directors; also a motion to the effect that the TRANSACTIONS be furnished hereafter to Fellows and Members without charge over the annual dues but only upon application each year and upon payment of postage or other forwarding charge; that TRANSACTIONS be furnished to Associates only upon payment of a charge, not exceeding five dollars per year.

Many other recommendations were made to the Board of Directors and later in the Summer an abstract of the entire discussion at both meetings of the delegates will be printed in pamphlet form and forwarded to all delegates and officers of Sections, also, upon application to Institute headquarters, to any other member who is interested. Both conferences were exceedingly interesting and profitable to all in attendance, as indicated by the fact that the second session did not adjourn until 1:20 a. m. Thursday, June 23.

DIRECTORS MEETING

The Board of Directors met at a luncheon meeting on Thursday, June 23, 1921. Present: President A. W. Berresford; Vice-Presidents C. E. Magnusson and E. H. Martindale; Manager W. I. Slichter; Secretary F. L. Hutchinson; Vice-Presidents-Elect John C. Parker and F. R. Ewart. In the absence of a quorum various matters were acted upon tentatively, all to be submitted to the Executive Committee for ratification later.

AMERICAN ENGINEERS HONORED ABROAD

John Fritz Medal Presentation Ceremonies

The American delegation of engineers which recently visited London and Paris to present the John Fritz Medal to Sir Robert Hadfield and M. Eugene Schneider, as announced in previous issues of the JOURNAL, was received abroad with the highest honors, and the courtesies extended by large numbers of distinguished members of the profession in England and France marked the visit as one of international importance.

The delegation, representing the four societies of Civil, Mining, Mechanical and Electrical Engineers, consisted of: Mr. Ambrose Swasey, Chairmen; Mr. Charles T. Main; Mr. R. A. Cummings; Mr. J. R. Freeman; Dr. Ira N. Hollis; Mr. Jesse M. Smith; Colonel A. S. Dwight; Mr. C. F. Rand; Mr. William Kelly; Dr. F. B. Jewett; Dr. A. E. Kennelly; and Major-General George O. Squier.

The reception to the American delegation in London at the Institution of Civil Engineers was attended by an unprecedented representation of British Engineers. Almost all of those occupying official positions in any of the Great British societies were present, as well as many other distinguished members; and there were also present: Lord Brice; Sir Robert Horn; and the American Ambassador, Mr. George Harvey.

A warm welcome to the visitors was offered by Mr. John A. Brodie, President of the Institution of Civil Engineers, which was responded to by Dr. Hollis, who, in conclusion, presented Mr. Brodie an illuminated address of greeting from the Engineers of the United States to the Engineers of Great Britain, signed by the Presidents of the four American Societies. The presentation was acknowledged by Dr. Unwin, after which Lord Brice joined in the welcome to the American Engineers.

The award of the John Fritz Medal to Sir Robert Hadfield was made by Mr. Ambrose Swasey who mentioned that Lord Kelvin and Sir William White had been previous British recipients, and expressed gratification at the selection of another British scientist for this distinction.

Sir Robert Hadfield had prepared an address of thanks, printed in book form, and made only a brief verbal response on receipt of the medal. He stated that he accepted it as not only for himself personally, but as an expression of the engineers in the United States of the high regard of the work of the British engineers in the war.

During this visit Dr. Swasey was presented with an honorary membership in the Institution of Mechanical Engineers, and Mr. Rand was made an honorary member of the Iron and Steel Institute. Mr. Swasey and Mr. Rand were also made honorary members of the Athenaeum Club of London. The delegation was further entertained at several brilliant receptions and dinners given in its honor.

A wonderful reception was also accorded the delegation in Paris, where it went to present the medal to M. Eugene Schneider. The presentation took place at the headquarters of the Society of Civil Engineers, under the presidency of M. le Trocquer, Minister of Public Works. The presentation ceremonies were opened by M. Chagnaud, with a speech recalling the debt which France owed to her sister Republic. Dr. Hollis followed with a speech in which he expressed his admiration of France's effort, both in war and in peace. The medal was then presented by Mr. Swasey to M. Schneider, who said that he accepted the medal as an honor conferred on French engineers as a whole through him. At the conclusion of the ceremonies, M. Chagnaud announced that Mr. Swasey had been made an officer of the Legion of Honor, and pinned an insignia of the order on Mr. Swasey's breast.

A morning reception was tendered the delegation by M. Gustave Eiffel on the top story of the Eiffel Tower. At noon a luncheon was served on the second floor of the Tower, the guests including the members of the delegation, and a large number of leading French engineers and scientists. An address of welcome was made by M. Chagnaud and was responded to by Dr. Kennelly and M. Schneider.

The keynote of most of the speeches in both England and France was the international character of engineering, and the importance of developing intimate relations between the members of the professions of the different countries, leading to a better understanding between the nations.

ROYAL SOCIETY OF ARTS AWARD

Albert Medal to Dr. J. A. Fleming of London

Dr. John Ambrose Fleming, F. R. S., has been awarded the Albert Gold Medal of the Royal Society of Arts (Great Britain) for 1921, in recognition of his many valuable contributions to electrical science and its applications, and especially of his original invention of the thermionic valve, now so largely employed in wireless telegraphy and for other purposes.

Dr. Fleming, who has held the Chair of Electrical Engineering in University College of the University of London for 36 years, has been closely associated for the last 42 years with the practical and scientific developments of electricity in Great Britain. In 1879 he was scientific adviser of the Edison Telephone Company, formed to begin telephone exchange working in London, and for some years thereafter held similar scientific positions in connection with other companies. He assisted also the early progress of electric lighting in London, both in an advisory and a working capacity, one of his first accomplishments along this line being to carry out the electric lighting of one of the first ships to be so lit in the royal navy (an Indian troopship) when the illuminant was introduced in 1882.

After the initiation of practical wireless telegraphy by Senator Marconi in 1899, Dr. Fleming aided in its development, and directed some of the early constructional work in connection with the first long-distance wireless station at Poldhu. In 1904 he invented the first form of the thermionic valve or detector, which in its later improved forms due to subsequent inventors has been of great importance in wireless telegraphy and telephony.

The author of numerous valuable papers contributed to scientific societies, Dr. Fleming has also written various textbooks or treatises on electrical subjects which have had worldwide circulation. His most recent book is entitled "Fifty Years of Electricity, the Memories of an Electrical Engineer," in which he has described the chief notable achievements of Electrotechnics in the last half century, with many of which he has been intimately connected. He is a well-known lecturer in London, addressing working class audiences as well as uni-

versity and college, and frequently lecturing before scientific societies.

Besides the Albert Medal award of 1921, Dr. Fleming has received other recognition of his achievements. In 1892 he was given the Fellowship of the Royal Society; in 1910 he was awarded the Hughes Gold Medal by the Royal Society; twice did the Institution of Electrical Engineers award to him the Institution Premium, in 1903 and 1912; the Society of Engineers has awarded to him The Bermays Prize; and from the Royal Society of Arts he has received a Silver Medal.

The Albert Gold Medal was instituted in 1862 as a memorial of the Prince Consort, and is awarded annually for "Distinguished merit in promoting arts, manufactures, and commerce." Among its previous recipients are numbered Mr. Edison, who received the medal in 1892, and Alexander Graham Bell, to whom the award was made in 1902. It is the highest distinction given by the Royal Society of Arts.

PAGEANT OF PROGRESS EXPOSITION

Chicago, July 30-August 14

The Pageant of Progress Exposition, to be held in Chicago on the $5,000,000 municipal pier, July 30 to August 14, will be one of the notable expositions of today. Inaugurated to encourage trade and industry, the exposition will represent practically every phase of American industrial and commercial activity. There will be over 3½ miles of exhibits, divided into sections, and representing groups of industries. Among the features of the electrical exhibit will be wireless concerts, played nightly at Pittsburgh and received at the end of the pier, being relayed so as to be heard at 200 places at one time. An amusing exhibition will be electrically operated animals, "ranging from dragons to an electrical Fido."

In addition to the exhibits there will be many features to attract visitors, such as naval maneuvers, pageantry, street parades, races between some of the fastest motor boats in the world, and various athletic sports.

William Hale Thompson, mayor of Chicago, is president of the exposition, and the city's leading organizations are giving their support to make it a big success.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

New York, September 12-17

The Seventh National Exposition of Chemical Industries will be held at the Eighth Coast Artillery Armory, New York City, during the week of September 12th. This year's exposition, like previous ones, will be a most valuable and interesting display, representing every branch of the chemical industry, and introducing to the public many new and important developments in chemistry. Growing in importance each year, the National Exposition of Chemical Industries has come to be of much scientific and educational value, as well as an interesting industrial display. This year there will be delegations at the exposition from England, France and Canada. The progress of chemical research in the United States since the war started has been remarkable, and the exposit on to take place in September promises to be the greatest in the history of this country's chemical industry.

MANAGEMENT ENGINEERING

Management Engineering is the title of a new monthly magazine which made its initial appearance in July. It is edited by L. P. Alford assisted by Edward W. Tree, and published by the Ronald Press Co. of New York. The object of the new magazine, as described in its prospectus, is to help operating executives to attack managerial problems with definite plans and to employ to best advantage the machinery and labor at their disposal. The first number of the magazine, containing several articles by well-known engineers and executives, gives promise of fulfilling its mission very effectively. A convenient feature of the new pub ication is the printing at the head of each article the classification and index number corresponding to the system used in the Engineering Societies Library. Mr. Alford, both as an editor and an engineering executive, needs no introduction to an engineering audience; and Mr. Tree brings to the magazine his experience as associate editor of *Mechanical Engineering*. The new journal starts out well, and we wish it every success.

FRANCIS BAYARD CROCKER

Francis Bayard Crocker, past-president of the Institute, and one of the leading electrical engineers of the world, died on July 9, 1921, at his home in New York City.

Dr. Crocker was born in New York, July 4, 1861. From his childhood days he was interested in electricity, then barely known as a science, and as a boy he built successful telegraph and telephone lines. He attended school in New York, and was graduated from the School of Mines, Columbia College, in 1882.

The year following his graduation he formed with Charles G. Curtis the firm of Curtis & Crocker, and for five years they were engaged in patent and expert work almost entirely electrical. During that time they invented and patented the C & C electric motor, and established the company of that name. When Mr. Curtis had to withdraw from business on account of illness, Mr. Crocker joined with Schuyler S. Wheeler in the firm of Crocker & Wheeler, Electrical Engineers. This was the forerunner of the Crocker-Wheeler Company, now one of the prominent electrical manufacturing concerns of the country. Dr. Crocker was a director of this company at the time of his death.

Interested in the electrical industry, Prof. Crocker at the same time gave his energy and intellect to the development of the science. He founded the School of Electrical Engineering at Columbia University, and remained head of it for twenty years. As a teacher he endeared himself to thousands of students.

During the war Dr. Crocker was an advisor for the members of the Naval Consulting Board, refusing to become a member, however, on account of poor health. His researches in aeronautics were of great importance, and many of his discoveries are now in practical application. With Peter Cooper Hewitt he developed in 1917 the first helicopter in this country which was able to fly. Successful inventors frequently sought his advice and information, for his scientific knowledge was exceptional, extending into many fields besides those of electricity and aeronautics.

As Chairman of the first Standardization Committee of the A. I. E. E., Dr. Crocker gave his painstaking work to the standardization of electrical equipment. To obtain a complete standardization of electrical equipment throughout the world was one of the objects of his life, and in connection with this work he was one of the two American delegates to the International Electrotechnical Commission meeting in London in 1906. Lord Kelvin on this occasion said of him, "He is one of the world's two greatest electrical engineers."

Besides being Chairman of the Standardization Committee Dr. Crocker was active in the Institute in other capacities. He served as vice-president, president and manager.

Dr. Crocker was a former president of the Electric Power Club, and of the New York Electrical Society, and was a past secretary of the International Electrotechnical Commission.

With Dr. Crocker's death, engineers feel the loss of an able thinker and a great scientist, whose contributions to the world's progress will remain a lasting monument to his memory.

PERSONAL MENTION

SAMUEL ROBINSON, Commander, U. S. Navy, is now in the Bureau of Engineering, Navy Department, Washington, D. C.

J. V. HUNTER, western editor of *American Machinist*, in Chicago, has left that work to become editor of *Motor Service*, Chicago.

R. J. ANDRUS has left the Central Power Company, Grand Island, Neb., to locate with the Middle West Utilities Company of Chicago.

C. S. MCDOWELL, Commander, U .S. Navy, received the honorary degree of Doctor of Science from the University of Wisconsin, on June 22, 1921.

H. H. BRADLEY, of the International General Electric Company, has left the Schenectady office to become special representative for the company in San Juan, Porto Rico.

H. E. EISENMENGER is located with the New York Edison Company, New York City, He was with the Techno Service Corporation, New York, for the past year.

GORDON W. FALLIS has left his position as electrician with the Puget Sound Power & Light Co., Dieringer, Wash., to enter the Lighting Depratment of the City of Seattle.

M. M. KOCH, formerly field engineer with Henry L. Doherty, New York City, has gone to Denver, Col., where he will be with the Denver Gas & Electric Light Company.

F. L. HUTCHINSON, Secretary of the A. I. E. E., was married at San Diego, Cal., on June 27th, to Mrs. Grace Lawrence Duryee of San Diego, formerly of Elizabeth, N. J.

R. M. CRITCHFIELD, formerly assistant chief engineer of the Dyneto Electric Corporation, Syracuse, N. Y., is now associated with the Remy Electric Company, Anderson, Ind.

LEROY C. WILLIAMS has left his work as sales engineer with the Westinghouse Electric & Mfg. Co., San Francisco, and is engineer with the Alberhill Coal and Clay Co., Los Angeles.

ARCH ROBISON, formerly construction superintendent with the J. G. White Engineering Corporation, Marcus Hook, Pa., is with the Southern Utilities Company, West Palm Beach, Fla.

VICTOR T. MAVITY is now electrical engineer with the Chaparra Sugar Co., Chaparra, Oriente, Cuba. He was previously with the Colonial Sugar Co., of Central Constancia, Cienfuegos, Cuba.

R. A. GLADWELL, who has been associated with the General Electric Company since 1919, has left for Rugby, England, where he will be located with the British Thomson-Houston Company.

W. E. SANBORN is now a member of Cain & Sanborn, Inc., East Orange, N. J. Mr. Sanborn is secretary and treasurer of the firm. He had been located with Thomas A. Edison, Inc. Orange, N. J.

W. S. MURRAY and HENRY FLOOD, JR., who were engaged on the Superpower Survey of the U. S. Geological Survey, have opened an engineering office in the Grand Central Terminal, New York City.

GLEN D. BAGLEY, until recently with the Electro Metallurgical Co., Niagara Falls, N. Y., has become associated with the Union Carbide and Carbon Research Laboratories, Inc., Long Island City, N. Y.

HAROLD L. BALLARD, who has been instructor in Electrical Engineering at the University of Michigan, is at present associated with the Michigan State Telephone Company, Detroit, as transmission inspector.

E. T. STREET, until recently mechanical superintendent of the Standard Paint Co., Joliet Ill., has accepted the same position with the Rubenoid Co., of Bound Brook, N. J., and Joliet, Ill. He is located at Bound Brook.

ARTHUR E. ULRICH has been appointed Far Eastern representative of Joseph T. Ryerson & Son of Chicago, and will be located in the Tokyo office. He was formerly New York representative of the export department of the company.

FERMON L. NEWTON is at present manager of the Meter & Service Department of the Empire District Electric Co. of Oklahoma, at Picher, Okla. Until recently he was employed with the Wichita Falls Electric Co., Wichita, Falls, Tex.

J. D. SPARKS has been appointed representative in Utah, Idaho and Montana, of Landers, Frary & Clark, New Britain, Conn. Mr. Sparks was formerly employed in the sales department of the Western Electric Co., Salt Lake City, Utah.

C. E. DAVIES has been appointed managing editor of *Mechanical Engineering*, the journal of the American Society of Mechanical Engineers, to succeed the late L. G. French. Mr. Davies has been associate editor on this publication for over a year.

GEO. A. IRONSIDE, formerly chief operator and maintenance engineer of the Akitiki Power and Paper Co., Iroquois Falls, Ont., Canada, has become assistant superintendent of the Hydroelectric Power Commission, Cameron Falls, Nipigon, Ont.

W. J. COCHRANE, who has been doing maintenance and electrical construction work with the Canadian General Electric Co., Ltd., Toronto, Ont., has entered the consulting field. He is now a partner in the firm of Fitzgerald & Cochrane, consulting machinery engineers, Hamilton, Ont.

JOHN N. WALLACE of Wellington, New Zealand, representative of the Western Electric Co, Ltd., in Australasia for years, has severed his connections with that company and is now seeking connections with manufacturers of road-making and contractors' as representative for Australasia.

G. H. WIRTH has entered the employ of the Federal Board for Vocational Rehabilitation, as instructor in engineering subjects. He is located at U. S. P. H. Hospital-49, Philadelphia, Pa. Mr. Wirth was previously superintendent of construction with the Bainbridge Electric Co., Philadelphia.

FRANK L. DALAS, who has been in Mexico for some months, is at present installing a hydroelectric plant of 1000 h. p. for a sugar plantation in Zapotiltic, Jal., Mexico. Mr. Dalas has had a varied experience in electrical construction work since 1912, when he was graduated from the Carnegie Institute of Technology. Three years of this were spent in Upper Burma, where he was with the Burma Mines, Ltd., engaged in the erection of power lines and substations.

WILLIAM KENDRICK HATT, professor of civil engineering and director of Materials Testing Laboratory, Purdue Uni-

versity, Lafayette Ind., has been engaged as director by the Advisory Board on Highway Research, of the National Research Council. Director Hatt began his duties on July 1. The Advisory Board was established by the Division of Engineering of National Research Council, with the cooperation of Engineering Foundation, as a result of a conference held in New York last November, attended by many representatives of national engineering societies and industries interested in highways, as well as government highway departments and universities. These organizations are ready to give their cooperation to the highway research work, which is now placed on a national basis. Director Hatt's office is located in the building of the National Research Council, 1701 Massachusetts Avenue, Washington, D. C.

OBITUARY

Bertram Dewitt Wilber, of Indianapolis, died on June 9, 1921. Mr. Wilber was born in Big Rapids, Mich., and was graduated from the University of Michigan in 1899. For a short time after that he was employed by the Western Electric Company, of Chicago, leaving this for the Illinois Division of the Central Union Telephone Company. In 1905 he went to Indianapolis with the same company, and in 1911, was appointed state engineer of the Indiana Division of the Company, holding this office until April, 1920. He then became engineer of the Bell Telephone Company, which position he held at the time of his death. Mr. Wilber was a golf enthusiast, being amateur Indiana State golf champion in 1917, and city champion of Indianapolis in 1917 and 1919. He joined the Institute in 1912.

Albert Taylor, manager of the North Atlantic District of the Electric Storage Battery Company, died suddenly on July 6, 1921, in New York. Mr. Taylor was born in Liverpool, England, February 6, 1864. He was graduated from Princeton University in 1884, and after serving an apprenticeship with the Edison General Electric Company, joined the United States Electric Company, which later became a part of the Westinghouse Company. Entering the employ of the Stanley Electric Manufacturing Company, Pittsfield, Mass., in 1890, Mr. Taylor remained there for eight years, after which he was associated with the Electric Storage Battery Company, first as a salesman in the New York Office, then assistant manager and soon manager. Upon the division of the company's territory into five districts in 1920, he was selected as manager of the North Atlantic District. Mr. Taylor was well-known in the electrical industry, especially in central station and telephone fields, and his character won him many friends. He joined the Institute in 1901. He was also a member of the Engineers Club, Lawyers and Lotos Clubs of New York, and the Wykagyl Country Club of New Rochelle, N. Y.

Wilson Lee Campbell, general superintendent of the Automatic Electric Company, Chicago, and a Fellow of the Institute, died at Newton, Iowa, May 28, 1921. Mr. Campbell had been in poor health for about eighteen months previous to his death, but he continued his active duties so far as possible. Born in Muscatine County, Iowa in 1874, Mr. Campbell received his technical training at the Iowa State College, from which he was graduated in 1894. Entering the factory of the Strowger Automatic Telephone Exchange of Chicago in 1895, he started on his life work, the development and production of automatic telephone equipment. In that same year he became superintendent and engineer of the Merchants Mutual Telephone Company of Michigan City, Ind., and two years later was made superintendent of the Augusta Telephone & Electric Company of Augusta, Ga. In 1903 he entered the employ of the Automatic Electric Company of Chicago, as an expert on automatic telephone switchboards, and in 1908 became general superintendent of the company, holding this position until his death. Mr. Campbell contributed many valuable articles to engineering literature on the subject of the automatic telephone. He was a man of wide interests and keen sympathies, with a scientific point of view and impartial judgment which, with his enthusiasm, made him a dominant figure in the practical field of engineering.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (JUNE 1-30, 1921)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

Electrical Machinery

By T. A. Annett. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 431 pp., illus., 8 x 5 in., cloth. $3.00.

This course of study in industrial electricity is intended for home students and men engaged in the practical operation of electrical machinery. The author has made a special effort to present the subject in such a way that the student will avoid the difficulties which frequently occur in comprehending certain elementary laws, and to have all problems deal with things that occur in daily work.

Much of the text appeared in "Power," as part of a series of articles entitled "The Electrical Study Course."

Engineering Instruments and Meters.

By Edgar Griffiths. N. Y., D. Van Nostrand Co., 1921. 360 pp., illus., diagrs., 10 x 7 in., cloth. $7.50.

The writer has attempted to give a brief review of the appliances which have been devised for the measurement of some of the fundamental quantities of mechanical science, such as length, screw threads, area, volume, velocity, force, mass, work and temperature. The book should enable the reader to appreciate the advantages and drawbacks of the various types of instruments for making any particular measurement, and to choose the instrument best suited to his requirements. References to the literature accompany each chapter.

ENGINEERING OF POWER PLANTS.

By Robert H. Fernald and George A. Orrok. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 595 pp., illus., tables, 9 x 6 in., cloth. $5.00.

This is an epitome of the subject arranged for classroom use, in which an especial effort has been made to awaken a realization of the fact that engineering, although based on exact sciences, is not in itself an exact science, but requires the application of judgment; and to give the student some idea of the commercial side of engineering. The present edition includes corrections, slight modifications and reasonable additions.

FOUNDRYWORK.

By Ben Shaw and James Edgar. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitmans' technical primers.) 115 pp., illus., 6 x 4 in., boards, $1.00.

This little book is intended to supply engineers responsible for the designing machines that involve castings with some knowledge of the fundamental principles applied to their production in the foundry, in order that the difficulties involved in the casting of intricate forms may be understood by the designer and avoided in the design when possible.

GASOLINE AND OTHER MOTOR FUELS.

By Carleton Ellis and Joseph V. Meigs. N. Y., D. Van Nostrand Co., 1921. 709 pp., diagrs., 9 x 6 in., cloth. $10.00.

The authors of this work have endeavored to prepare a substantially complete survey of the field, which would include a description of practically every process of making gasoline and of most other motor fuels of prominence or promise.

The chief fuels considered are gasoline, benzine, alcohol and shale and asphalt oils. Much attention has been given to patent literature.

THE HIGH COST OF STRIKES.

By Marshall Olds. N. Y. and Lond., G. P. Putnams Sons, 1921. 286 pp., 8 x 6 in., cloth. $2.50.

In this book the author has attempted to analyze the costs to the public and to labor itself of the strike epidemic which followed the war and to show, as concretely as possible, the results, to labor and the whole country, of the theories of the professional labor leader as they become apparent in this large scale demonstration. He endeavors to make clear the wasteful absurdity of strikes as a means of controlling the division of the proceeds of production, and suggests other measurements for adjusting labor questions.

INDUSTRIAL ORGANIZATION AND MANAGEMENT.

By Hugo Diemer. Chicago, La Salle Extension University, 1921. 291 pp., illus., 8 x 6 in., cloth. $3.00.

Contents:—The Principles of Business Organization.—Types of Organization.—Locating an Industry.—Manufacturing Plants and Equipment.—Buying.—Receiving, Storing and Recording Materials.—Planning.—The Determination of Costs.—Methods of Collecting Material and Labor Costs.—The Distribution of the Expense Burden.—Standardization.—Scientific Management.—Time and Motion Studies.—Wage Systems, Welfare and Betterment Work.—Employment Problems.—Reports to Executives.

The contents illustrate the general purpose and scope of this book. The volume is intended for beginners and sets forth the elements of the subject clearly and concisely.

LICHTTECHNIK.

By W. Bertelsmann, and others. Edited by L. Bloch. Munchen and Berlin, R. Oldenbourg, 1921. 591 pp., illus., tables, 10 x 7 in., paper. 118M.

This volume embodies the substance of a series of lectures on illumination, delivered in September, 1920, at the Technical High School Charlottenburg, under the auspices of the Deutsche Beleuchtungstechnische Gesellschaft. The lectures were given by experts in various subjects. They discuss such questions as the theoretical bases of light production, photometry, hygiene of lighting, electric lamps, gas lighting, lighting with solid and liquid fuels and acetylene, reflectors and fixtures, organizations of lighting projects, lighting for streets, dwellings, halls, photography, etc. Current practise is followed throughout.

THE MANUFACTURE OF PULP AND PAPER: Volume 2.

By J. J. Clark and T. L. Crossley. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 182 pp., illus., 9 x 6 in., cloth. $5.00.

This is the second volume of the series of textbooks prepared under the direction of the educational committees of the pulp and paper association of the United States and Canada, as a course of study bringing together the fundamental facts of mathematics and elementary science and the principles and practise of paper and pulp making. The present book is devoted to mechanics, hydraulics, elementary electricity and chemistry. It is adapted for home study as well as for classroom instruction.

PHILOSOPHY AND THE NEW PHYSICS.

By Louis Rougier. Authorized translation by Morton Masius. Phila., P. Blakiston's Sons & Co., 1921. 159 pp., 7 x 5 in., cloth. $1.75.

The recent remarkable developments of physical theories, says the translator of this little book, cannot fail to have far reaching influences in philosophical thought. Physicists as a rule, are too much occupied with their special fields to give attention to matters of more general philosophical interest, and few philosophers possess the knowledge required for discussing and criticizing fruitfully the work of the physicist. Professor Rougier's very wide reading in physics has enabled him to present and interpret the new advances in physics in a way which should prove of interest to both philosopher and physicist.

RUBBER MANUFACTURE.

By H. E. Simmons. N. Y., D. Van Nostrand Co., 1921. 149 pp., illus., 11 x 8 in., cloth. $4.50.

This work is intended as a brief but complete survey of the rubber industry, from the methods in use for collecting rubber to the processes used for making rubber goods. The apparatus used in all parts of the industry is described.

DIE SYMBOLISCHE METHODE ZUR LOSUNG VON WECHSELSTROMAUFGABEN.

By Hugo Ring. Berlin, Julius Springer, 1921. 51 pp., 9 x 6 in., paper. 12M.

The symbolic method for the solution of alternating-current calculations has not had the adoption that, in this author's opinion, it deserves. He has therefore prepared this brief monograph to explain the method and to show its possibilities by practical illustrations of its application to the calculations usually needed by engineers engaged in heavy-current work.

TELEPHOTOGRAPHY.

By Cyril F. Lan-Davis. Second edition., by L. B. Booth. Lond., George Routledge & Sons, Ltd.; N. Y., E. P. Dutton Co., 1921. 116 pp., illus., plates, 7 x in., cloth. $2.00.

The book expounds the theory of telephotography, describes the commerical lenses and gives the practical methods in careful detail. The various applications are fully illustrated.

THE THIRD POWER KINK BOOK.

Compiled by the editorial staff of *Power*. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 264 pp., illus., 9 x 6 in., cloth. $1.50.

A collection of some three hundred unconventional but practical ways of meeting power plant emergencies, of the kind that arise in operation and in repair work.

THOMAS' REGISTER OF AMERICAN MANUFACTURERS.

Twelfth edition, 1921. N. Y., Thomas Publishing Co., 12 x 10 in., cloth. $15.00.

The twelfth edition of this popular directory of manufacturers and dealers presents no novelties in arrangement or contents. According to its publishers, however, over 200,000 changes have been made in order to keep the lists complete and accurate.

The Register is a directory of first hands in all lines, classified under several thousand subjects and fully indexed, so that the makers of any article may readily be found. Companies are also listed alphabetically, with data upon branch offices, capital, location, etc. A list of trade names is given, showing the owners of the various trade marks. In addition to these main divisions, the Register also contains lists of representative banks, commerical organizations, exporters and importers, and trade papers, making it a most complete work of reference for buyers and sellers.

WIRELESS TELEGRAPHY WITH SPECIAL REFERENCE TO THE QUENCHED-SPARK SYSTEM.

By Bernard Leggett. N. Y., E. P. Dutton & Co., 1921. (The Directly-Useful Technical Series.) 485 pp., plates, illus., 9 x 6 in., cloth. $12.00.

Although the quenched-spark system and the original Telefunken system have been extensively adopted in America, Australia, Asia and Germany, there is, the author states, no book in English which gives more than a mere outline of them, and much of the apparatus has never been illustrated and described in English. This volume is intended to fill the gap by providing a treatise on radiotelegraphy in which particular attention is given to the quenched-spark system. Bibliographies are appended to many chapters.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—June 22, 1921. Paper: "Interconnection Problems." Author: Mr. L. G. Tighe, Superintendent of Distribution, Northern Ohio Traction & Light Co. Attendance 30.

Cleveland.—May 17, 1921. Cleveland Engineering Society Club Rooms. Annual Dinner, followed by election of officers as follows: Chairman, I. H. Van Horn; Secretary-Treasurer, G. B. Schneeberger; Chairman Papers Committee, L. D. Bale. Subject: "Some Recent Developments in Scientific Research." Speaker: Mr. C. F. Ketering. Attendance 158.

Ithaca.—June 4, 1921, Montour Falls, N. Y. Subject: "Electrical Features of Cranes and Hoists." Speaker: Mr. James A. Shepard. Attendance 40.

Lynn.—June 15, 1921, G. E. Hall. Business meeting and election of officers as follows: Chairman, F. J. Rudd; Vice-Chairman, J. W. West; Secretary-Treasurer, D. F. Smalley; Assistant Secretary, W. M. Howe. Following the business meeting a social hour was enjoyed, the American Tel. & Tel. Co. exhibiting three interesting reels covering various phases of telephone work including wireless telephony. During the showing of the reels there was a wireless telephone instrument set up in the hall and demonstrated to the members. Attendance 250.

Milwaukee.—June 20, 1921, Blatz Hotel. Election of officers as follows: Chairman, Franklin J. Mayers; Secretary, Henry N. Wade.. Attendance 62.

Pittsburgh.—June 7, 1921, Fort Pitt Hotel. Election of officers as follows: Chairman, H. W. Smith; Secretary, E. C. Stone; Executive Committee, Messrs. J. C. Damon, L. R. Fox, B. C. Dennison, J. F. Peters, O. Needham, A. L. Broomall and E. G. Peterson. Following the business Mr. C. E. Skinner gave a talk on his trip to Europe in connection with the International Electrotechnical Commission. A social smoker followed at which new members were welcomed. Attendance 90.

Portland, Ore.—May 24, 1921, Blue Bird Inn. Election of officers as follows: Chairman, W. C. Heston; Secretary, D. W. Proebstel; Executive Committee, Messrs. R. R. Robley and J. E. Yates. The rest of the evening was given over to an informal dance. Attendance 113.

Rochester.—May 27, 1921, Eastman Building, University of Rochester. Election of officers as follows: Chairman, Sydney Alling; Secretary and Treasurer, A. M. Stetler; Executive Committee, Messrs. H. C. Ward, F. T. Byrne, G. A. Scoville and F. J. Stevens. Dr. J. R. Murlin and Dr. Harry Clough, of the University of Rochester, were the speakers of the evening. Dr. Murlin described many of the uses of electricity in physiology and medicine. He demonstrated the method of muscular stimulation by means of low voltage electric current, and also described electrical methods for measuring body temperatures. Dr. Clough described the development of the cardiograph and concluded his talk by a laboratory demonstration, Mr. C. T. Wallis being the subject. Attendance 40.

San Francisco.—May 27, 1921, Engineers' Club. Subject: "220,000-Volt Transmission." Speaker: Professor Harris J. Ryan, of Stanford University. Attendance 99.

Spokane.—May 20, 1921, Davenport Hotel. Election of officers as follows: Chairman, B. M. Merrill; Vice-Chairman, L. J. Posposil; Secretary-Treasurer, H. L. Melvin; Executive Committee, Messrs. D. F. Henderson, J. W. Hungate and James McNair. Subject: "Skagit River Power." Speaker: Mr. C. F. Uhden, Chief Engineer, Skagit River Power, City of Seattle. Attendance 70.

Syracuse.—May 20, 1921, Assembly Hall, Onondaga Co. Court House. Reelection of present officers. Subject: "Radio Telephony." Speaker: Dr. W. H. Nichols, of the Western Electric Laboratories. Attendance 175.

Worcester.—June 16, 1921, Worcester Polytechnic Institute. Business meeting and election of officers as follows: Chairman, George M. Hardy; Vice-Chairman, Francis J. Adams; Secretary-Treasurer, Dean J. Locke; Executive Committee, Messrs. Carl D. Knight, H. O. Tilton, and L. E. Pierce. Attendance 25.

PAST BRANCH MEETINGS

School of Engineering of Milwaukee.—June 17, 1921. Election of officers as follows: Chairman, F. P. Kasparek; Vice-Chairman, A. J. Ackermann; Secretary, L. F. Berg; Treasurer, Peter Stathas. Attendance 44.

Montana State College.—June 8, 1921. Election of officers as follows: Chairman, W. W. Husemeyer; Secretary R. D. Sloan. Attendance 28.

State College of Washington.—June 10, 1921. Election of officers as follows: Chairman, Julian O. Swanson; Vice-Chairman, Harry L. Garner; Secretary, Roy E. Kratzer; Treasurer, Hugh Allan; Reporter, Harold Vance. Subject: "Pointers for Student Engineers." Speaker: Mr. Dana. Attendance 16.

University of Washington.—June 7, 1921. Banquet at the University Commons. Mr. Lawrence Berg acted as toastmaster. Talks were given by Messrs. E. Axman, Nels Mattson, and W. Watson, graduating seniors, Mr. F. W. Budden, ex-Chairman, and Dr. C. E. Magnusson, Dean of the College of Engineering. Music was furnished by a four piece orchestra. Professor Harry E. Smith gave a talk on Industrial Insurance and the Workmen's Compensation Act. Attendance 37.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the address as they now appear on the Institute's records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—R. Coelho, 201 West 95th St., New York, N. Y.
2.—F. G. Doane, Box 168, Groton, Conn.
3.—W. F. Gantvoort, Kedongsarie 84, Soerabaia, Java, Dutch East Indies.
4.—L. E. Given, 72 West Adams Street, Room 634, Chicago, Ill.
5.—Conrad Jackson, Hood River, Oregon.
6.—J. M. Keller, Box 121, Sparrows Point, Md.
7.—Harry P. Meyer, 327 East 61st Street, Los Angeles, Cal.
8.—Basil B. Pilcher, 691 East 230th Street, New York, N. Y.
9.—M. J. Pouillon, 95 Straps Street, Ghent, Belgium.
10.—Fumiya Sakuma, Box 26, Terminal, Cal.
11.—Albert G. Scholer, Dundee Lake, N. J.
12.—Frank N. Tucker, 551 East 40th Street, Chicago, Ill.
13.—J. F. Warris, U. S. S. S-3, Union Iron Works, San Francisco, Cal.
14.—Martin Tracy, Tunnel Camp, Brittania Mines, Howe Sound, B. C., Canada.
15.—Harry Wilson, J. G. White Engg. Corp., Marcus Hook, Pa.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

MEN AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y., the employment clearing house of the Societies constituting the Federated American Engineering Societies.

Notices for the JOURNAL are not acknowledged by personal letter, but they will usually appear in the next issue that goes to press.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to EMPLOYMENT SERVICE, as above.

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

POSITIONS OPEN

ASSISTANT PROFESSORS, two, in Electrical Engineering Department. Location Georgia. X-268.

EASTERN TECHNICAL SCHOOL has opening for instructor in electrical machinery laboratory. Young men, graduates of a four years electrical or mechanical engineering course with some practical or teaching experience preferred. Opportunity for advancement excellent. Reply stating age, education and training, experience and salary desired. Location Boston, Mass. X-622.

INSTRUCTOR in electrical engineering to handle, principally, laboratory courses. Must have had experience as an assistant, or instructor, in a good laboratory. Additional testing experience with a manufacturing company is desirable. Location North West. X-629.

ILLUMINATING ENGINEER experienced for field work. Must have been doing this kind of work. Location New Jersey. X-674.

SALES ENGINEER preferably Electrical Engineer who understands arc lights and carbon installation. Carbons will be sold to moving picture house. X-684.

SALES ENGINEERS who have sold Mazda Lamps, lighting fixtures and motors. Two men needed. Drawing account and commission. Location vicinity New York City. X-685.

ELECTRICAL DRAFTSMAN, not over 45 years of age with several years' experience on designing of switchboards, substations and wiring diagramming. Location Pittsburgh. X-694.

JUNIOR SALESMAN to start in on the basis of a small salary plus a small commission. Position open after July 6th. Applicants must be of good personal appearance and of course must be over 21 years of age. Location New York City. X-699.

INSTRUCTOR for Electrical Department of prominent college in Western Pennsylvania. class room and laboratory work, d-c. and a-c., also special courses in electrical applications. Must have considerable practical experience in such fields as equipment and installation, central station manufacturing, winding storage battery, telephony, etc. Teaching experience desirable but not essential. State fully first letter, education, experience, age, salary expected. X-702.

TECHNICAL GRADUATE, preferably under 35 years of age, thoroughly conversant with principles, design and construction of high-tension high-frequency oscillatory apparatus such as condensers, oscillator, transformers, etc., which practically means a man with more or less wireless telegraphy experience. This apparatus is not used in wireless work of any kind, but circuits are more similar to wireless than any other types of circuits. There is an unlimited field for development as the process is so connected with the treatment of oils as to lead almost certainly, with its development, to revolutionary changes in many present refinery practises. Give details of past experience, present connections, age, present and anticipated salaries, etc. Location Missouri. X-710.

ENGINEER to operate an electrical hydraulic plant. It is not necessary that he know Spanish, though it would be advantageous. Location Central America. X-713.

INSTRUCTOR for Electrical Engineering subjects. Good engineering training and experience. Location Kansas. X-715.

GRADUATE ELECTRICAL ENGINEERS, over 30 years of age. Experience in cable manufacture while desirable is not essential. Location N. J. X-741.

INSTRUCTOR in physics. Only engineers looking for permanent teaching position will be considered. Application by letter only. Location N. J. vicinity New York City. X-742.

HEATING and VENTILATING ENGINEER preferably one who has had actual experience in the design and construction of forced circulation hot water system for scattered buildings. System requires considerable revamping especially in insulation of the underground pipes and a very considerable extension to take care of eight or ten new buildings we are proposing to erect. Location North Carolina. X-744.

POWER HOUSE SUPERINTENDENT for hydroelectric station operating under 280-foot head. Installation consists of two 11,000 h-p. vertical units. Must have had practical experience in operation and maintenance of hydroelectric plants. Prefer also that applicant have some engineering education. Application by letter. Location New York State. X-751.

ASSISTANT IN MATHEMATICS; subjects: Freshman mathematics, college algebra, trigonometry, and analytical geometry. Should have three or four years college mathematics andprefer men who have had some experience as instructors. Would appeal to young men who desire to take up graduate work in mathematics, while, at the same time, teaching enough classes to pay expenses. Send recent photograph and full statement of courses in mathematics studied and credentials regarding experience in teaching and ability in mathematics. Application by letter. Location Middle West. X-753.

INSTRUCTOR wanted for employees' classes in large electric utility corporation. Knowledge of psychological tests and rating scales desirable. Write fully experience and salary required. X-763.

MEN AVAILABLE

ELECTRICAL CONSTRUCTION ENGINEER, technical training, desires position on construction or maintenance work, affording opportunity for advancement. Eight years experience contracting, construction and maintenance. Three years electrical instructor. Two years assistant to consulting engineer. Available July 15th. New York City preferred. Associate A. I. E. E. E-2863.

GRADUATE ELECTRICAL ENGINEER, 1920; age 21; single. Have had experience as lineman with transmission company. At present local manager for same company. Have had much experience with steam engine operation and electric power plant machinery. Would prefer position with a power company. Associate A. I. E. E. E-2864.

ELECTRICAL ENGINEER, B. S. degree; age 21; unmarried. Six months testing experience. Desires connection leading to future responsibility with a power or manufacturing concern. Middle West location preferred. Initial salary immaterial. Available on two weeks notice. E-2865.

TECHNICAL GRADUATE, June 1921. Age 25, desires position with power company. Will go anywhere. Served two years as Lieutenant, Signal Corps, U. S. A. Available at once. E-2866.

ELECTRICAL ENGINEER, technical school graduate; age 32; married, desires position as assistant or chief engineer with large manufacturing corporation or power company, ten years valuable experience in testing, construction, repair, maintenance and operating work. Able to handle men and produce results. Associate A. I. E. E. E-2867.

ELECTRICAL ENGINEER; age 29; single; five years experience in power station and substation design. Familiar with office routine and purchasing of equipment. Two years experience steam engineering in the U. S. Navy as Lieutenant. Desires engineering or operating position. Employed, but desires change. Location immaterial. Associate A. I. E. E. E-2868.

PROFESSOR electrical engineering, member A. I. E. E. At present connected with a well-known school of engineering. Desires responsible position in a strong engineering school. Capable of directing department. E-2869.

AGENCIES FOR GREAT BRITAIN AND CONTINENT sought by graduate electrical engineer with partner, 14 years practical experience in U. S., England and Continent, both in the commercial and designing line of the industry, residing in England since 1914. Having extensive connections among buyers. Capable of handling schemes of any magnitude. E-2870.

ELECTRICAL ENGINEER, technical graduate; age 32; married. Eight years experience in power plant substation, underground distribution, lighting and industrial engineering. Capable of securing good men, handling men and building an efficient organization. Available within two weeks after an agreement. Best of references furnished. E-2871.

BUSINESS MEN. Position wanted on staff of financial, underwriting, or analytical organization to investigate commercial, technical and scientific soundness of industrial public utility and other business enterprises. Executive of broad business experience. E-2872.

MECHANICAL AND ELECTRICAL ENGINEER, technical graduate, two years shop, and one year general engineering, seeks connection with exporting firm or any cooperation dealing with American machinery trade in the Orient. E-2873.

ELECTRICAL ENGINEER, Assoc. A. I. E. E. Capable of advancing, desires change. Railroad preferred, sixteen years electrical experience not including seven years apprenticeship served in England. At present employed as chief electrician for a Southern railroad. Plenty of pep and executive ability. Would consider foreign offer. Salary can be mutually arranged. Available within 30 days. E-2874.

ELECTRICAL CABLE WORKS ENGINEER. Member A. I. E. E. Assoc. Mem. I. E. E. Three years works manager and five years chief electrician of large European cable factory. Sixteen years extensive cable experience in all. Familiar with estimating, manufacture, testing and laying, seeks responsible position in either factory or commercial side. Minimum basis $5000. Age 34. E-2875.

TECHNICAL GRADUATE; age 28; desires position as electrical engineer or assistant with central station company or constructing firm. Has had 6½ years experience in testing, construction and engineering. Available immediately. East or Middle West preferred. E-2876.

STEEL MILL ELECTRICAL ENGINEER with nine years broad practical experience in steelmills, foundries, blast furnaces, and coke plants, and thorough knowledge of the construction, installation, maintenance and operation of machinery used in and around such plants. Married; age 31; Assoc. A. I. E. E. Best of references; immediately available. E-2877.

GRADUATE ELECTRICAL ENGINEER; age 24; unmarried. Three years experience in automotive and machine design and drafting. Six months concrete construction. References. Desires connection with concern engaged in construction of plant installation. Location no object. E-2878.

ELECTRICAL ENGINEER; age 32; graduate of Yale, desires position with industrial firm preference for electrical apparatus or applicances. Experience, G. E. Test and engineering, street railway operation, electrical design and construction, production inspection and purchasing. E-2879.

GRADUATE ELECTRICAL ENGINEER of 1918, desires connection with industrial, engineering or power company. Experience in power plant and substation work, also in the installation and maintenance of motors for electric hoisting machinery and steel mill work. One year with Signal Corps in France. Single; age 26; Assoc. A. I. E. E. E-2880.

DESIGNING ENGINEER, member A. I. E. E. with wide and varied experience in designing of induction motors, synchronous motors, alternators and fractional horse power direct-current motors, would like to connect with a progressive concern. E-2881.

ELECTRICAL AND MECHANICAL ENGINEER, technical graduate; age 28; married, now engaged in steam power plant work in Hawaiian Islands, would like to connect with some firm doing this work in the Phillipines or the Orient. Experienced in the design and construction of complete steam-electrical power plants up to 5000 kv-a., and electrical substations. Available October 1st. Two year contract with transportation from San Francisco. Minimum salary $4200. E-2882.

MECHANICAL ELECTRICAL ENGINEER, inventor designer, extensive shop experience and well developed mechanical judgment. Qualified as an expert to undertake research, invention, design and preparation for manufacture of electromechanical and automatic devices or as a consultant or instructor. Position of responsibility, salary consistent with service desired. Available on short notice. E-2883.

GRADUATE ELECTRICAL ENGINEER, Assoc. A. I. E. E. age 28, seven years experience in charge of electrical maintenance and installation in various factories in this vicinity, one year teaching in State Trade School, and one year consulting service. Salary desired $5000; location preferred, New England or New York, although others considered. E-2884.

MACHINIST by trade. Five years experience in design, test, construction and operation of electrical installations. Three years sales engineer large oil company. At present employed in large industrial plant as designer. Available on short notice. E-2885.

ELECTRICAL ENGINEER wants opportunity in Washington State preferably Spokane; Cornell 1911; construction and operating experience large railway and interurban systems; entire charge substations construction; hydroelectric and steam plant experience; purchasing agent for erection large factory, power plant and equipment; successful salesman; wants engineering or sales representation. E-2886.

ELECTRICAL MECHANICAL ENGINEER. Technical graduate; twelve years practical experience, six being in design, construction, operation of steam power and industrial plants; includes substations, overhead and underground transmission systems. This covers estimating, specifications, purchasing and supervision of design and drafting. Available immediately. Salary $3900. E-2887.

YOUNG MAN, age 24, desires position where following will prove of value. Two years electrical construction work such as installing small power switchboards, motors, generators, lighting circuits, etc. Would prefer position in armature winding or motor repair shops. Graduate of N. Y. E. S. Available immediately. Would also accept factory maintenance job. E-2888.

GRADUATE ELECTRICAL ENGINEER, age 36; single, with fifteen years experience on electrical tests and construction will be available about September 1st. Has just completed the installation of the electrical equipment for a steel tube mill with a connected motor load of approximately 5000 h. p. the motors ranging in capacity from 1200 h. p. to fractional h. p. Best of references from past and present employers E-2889.

ENGINEER, age 28; graduated abroad. One year University courses in U. S. and three years experience abroad in electrical engineering, desires position with operating or construction company, with opportunity for experience. Interested in electric traction and hydroelectric development. E-2890.

ELECTRICAL ENGINEER. Ten years experience in design, construction and operation of hydroelectric stations and electrical equipment for large industrial installations. Age 32; seeks position offering great enough opportunities to warrant permanent residence. Available on short notice Excellent references. E-2891.

ENGINEER DESIRES TEACHING POSITION. University North Dakota, Cornell University; age 41; married. Taught mechanical drawing, descriptive geometry, electrical engineering and laboratory. Eight years practical engineering experience. Location New York City or Middle West. E-2892.

PROFESSORSHIP OF ELECTRICAL ENGINEERING. Taught in large university for fifteen years electro-magnetic theory, d-c. and a-c. practise, transient phenomena, radio telegraphy, etc. In charge of important engineering operations during the war (Major). Now on engineering research. Desires suitable position in University with increasing research activities. E-2893.

RECENT GRADUATE ELECTRICAL ENGINEER; age 27. Four years practical experience in marine electrical work and one year with steam railroad. Position desired with some well established electrical concern wanting a man with practical and technical knowledge. Location U. S. Salary $1800 to start. E-2894.

CONSTRUCTION AND PLANT ENGINEER. Technical graduate, 1911. Fourteen years broad general experience in construction, operation and maintenance and management of power systems and industrial plant equipment. Good general business training and experienced in handling men. Can plan layout, purchase material, take entire charge of construction and produce first class work. Traveled widely, speaks Spanish, makes best use of material and men available, does trouble shooting and emergency repairs and keeps things running. Now employed, salary $3000. Age 34; wife and child. Taking Alexander Hamilton Institute course. Desires permanent position with first class concern in the West. No objection to isolated location, salary governed by location and opportunities. Available at short notice. E-2895.

EXECUTIVE AND INDUSTRIAL ENGINEER or sales engineer for Puget sound territory to manage branch factory or sales. Excellent training and experience. E-2896.

ELECTRICAL CHIEF, age 34; married. Fourteen years supervising experience on electrical installation work in building, also distribution systems, lighting, power and interior communication work abroad all types of government warships, transports, and submarines. Experienced in handling draftsmen, organizing and capable of producing production. Desire position with some established firm where position is permanent and advancement assured. E-2897.

SALES OR CONSTRUCTION ENGINEER. Graduate electrical engineer; age 35; is desirous of locating in the East, vicinity preferably Philadelphia or New York. Twelve years experience in street railway operation and two years sales engineering. Salary $4500. E-2898.

ELECTRICAL ENGINEER; age 34; single; technical graduate. Two years General Electric Company, testing department; two years Public Utility Co., five years research work on automotive equipment, desires position as experimental or research engineer. Assoc. A. I. E. E. and Member American Mathematical Society. E-2899.

GRADUATE ELECTRICAL ENGINEER, 1915 Univ. of Penna. age 28; single. Six years experience in design, construction and operation of high-tension generating and substations, of which four years was in the employ of large public utility and two years in industrial plants. Member A. I. E. E. Location Middle Atlantic States. Salary $3000. E-2900.

RESEARCH ENGINEER, graduate E. E., experienced in research and development of electrical appliances, thoroughly familiar with patents and patent law. About to be registered as patent attorney. Can handle small laboratory or assist in management of large concern. E-2901.

MECHANICAL AND POWER ENGINEER; age 29; single. Technical graduate, B. S. and M. E. Seven years experience along broad lines, chemical manufacturing, machine shop, metallurgy, sugar engineering, industrial and power plant practise and operation, layout, design, calculations, steam, water, air heating and distribution, research, etc. Has business and executive ability and can handle men; desires connection as mechanical engineer, power plant or in similar responsible position. E-2902.

ELECTRICAL ENGINEERING GRADUATE; 1920; single. One year General Electric

test, desires position in sales or public utility work. Available on short notice. Location preferred Southeast. E-2903.

SUPERINTENDENT, mechanical and electrical construction, operation or maintenance. Capable organizer and executive with wide industrial and power plant experience. E-2904.

UTILITY MANAGER desires new connection. Successful operator of several utility properties. Present connection manager in town of 15,000, electric light, power and gas. Considerable experience, power plant improvement and operation. Twelve years experience. Associate A. I. E. E. Available after August 1st. Best references including present employers E-2905.

ELECTRICAL AND MECHANICAL ENGINEER, technical graduate. Seven years experience, wants position with firm as operating or maintenance superintendent. Four years with large electrical manufacturer in manufacturing and testing and three years in engineering department of same company, in applying electrical machinery and in making plant surveys for improvements. E-2906.

TECHNICAL GRADUATE; age 30, desires position as assistant to electrical engineer or superintendent. Nine years experience including shop, testing, operating and maintenance work. E-2907.

ELECTRICAL ENGINEER; age 28; Member A. I. E. E., Jr. Mem. A. S. M. E., Chief electrician U. S. N. Nine years service. General foreman of construction and assistant engineer in charge of construction. Ten years practical experience, five years d-c. and five years a-c. Wishes position where chance of advancement. Location anywhere. E-2908.

ELECTRICAL INDUSTRIAL ENGINEER; age 36; with executive ability and broad experience desires to reenter industrial work after teaching electrical engineering subjects for three years. Suitable living conditions for young children essential. Salary based on responsibilities shouldered. Can go to New York for interview. E-2909.

PHYSICIST, Member American Physical Society; Associate A. I. E. E. now in charge of technical physical laboratory; desires position of responsibility in the research or development field of pure or applied physics. New York City or vicinity preferred. E-2910.

YOUNG MAN, university trained in electrical engineering with four years experience in manufacturing, testing and sales of electrical machinery. Work of a commercial nature preferred. E-2911.

EXECUTIVE. Electrical Engineer; four years practical experience power plant engineering, high potential and radio; technical graduate. Exceptionally valuable G. E. Co., test and complaints. One year construction engineer steam turbines and electrical equipment. Available after September 1st. Prefer executive position with opportunity for advancement. Age 27. Present salary $2600. E-2912.

ELECTRICAL ENGINEERING GRADUATE; age 26; married. Four years factory experience; one with hydraulic turbine manufacturer, desires position in West giving experience in preliminary investigation, design or construction of hydroelectric plant. E-2913.

BROWN AND CORNELL UNIVERSITIES (degree from each) age 26; single. Taught electrical engineering, electricity, drawing, heat, and telegraph engineering; desires to teach electrical subjects provided not at all laboratory. E-2914.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before August 31, 1921.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

Vol. XL | SEPTEMBER, 1921 | Number 9

The Magnetron

BY ALBERT W. HULL

Research Laboratory, General Electric Co., Schenectady, N. Y.

Introduction

IN PRESENTING to you this youngest member of the electron tube family, I am both aided and embarrassed by its family history. I am aided by the fact that you are already acquainted with electrons, so that I need waste no time in explanation or argument regarding their existence. You believe in these little cannon balls which jump out of the hot filament, fly across the vacuum, and plunge into the anode. You have seen them heat the tungsten anode of an X-ray tube to its melting-point in a fraction of a second. Most of you believe that when a current flows through a wire it is these same little electrons, and nothing else, that stream through the wire, like water flowing through a pipe.

But while electrons are among your engineering acquaintances, they are not accepted, so to speak. They are associated with wireless magic and micro-amperes, read through a telescope. And so, as engineers, you view them with aloofness, as interesting playthings, not engineering tools.

It is quite reasonable that you should view them so, but you are wrong. Electron devices are not small, they are only young. They are growing up. You have heard of their slow development from micro-amperes to milliamperes. Since you last heard from them they have grown from milliamperes to amperes; and before you know it, before you know *them*, if you don't watch out, they will have grown to kiloamperes.

I therefore present to you, tonight, the magnetron as an engineering device. I shall suggest some applications. You, with your greater experience, can, I hope, think of many more.

I shall first state briefly what the magnetron is; then why it is, that is, the theory of its operation and how it is related to the other "trons"; then what it will do; and, finally, what I hope it will do.

Definition

"Magnetron" is a Greeko-Schenectady name, as Mr. Lee DeForest calls it, for a vacuum electric device which is controlled by magnetic field. It belongs to the kenotron family. Kenotron, which means, as those of you who are Greek scholars will readily recognize, a "thing with nothing in it," is a general term which we apply to all our vacuum thermionic devices. Examples of simple kenotrons are the X-ray tube and

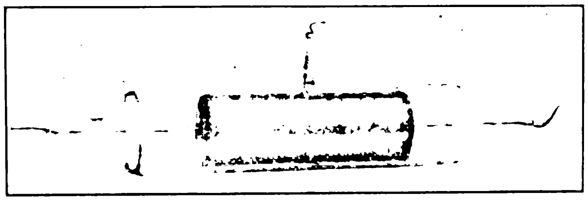

Fig. 1

kenotron rectifier. The name pliotron is intended to mean a thing that amplifies; the dynatron, a thing that generates power; and the magnetron, a thing operated by magnetic field.

Structurally, the magnetron is a simple kenotron whose elements are symmetrical about an axis. It may consist of a straight filament surrounded by a cylindrical anode, as in Fig. 1; or a straight rod-shaped anode, surrounded by a helical filament, as in Fig. 2; or it may consist of three elements, a filament, grid, and anode, all symmetrical with respect to a common axis, as in Fig. 3. Symmetry, circular symmetry with respect to an axis, is essential. The reason for this will appear later. The fundamental distinguishing

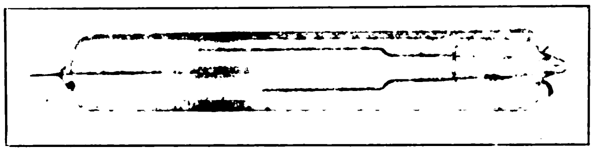

Fig. 2

structural feature of the magnetron is its symmetry.

A second structural characteristic, in addition to symmetry, is essential for a practical magnetron; namely, that it should be of such form that a magnetic field parallel to the axis can be conveniently and economically applied. This is accomplished in the tube shown in Fig. 1 by making the glass envelope a tight

Lecture delivered at the Annual Meeting of the A. I. E. E., New York, N. Y., May 20, 1921.

fitting cylinder, concentric with the electrodes, so that a solenoidal coil may be wound directly on the glass; and by slotting the anode longitudinally, so that the magnetic flux produced by the solenoid will not be neutralized by eddy currents. The slotting of the anode is especially important when high-frequency alternating magnetic fields are to be applied.

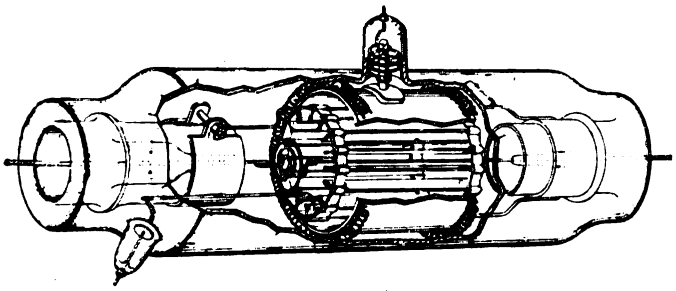

Fig. 3

Electrically, the magnetron is a valve, operated by magnetic field. Its characteristic may be stated as follows: If a constant voltage is impressed between cathode and anode, the current that flows through the tube is not affected by a magnetic field weaker than a certain critical value, but falls to zero if the field is increased beyond this value. The magnetic field must have its lines parallel to the axis of the tube.

This characteristic may be made clear by some examples.

Fig. 4 shows the tube and circuit. The cathode is a straight tungsten filament, the anode a circular cylinder. A battery, B_1, heats the filament to incandescence, and another battery, B_2, impresses a constant voltage between cathode and anode, the anode

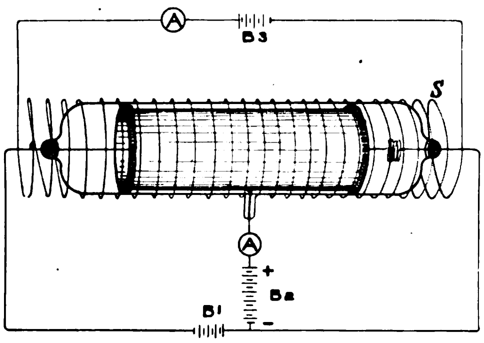

Fig. 4

being positive. This is a plain kenotron arrangement, and if the temperature of the filament is high enough, a current will flow across the vacuum, as you know. The magnitude of the current will be limited either by the temperature of the filament or the voltage of the anode, whichever gives the *smaller* value of current.

The addition of a magnetic field, produced by the solenoid S, imposes a third type of limitation upon the current flow. If the field is weaker than a certain critical value, the full current will flow, limited only by filament temperature or voltage; if the field is stronger than this critical value, no current will flow. The action of the magnetic field is thus similar to that of a valve in hydrodynamics, or a contact relay in electrical circuits. In fact, the same characteristics would be obtained if the tube in Fig. 4 were replaced by a resistance, and the solenoid S, instead of being

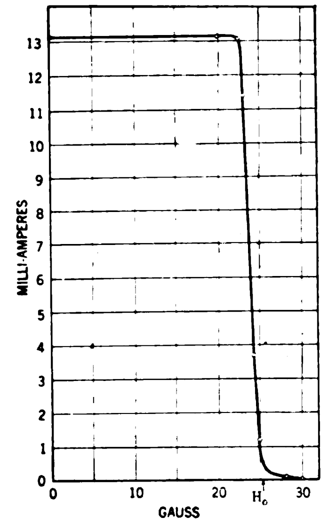

Fig. 5

around the tube, were used to energize a relay that opened and closed the circuit of the battery B_2. As long as the magnetic field is weaker than a certain critical value, the relay remains closed, and full current flows; when the field becomes stronger than this critical value, it opens the relay, and no current flows. The magnetron relay has the advantage of no moving parts and no inertia—its speed is limited

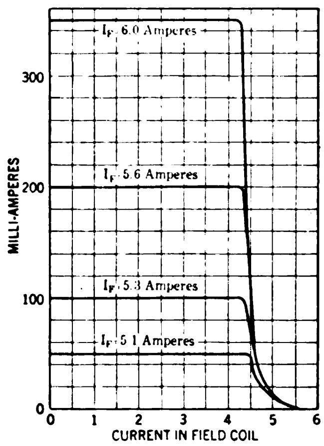

Fig. 6

only by the time necessary to build up the magnetic field, which may easily be made less than one millionth of a second. It has the disadvantage that it is a high-resistance relay, since it requires a vacuum tube in the circuit.

A typical gauss-ampere characteristic is shown in Fig. 5. The abscissas are gausses, or lines per square

centimeter, the ordinates current through the tube. The anode was a cylinder 1½ in. in diameter and 4½ in. long, the cathode a 4-mil straight filament. It is seen that for all values of the magnetic field less than 23 lines per square centimeter, the valve is wide open, and the same current flows through the tube as when the

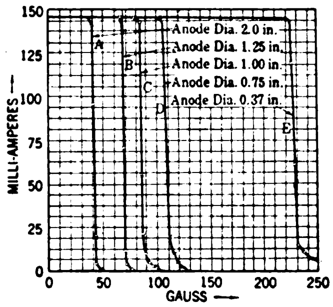

FIG. 7

magnetic field is zero. For fields larger than 25 lines per sq. cm. the valve is closed, and no current flows. It will be noted that the transition from "open" to "closed" condition is not quite abrupt. This is due mainly to lack of symmetry. In a well evacuated perfectly symmetrical tube, the transition should be very nearly abrupt.

In Fig. 5 the maximum current is limited by the voltage between cathode and anode. The effect of the magnetic field is the same, however, whether the maximum current is limited by voltage or temperature. This is shown in Fig. 6, which gives the characteristics of the same tube at four different filament temperatures. In the upper curve the temperature is high enough so that the current is limited only by the volt-

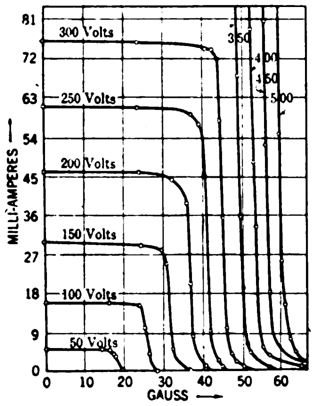

FIG. 8

age. In the other three, the current is limited by the filament temperature.

The critical value of magnetic field that is just sufficient to close the valve depends only upon the diameter of the anode and the voltage across the tube. It is inversely proportional to anode diameter, and directly proportional to the square root of the voltage between cathode and anode. Its dependence on anode diameter is illustrated by Fig. 7, which shows the characteristics of four different tubes, with diameters from ⅜-in. to 2 in., at the same voltage. The maximum currents are limited by filament temperature to the same value. It is seen that the 1-inch diameter anode requires twice as much field as the 2-inch one, and the

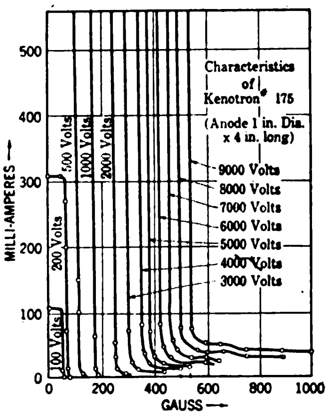

FIG. 9

⅜-in. one twice as much as the ¾-in. one; that is, the critical field is inversely proportional to the diameter.

The effect of varying the voltage is shown in Figs. 8 and 9, which give the characteristics of the same tube at different voltages. The anode in Fig. 8 was a cylinder 2 in. in diameter and 2 in. long; in Fig. 9 a cylinder 1 in. in diameter by 4 in. long. It will be noted that the field required to close the valve at 500 volts is only half as great as at 2000 volts, and one-quarter as great as at 8000 volts; that is the critical field is proportional to the square root of the voltage. Only the lower portions of the curves in Fig. 9 could be taken because of the excessive heating of the anode. The full current at 9000 volts is 100 amperes. This was reduced to a few milliamperes by the magnetic field alone.

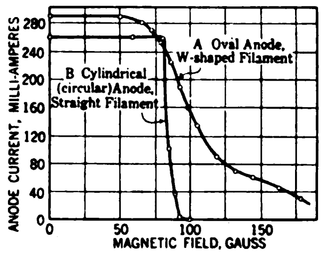

FIG. 10

The necessity for symmetry of construction is shown in Fig. 10. Curve *A* shows the characteristics of a magnetron, with straight filament and cylindrical anode 1 in. in diameter by 4 in. long, at 250 volts; curve *B*, that of a kenotron with *W* shaped filament and oval anode, ¾ in. thick by 1½ in. wide by 2 in. long.

The necessity for making the lines of the field parallel

to the axis of the tube is shown by Fig. 11. Curve *A* shows the characteristic of a 1-in. by 4-in. tube with field parallel to its axis; curve *B* the characteristic of the same tube at the same voltage with the lines of the field at an angle of 20 deg. to the axis of the tube.

A more sensitive form of magnetron may be made by putting the anode inside the cathode instead of outside, as in Fig. 2. The tube and circuit are shown in

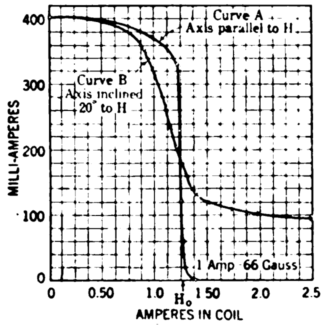

Fig. 11

Fig. 12. The cathode is a helical tungsten filament, ¼ in. in diameter, the anode a straight tungsten wire $^1/_{100}$ in. in diameter. The magnetic field required to operate a magnetron with internal anode is smaller than for an external anode of the same dimensions by a factor equal to the ratio of the diameters of the cathode and anode. In the tube shown in Fig. 12 this ratio is 25, so that the field required to close the valve is only $^1/_{25}$ as great as for a tube of similar dimensions with external anode; *i. e.*, a tube with 10-mil straight filament surrounded by a ¼-in. diameter anode. The cutoff is less abrupt, however, in the internal anode tube.

Fig. 13 shows the characteristic of this tube at 110 volts. A rotating commutator interrupted the heating current during the brief intervals while the

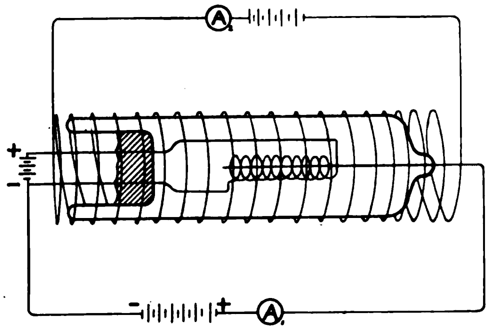

Fig. 12

measurements were being made. At first glance one would say that this characteristic is not steep enough to be of any interest, like that of the unsymmetrical tubes shown in Figs. 10 and 11. It will be noted, however, that the fields required are manifold smaller than in Figs. 10 and 11, so that a field only ten times that of the earth is sufficient to reduce the current to half value, and the effect of the earth's magnetic field is clearly seen, shifting the whole curve to the right by $^6/_{10}$ of a gauss.

The slope of the curve is due to the initial velocities with which the electrons are emitted from the filament. These initial velocities are known, and it is possible to calculate their effect. The crosses in Fig. 13 show the calculated results, the experimental values being represented by the circles. If the initial velocities

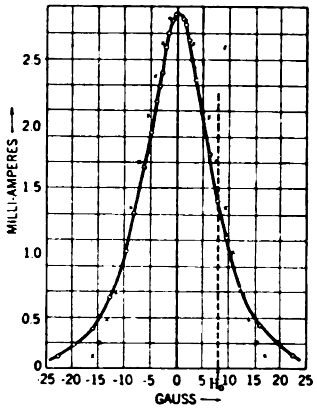

Fig. 13

were very small, the characteristic would be represented by the vertical line H_o. This condition can be approximated by using a very low temperature filament.

Theory of Magnetron

The foregoing discussion has aimed to define what the magnetron is—an inertialess, high-resistance valve, operated by magnetic field. I shall now attempt to explain why it is—the theory of its operation.

The mathematical theory of the magnetron will be found in the Aug., 1921 number of the *Physical Review*. It need be referred to here only to point out that the solutions are simple and apparently rigorous and agree with the experimental facts outlined above.

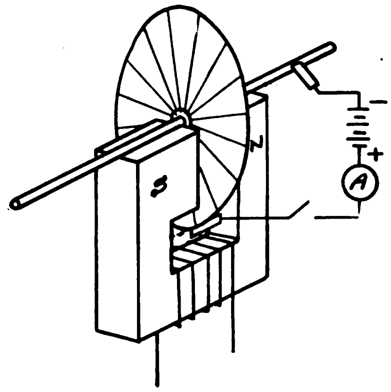

Fig. 14

The operation of the magnetron may best be understood from an analogy.

The magnetron is closely analogous to a direct-current motor running without load. In order to avoid commutators, I shall take the case of a unipolar

motor (Fig. 14), composed of a slotted disk capable of rotating between the poles of an electromagnet. Current is led into and out of the disk by brushes on the axis and periphery respectively. When the switch is closed a large current flows, as indicated by an ammeter A, and the flow of current across the lines of the magnetic field develops a torque which starts the disk in rotation. The rotation develops a back e. m. f., which, if there is no resistance to rotation, will increase until it exactly equals the e. m. f. of the battery, and the current through the ammeter A will fall to zero. In practise the current does not fall quite to zero, because of the friction.

I have described the operation of the motor in ordinary engineering language. I will now describe it again in greater detail, using the language of electrons, but introducing no new ideas. Instead of the simple statement that current flows when the switch is closed, I will be more specific, and say that electrons flow; for it is electrons, and nothing else, that carry electricity through wires, and they flow from negative to positive, in this case from the axis toward the periphery. The disk begins to rotate because a conductor

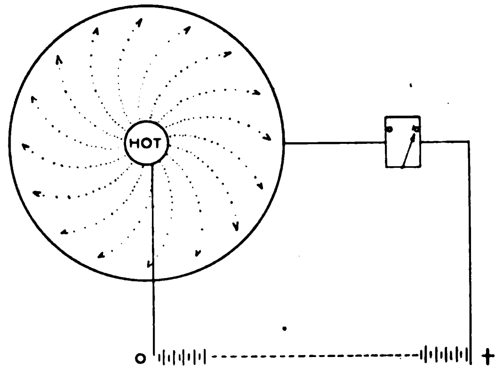

FIG. 15

carrying current in a magnetic field is acted on by a mechanical force. Does the force act on the conductor or the current that is flowing in it? This question may be answered definitely. The force acts on the electrons, tending to make them move in spiral paths instead of radially. Since the electrons cannot move tangentially without taking the disk with them, on account of the slots, the disk begins to rotate. The electrons would drag the disk with them even in the absence of slots because of electric resistance.

The rotating disk carries the electrons with it, giving them a tangential velocity. The electrons will therefore be acted upon by an additional component of force, at right angles to this tangential component of velocity, that is, radially inward, in opposition to the impressed e. m. f. When maximum speed is attained, if there is no friction, the radial flow of the electrons is completely stopped by the back e. m. f. Their motion becomes entirely tangential, and the force acting on them entirely inward, in opposition to the e. m. f. of the battery. We thus have a simple case of a conductor at whose terminals an e. m. f. is impressed by a battery, but no current flows. The explanation of the lack of current is a back e. m. f., produced by the motion of the electrons in the conductor across the lines of magnetic force.

Turning now to the magnetron, which is shown in cross-section in Fig. 15, it is obvious that the electrons that start to move radially outward, under the influence of the impressed e. m. f., will be acted on by

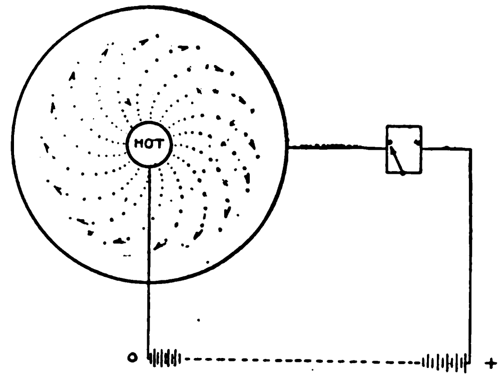

FIG. 16

a tangential force tending to curve their paths into spirals, and that the tangential component of velocity thus imparted will react with the magnetic field (which is normal to the plane of the figure) to produce a radial component of force on the electrons, inward toward the filament, in opposition to the e. m. f. of the battery. If the magnetic field is sufficiently strong as shown in Fig. 16, this inward force, *due to the circular motion* of the electrons, will just balance the e. m. f. impressed by the battery. Hence the electrons, though perfectly free to move about in the vacuum, are unable to reach the anode, even though driven by an e. m. f. of 10,000 volts or more. The back e. m. f. due to their circular motion equals the impressed e. m. f.

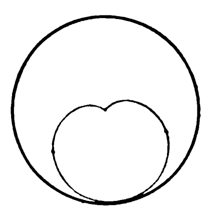

FIG. 17

The question will naturally arise, what becomes of the electrons that are thus left stranded in space? Do they return to the filament, or do they continue to circle around it forever? The answer is simple and definite. They do both. I have obtained a simple solution of their approximate paths, and Langmuir has succeeded, by approximation, in calculating the exact path. It is shown in Fig. 17 and is represented very nearly by the equation $r = R\ (\sin\ 2/3\ \theta)^{3/2}$ The electron flies out as near to the cylinder as it can

go, depending on the strength of the magnetic field, then back to the filament, then out again, etc., *ad infinitum*, or until it strikes a gas molecule or some unsymmetrical part of the tube. The space soon becomes filled with these planets (in less than one one hundred millionth of a second, ordinarily) and their mutual repulsion prevents any more electrons from coming out of the filament.

The magnetron differs from the motor in two important respects:

1. The motion of the electrons is resistanceless and nearly inertialess, so that the back e. m. f. is established instantly when the voltage is applied, and is exactly equal to the applied voltage.

2. There is a critical value of magnetic field below which the back e. m. f. in the magnetron cannot equal

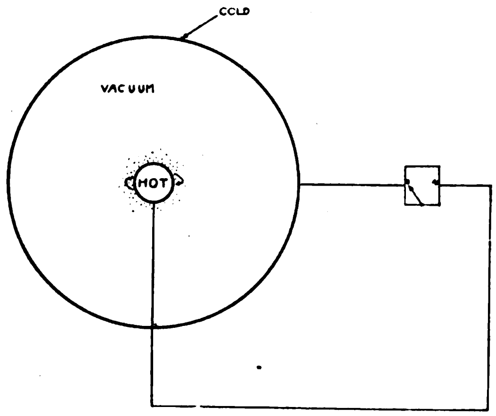

FIG. 18

a given impressed e. m. f., and the valve will not close. For all fields stronger than this critical value, it will close. This critical field is a function of the voltage, and is given by the very simple formula

$$H = \frac{\sqrt{8 \frac{m}{e} V}}{R}$$

or, putting in numerical values for m and e, the mass and charge of the electron, and expressing V, the potential across the tube, in volts, R, the radius of the external anode, in cm., and magnetic field H in lines per cm.[2],

$$H = \frac{6.72}{R} \sqrt{V}$$

Comparison of the Magnetron with other "Trons"

I have called the magnetron a *new* electric valve, for its predecessors, the kenotron rectifier, pliotron, and dynatron are all valves, each one operating on an entirely different principle and with different characteristics. The magnetron thus represents the fourth independent method of controlling the flow of current between metal electrodes in vacuum.

The *kenotron rectifier* exemplifies the control of current from one metal electrode in vacuum to another by the *temperature* of the electrodes. Electrons can pass freely from one atom to another inside a metal, so that the smallest electromotive force that can be applied is sufficient to produce a definite current. When

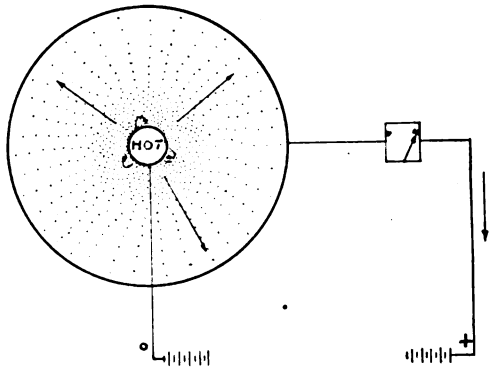

FIG. 19

they come to the boundary of the metal, however, and attempt to jump out into vacuum, they are held back by the attraction of the positive nuclei of the atoms, and can be pulled away only by enormous electric fields, of the order of one million volts per centimeter. A well evacuated tube, containing well rounded cold electrodes one centimeter apart, is thus a perfect insulator for voltages up to approximately one million volts.

When one of the electrodes is heated, however, the kinetic energy of both atoms and electrons is increased, and when sufficiently hot some of the electrons are able to jump out or evaporate, exactly as molecules evaporate from a liquid or solid. I have attempted to illustrate this in Figs. 18 and 19. The evaporating electrons drift across the vacuum to the other electrode, and constitute a unidirectional current. The rate of drift is slow, however, and they get in each

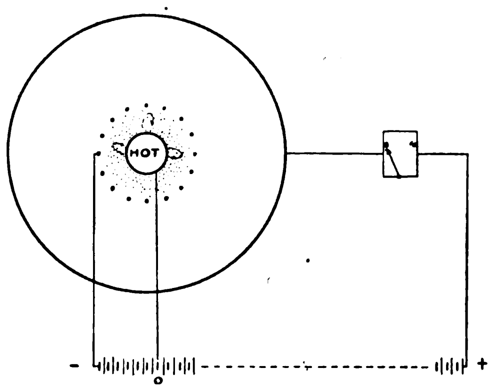

FIG. 20

other's way and cause back pressure, so that the current is very small unless they are aided by an electric field. When once out, their motion may be greatly speeded up by an electric field, and the current thus increased, precisely as evaporation of a liquid is in-

creased by blowing away the vapor as fast as it is formed. Fig. 18 is intended to illustrate crudely the case of no electric field, *i. e.*, when cathode and anode are at the same potential, and Fig. 19 the case when the anode is at positive potential.

Most metals cannot be heated hot enough, without melting, to give an evaporation or "emission" of more than a few milliamperes per square centimeter. Tungsten, however, gives an emission of hundreds of amperes per sq. cm. at its melting point, and a large filament will run for years at a temperature that gives an emission of 1 amp. per cm.^{2}, or 10,000 amperes per square meter of filament surface. For example, a filament one-quarter inch in diameter and four ft. long will operate continuously for years with an emission of 225 amperes, and will operate intermittently with an emission of several thousand amperes. It is thus evident that the kenotron is capable of rectifying very large currents at high voltages.

The rate of evaporation of liquid may be limited either by its temperature or the wind velocity, according to whether or not the molecules are blown away as fast as they evaporate. In the same way the evaporation of electrons may be limited by temperature or voltage, according to whether or not the voltage is able to carry them away as fast as they evaporate. When they are not carried away as fast as they jump out, they pile up in the space around the hot filament and produce a back pressure on those that are trying to follow, forcing them back into the filament. This condition is generally referred to as "space charge limitation"; *i. e.*, limitation of the current of oncoming electrons by the electrostatic repulsion of the electrons present in the space between the electrodes.

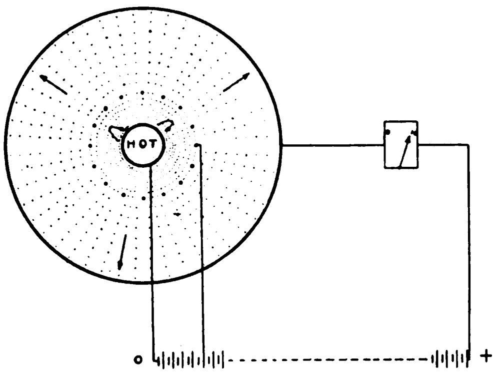

Fig. 21

I have emphasized the idea of *space charge* because it is the principle of operation of the *pliotron*,—the second method of control. In the pliotron the current that can flow from a hot filament to a cold anode is controlled by a grid interposed between filament and plate. The grid acts as an electrostatic screen, shielding the filament from the positively charged anode. The filament temperature is maintained high, so that the current is limited only by space charge, and the space charge limitation is determined by the potential of the grid.

This is roughly illustrated by Figs. 20 and 21. In Fig. 20 the grid is at a negative potential with respect to the filament, and repels the electrons so that they pile up around the filament and prevent any current flow. The valve is closed. In Fig. 21 the grid is positive, and pulls the evaporating electrons away at a sufficient rate to give a large current. The valve is open. Although it is the grid potential that pulls the electrons away from the filament, most of them go through between the grid wires to the anode, and very few strike the grid. Very little energy is, therefore, needed to open and close the valve. The pliotron is an efficient valve.

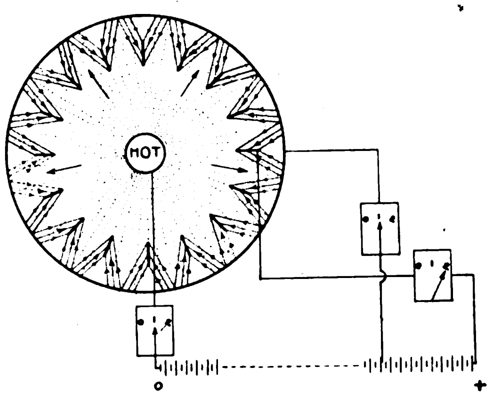

Fig. 22

The third method of control is exemplified by the *dynatron*, and illustrated in Fig. 22. I have explained that electrons cannot be pulled out of a cold metal except by very intense electric fields. They may, however, be *splashed* out by the impact of high-speed electrons on the metal. Each impinging electron may splash out from one to five or more secondary electrons, depending on the speed of impact. The secondary electrons may flow to a more positive anode (in Fig. 22 a grid) and thence through a work circuit; or power may be derived from the secondary cathode or "dynode" itself, since it has the characteristic of a

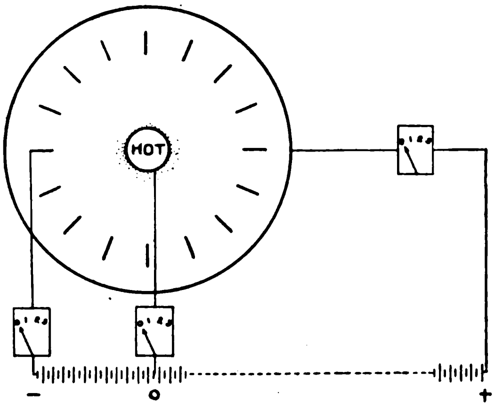

Fig. 23

negative resistance.[1] The production of secondary electrons may be controlled by varying the number and speed of the impinging electrons, and thus the dynatron valve may be opened or closed to any desired degree. The impact excitation of electrons has the advantage over temperature in that it may be turned on or off instantly, while time is required to heat or cool a filament.

The fourth method of control is exemplified by the *magnetron*, as illustrated by Figs. 15 and 16. The

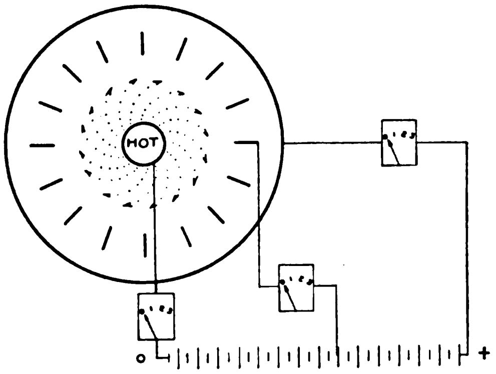

Fig. 24

electrons try to fly straight across from filament to anode. Since they are moving in a magnetic field, they are acted on by a mechanical force equal, in direction and magnitude, to the vector product of their velocity and the magnetic field. This causes them to move in curved paths as shown in Fig. 15. They all strike the anode, in spite of the curvature, as long as the magnetic field strength is below a certain critical value, as in Fig. 15. The valve is wide open. If the magnetic field is above this critical value as in Fig. 16, none of them strike. The valve is closed.

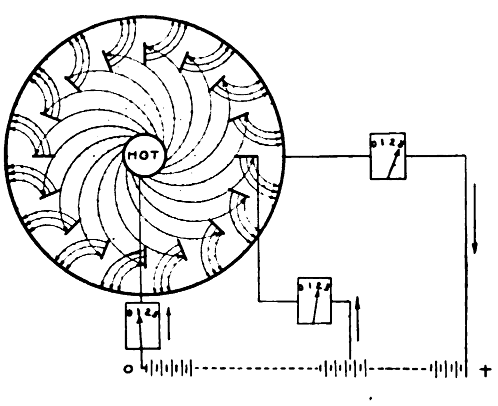

Fig. 25

These four methods of control of current flow in vacuum may be summarized by saying that two of them have to do with getting the electrons out of the metal into vacuum, by *boiling* and *splashing* respectively; the other two with controlling their flow after they are out, by means of *back e. m. f. produced electrostatically and electromagnetically* respectively.

These different methods of control may be combined in the same tube in many different ways. An example is given in Figs. 23, 24 and 25. A work circuit is to be assumed connected externally between grid and anode, and a uniform magnetic field at right angles to the plane of the figure. In Fig. 23 the filament is hot; that is, the primary valve is open; but the electrons are prevented from escaping by the back e. m. f., due to the negative potential impressed on the grid. In Fig. 24 the grid is positive, trying to drag the electrons from the filament, but they are prevented from getting as far as the grid by the back e. m. f., due to their motion in the magnetic field. In Fig. 25 the grid is sufficiently positive so that all the electrons strike it in spite of the magnetic field. These electrons are stopped by the grid. If they strike it with low velocity, that is, if the grid is only a few volts positive, they will produce very few secondary electrons, and hence very little current will flow to the anode. The valve will still be closed. In Fig. 25 the grid potential is assumed to be sufficiently positive so that the impact

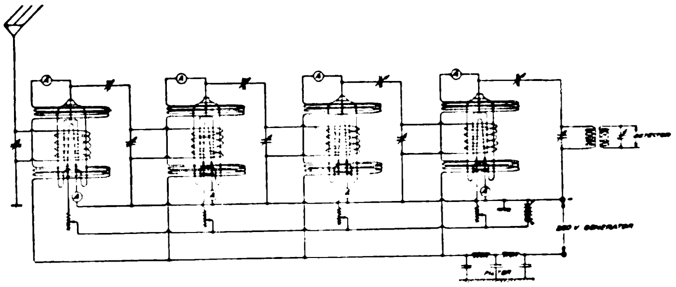

Fig. 26

of the primary electrons on it gives rise to a large number of secondary electrons. These are free to flow across to the anode and thence through the work circuit. The valve is open. It should be noted that, in order to open this valve, all four controls must be open at once—any one of them is sufficient to close the valve.

Applications

In conclusion I will say just a word about applications. The magnetron is so young that its applications are mostly hopes. The only purpose for which it is actually being used is as "synchronous detector" in continuous wave radio telegraphy, in the transoceanic receiving stations of the Radio Corporation.[2] In this case the magnetron acts as a simple high-frequency valve, opened and closed at approximately signal frequency by a locally generated magnetic field, letting

1. For description of the dynatron see *Proc.* Inst. Radio Eng., Vol. 6, pp. 5-36, Feb. 1918.

2. The synchronous detector will be described eleswhere by its inventor, Mr. E. F. W. Alexanderson.

through first the positive peaks of the signal and then the negative, giving an audible tone.

We have experimented with magnetrons as amplifiers, the current to be amplified being used to energize the magnetic field, and the output circuit being in series with the tube and battery. The operation is about the same as that of the pliotron, and the degree of amplification about the same. In a four-tube radio frequency amplifier we obtained fivefold current amplification per stage The circuit is shown in Fig. 26. In these tests the magnetrons used somewhat larger currents than pliotrons, but this is a question of tube and circuit development. The two methods of control are very similar, the pliotron utilizing for control the potential difference at the terminals of a coil, the magnetron the magnetic field of the same coil; and it appears that the amount of control obtained is about the same in the two cases.

We have also made tests with magnetrons as generators of high-frequency alternating current. The

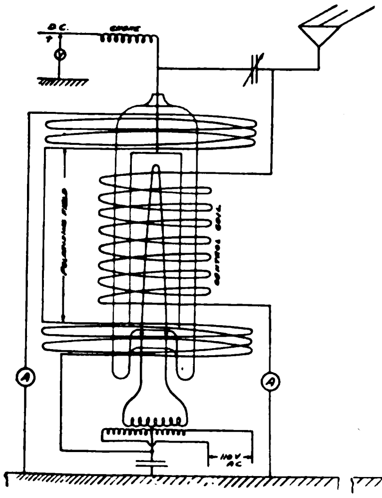

FIG. 27

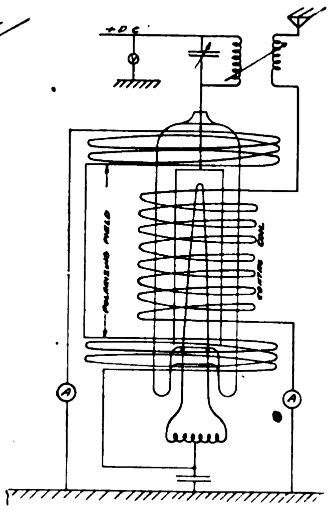

FIG. 28

tube shown in Fig. 1, which has an anode 4 in. in diameter by 12 in. long, has been operated with an output of 5 kw. of high-frequency power, and is capable, with proper development of the circuit, of 25 kw. output. The circuits used are shown in Figs. 27 and 28.

It is thus possible that the magnetron will find applications in the radio field. It has the advantage of cheap construction, and of separating the input and output circuits. Its most probable service in this field is in combination with other methods of control. The tube shown in Figs. 23-25 is by far the most efficient oscillator we have tried.

The field of radio is insignificant, however, compared with that of engineering, and it is in engineering that vacuum tubes will find their most important applications.

One of these applications is the use of magnetrons as lightning and surge arresters. The magnetron is connected in multiple with the machine to be protected, and the magnetic field is adjusted so that no current flows through the magnetron under normal conditions. If the voltage rises above normal, however, as soon as it reaches a definite predetermined excess the magnetron valve opens wide, allowing very large current to flow, but closes again as soon as the voltage falls below this same value. The time lag in the tube is nearly zero, manifold smaller than in the sphere gap, and the magnetron may find applications where this speed is important. Fig. 29 shows a simple application in which a magnetron is used to protect a high-voltage d-c. line.

I have pointed out some of the applications for which the magnetron is especially adapted. There are many other applications for which vacuum tubes

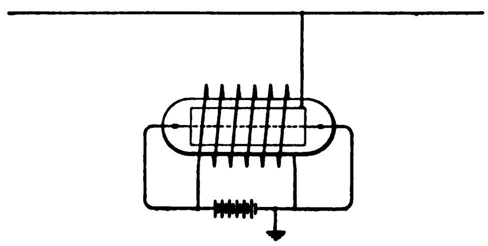

FIG. 29

are suitable, and for which one may confidently predict they will be used. Their capacity is ample. The tube shown in Fig. 1 is capable, with larger filament and water cooling, of handling hundreds of amperes at almost any voltage used in engineering. One may predict that one year will see these tubes in use as kenotron rectifiers for series arc lighting. Five years will see them in substations replacing synchronous converters. In ten years they will be on electric locomotives, either as rectifiers, allowing the use of d-c. motors, or as variable frequency alternators, taking their power from a high-tension d-c. trolley line. Twenty years will see d-c. transmission lines, fed through transformers and kenotrons, at any convenient points, by alternators of any frequency, and tapped by the same tubes acting as magnetron alternators, or some equivalent pliotron or combination vacuum-tube alternator.

The power capacity of tubes is ample for these purposes. Electron devices are not small inherently; they are only young.

Turbine Reduction Gears Versus Electric Propulsion for Ships

BY ESKIL BERG

General Electric Company

The question of whether electric or geared propulsion should be used depends entirely upon the type and operating conditions of the vessel. The Navy Department after years of comparative study, and having actual operating data on electrically propelled vessels available, has decided to equip all the larger Navy vessels with electric drive. In this type of ship, electric drive has a decided advantage, as economical cruising speed (which is so important for this type) can be obtained, the machinery can be located in the most convenient place farthest removed from disturbances from gun fire or torpedoes, plurality of generating units can be used so that damage to one or more parts will not disable the vessel, and maneuvering can be accomplished more quickly and accurately, etc.

Geared turbine drive has an advantage in fast destroyers and light cruisers. In this type of vessel, the power is generally large and the propeller speed very high—factors which make ideal gear conditions. Geared turbines can here be built very much lighter than electric drive and, as the weight of propelling machinery in this type of vessel is of utmost importance, electric drive being heavier cannot be considered.

In merchant ships each individual case must be studied, and here the questions of service, economy, reliability, weight and cost must be taken into consideration.

For fast passenger liners, electric drive has an advantage. The transmission efficiency can be made practically equal to a conservatively proportioned double-reduction gearing. It has, also, the advantage that the more efficient turbine can be built.

If two generating units are used, one unit will propel the vessel at about three-quarters speed with only slight sacrifice of economy. Noise, so objectionable in passenger vessels, is practically eliminated with electric drive.

In moderate-power twin-screw ships of about 6000 to 8000 h. p., electric drive has a decided advantage both in economy, weight and price, if one turbo-generating unit is used to drive both propellers. In case this unit, or any of its auxiliaries, should become disabled, a simple arrangement can easily be made by which the ship could be run at low speed from the auxiliary generating unit which normally drives the electrically driven auxiliaries.

On the other hand, if two generating units are used, the equipment becomes slightly less efficient, the weight and cost also go up considerably, and the comparison then becomes similar to a 3000-h. p. single-screw freighter.

Low-speed single-screw freighters, 2500–3000 h. p.: Here the geared turbine is somewhat lighter. The actual transmission efficiency of the gears is also better. However, when the losses of the reversing turbine, power taken by the oiling system, packing losses, as well as leakage of steam due to larger clearances, are taken into consideration, the transmission efficiency is practically equal to—if anything in favor of electric drive. If, however, the motor is located aft, doing away with long shafting with its expensive bearings, supports and shaft alleys, the electric drive is the lightest, cheapest and most economical, as well as the most reliable method to use. With the main auxiliaries driven electrically, the ship can by very simple arrangement be run home by power supplied from these auxiliary units, should the main propelling machinery or its auxiliaries become disabled.

In freighters of 1500 h. p. or less, geared turbines are lighter and cheaper. As the power is small, a gear can be designed which is less affected by sudden load variation or disalignment caused by springing of the hull or inaccurate workmanship.

THE modern steam turbine when considered simply as a prime mover has demonstrated its superiority in both efficiency and economy as compared with the reciprocating steam engine. The problem confronting marine engineers today is that of selecting the best methods of applying the steam turbine to ship propulsion in a way that will secure the highest over-all efficiency for both the prime mover and propeller.

Three general methods by which this is accomplished will be discussed in detail, but can be briefly outlined as follows:

(1) The turbine directly connected to the propeller shaft. This method involves a serious sacrifice in the efficiency of both turbine and propellers, as the former must be operated a speed greatly below its point of best economy and the latter must be operated at a speed greatly in excess of that which will give a maximum propeller efficiency. This compromise method of direct connection between inherently high-speed and low-speed units, despite the attractive feature of its apparent simplicity, results in such low over-all efficiency that, except in special cases, it is not now seriously considered as a feasible method by designing engineers.

(2) Interposing a gear train between turbine and propeller. This method permits both the prime mover and the propeller to operate at efficient speeds but involves the design and construction of single- or multiple-reduction gears which must withstand continuous operation under severe service conditions. It also necessitates a separate turbine element for reverse operation of the propeller.

(3) The third method, in place of the mechanical gears, interposes what might be called an electrical gear between the turbine and the propeller. In this case the turbine is designed so as to secure the highest efficiency in the operation of an electric generator, and the driving motor, which is direct connected to the propeller, is in turn designed solely for that service. All reversing is done without reversing the turbine.

Presented at the Joint Meeting of the N. Y. Section of the American Institute of Electrical Engineers and the Metropolitan Section of the American Society of Mechanical Engineers, New York, N. Y., January 28, 1921.

While the first method has practically been abandoned by marine engineers for commercial ships, the second and third methods have been applied to a considerable number of ships of various tonnage ratings and speeds, and the operating records which are now available make it possible for the marine engineers to determine which methods should be applied when the service conditions are known.

Advantages of Steam Turbine over Reciprocating Engine

When steam is used as a motive fluid, the steam turbine is by far the most economical prime mover. The turbine substitutes simple rotation for the complicated mechanical functions of a reciprocating engine.

In a turbine, an expansion ratio of 400 to 1 can be obtained, the limit of expansion being entirely governed by the temperature of the cooling water; whereas, in a reciprocating engine, the limit lies in the size of the low pressure cylinder. Marine engines generally have an expansion ratio of 15 to 1, or less. The net result is, that the turbine realizes about 25 per cent more energy out of the steam than the reciprocating engine, and can do so more efficiently.

No power station on land could today afford the use of reciprocating engines for the production of power and, with the greatly increased price of fuel, their use on shipboard is bound to become less and less.

When the turbine is considered for ship propulsion, there are a few facts about this machine which must be fully understood. These may be discussed as follows:

Turbine Speed. High-speed turbines are lighter, simpler and much more efficient than low-speed turbines.

For a given horse power, there is just one speed (rev. per min.) for which the turbines can be made most efficient. If, for any reason, this speed is reduced an inferior turbine is bound to result. The great majority of turbine ships now in operation have turbine speeds entirely too low for best economy, and the net results may, in some cases, even show an economy poorer than a reciprocating engine ship. This condition has, no doubt, retarded the introduction of turbines for the propulsion of ships.

Propellers. Propellers are limited to low speed for high efficiency. Turbines cannot, therefore, be directly connected to the propeller shaft, although it has been done with great sacrifice of economy on some very fast and powerful passenger vessels, as well as fast warships and destroyers.

The *Mauretania* is probably the best example of what can be done with this arrangement. She has 4 screws and develops about 69,000 h. p. with a propeller speed of 188 rev. per min. The turbine equipment consists of two (2) high-pressure turbines and two (2) low-pressure turbines, each connected to the propeller shaft. This really makes two (2) complete turbines in the ship, each having 34,500 h. p. In order to be able to make the best turbine possible for this horse power, the speed should have been about 1400 rev. per min. instead of 188 rev. per min. The net result is that the turbine for the big *Mauretania* has an efficiency of only 62.75 per cent, which is much lower than the Curtis turbines now being used on 2500 h. p. freighters with double reduction gearing or with electric drive. Turbines of 35,000 h. p., running at 1500 rev. per min., are now in daily use, the efficiencies of which are over 80 per cent, or 27.5 per cent better than the low-speed *Mauretania* turbine.

From this it will be seen that, in order to maintain the good economy of the high-speed turbine, and at the same time make use of an efficient low-speed propeller, some form of reduction gear must be used between the turbine and the propeller. This condition is what has brought forward the mechanical reduction gear as well as the electric drive.

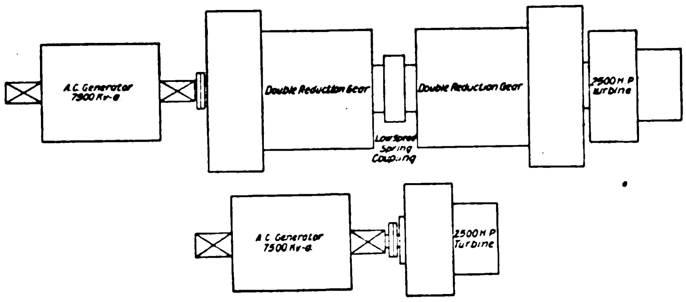

Fig. 1

Single Reduction Gears. In every case, with the exception of destroyers and light scout cruisers, the writer has found that, in order to be able to use single reduction gears, the turbine speeds have to be made too low to produce the best result, and also that a propeller speed has to be chosen which is too high for good performance. A compromise is, therefore, always necessary, and the net result is an economy less than that obtainable with either double reduction gears or electric drive. The table below gives the approximate horse powers and speeds required for the best efficiency, with turbines of the type most used for ship propulsion, and any reduction of these speeds will handicap the turbine.

H. P.	Speed		H. P.	Speed	
1000	8000	rev. per min.	10,000	2550	rev. per min.
2000	5700	"	12,000	2330	"
3000	5160	"	15,000	2090	"
4000	4030	"	18,000	1900	"
5000	3600	"	20,000	1800	"
7000	3040	"			

This table also shows that, even with double reduction, gears of the types now used give turbine speeds which are lower than those suitable for best results.

Losses in Gear Drive. These losses consist of losses in the gears themselves as well as turbine losses.

Efficiency of Gears. Most careful tests have been

made by the G. E. Company to determine the efficiency of the type of double-reduction ship gearing which it is using. These tests were made in its testing room under perfect operating conditions. The gears had perfect alignment, ran practically noiselessly, and everything was favorable to obtaining high efficiency. The tests were made by connecting two ship gears together, having the turbine on one end and a high-speed generator on the other. Fig. 1 shows the arrangement diagrammatically. After these tests had been run under varying speed and load conditions, the gears were removed and the turbine was connected directly to the same generator.

A comparison of these tests gave the gear losses of the two ship gears and, as these losses were twice that of one gear, they could be accurately measured. The result of these tests is given in Fig. 2. On this curve 1540 h. p. corresponds to what would, by present standards, be considered conservative tooth pressure

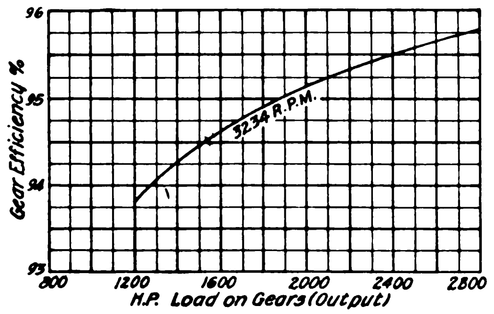

Fig. 2

for long life of the gears. The efficiency at this point is 94½ per cent.

Tests made in similar manner on single reduction gears, but of smaller capacity, indicate that for a conservative design, with such speeds as would generally be required in ship work, an efficiency of 97 per cent to 97.5 per cent may be expected. This gain in efficiency over double reduction is, however, lost in the turbine as it must be designed for lower speed.

The result of all the gear tests made shows that, low peripheral speed and high tooth pressure give the best efficiency and the efficiency falls off rather rapidly with increased speed and lower tooth pressure.

Loss in Reversing Turbine. The friction loss of the reversing turbine depends, of course, upon the design and the degree of reversing torque desired. Tests have been made in Schenectady on the reversing turbine of a 2500-h. p. ship. This reversing element gives full-load torque at stand-still, has two (2) stages and is specially proportioned to give low rotation loss.

The tests were made by driving the reversing wheels alone in a vacuum with a high-speed synchronous motor. With 28 in. vacuum and with highly superheated steam in the casing (about 300 deg. superheat) this loss amounted to 28 h. p. In actual operation one of the reversing wheels runs in contact with steam which is kept in motion by the forward turbine and which carries about 12 to 15 per cent moisture. This condition greatly increases the rotation loss, and a conservative estimate of the rotation loss of the reversing wheels during actual operation would be 44 h. p., or 1.76 per cent loss. If, for any reason, the vacuum should be impaired, this loss increases practically as the absolute back pressure and, in tests actually made, we have found that, with 20 in. vacuum and normal speed of the turbine, the buckets of the reversing wheels turn blue with heat.

Heat Variation While Reversing. In the act of reversal, work is done upon the steam before it can begin to do work, and this work all goes into superheat. This work comes from motion against the force of the steam, this motion being the result of momentum of parts and the effect of the water to keep the propeller going in its original direction. That this superheating, under some conditions, reaches a very high temperature is now well known and many turbine failures can be directly attributed to this cause.

If, for any reason, backing is done for any length of time, when an order for "forward" is received, these same heat variations occur in the main forward turbine during these great heat variations the turbine casing, as well as the moving parts, are bound to move in relation to each other and thus large clearances are required, which tend toward lower efficiency of the turbine.

Transmission Efficiency of Gears. From the above it will be seen that the efficiency of a conservatively designed, double reduction gearing is about 94½ per cent; also that the loss incident to the reversing turbine is about 1.76 per cent, making a total loss of 7.26 per cent. Besides, there is a loss in efficiency of the turbine itself due to the necessity of larger clearances and the fact that the reversing turbine makes the turbine longer, which means larger shaft and greater leakage loss between diaphragms, as well as increased packing and bearing losses. To this should be added the power taken by the various pumps required for the oiling system.

If the turbine for any reason is split up into two casings (high and low), there are additional packing losses as well as loss during transfer of steam from one turbine to the other. This latter loss is large and may amount to 2 per cent or 3 per cent.

Life of Gears. During the war several hundred geared turbine ships were built. Some were of single-reduction type with a single turbine; others had the turbine split up into two casings (high and low). The majority of ships however, in order to obtain an efficient turbine, were equipped with double reduction gearing. Here again the turbine was built either in one casing, or split up into two casings.

A few of these gears have given excellent results particularly those employed on war ships, where maximum power is only used on rare occasions. In the

merchant marine there is also quite a number of geared turbine ships giving successful operation. There has, however, been a great number of very serious gear failures. In many cases similar equipment in similar ships would give entirely different results in regard to life of the gears.

With the experience and knowledge now acquired there is no doubt that some of the early gears were entirely too small to stand the great fluctuating load which takes place due to the variation of propeller torque in heavy seaway, as well as the excessive load on the gears caused by any misalignment due to distortion of the hull in heavy seaway, which would change the load distribution of the gears.

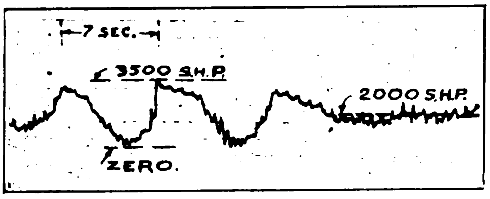

Fig. 3—Record from Torsion Spring Coupling on S. S. *Jebson* in Ballast in a Moderately Rough Sea. Average rev. per min. 78. Average shaft h. p. about 2000. Part of the smaller fluctuations shown came from an untrue collar in the instrument, otherwise record is correct.

Variation of Propeller Torque. A torsion spring coupling was applied to the S. S. *Jebsen* when running in ballast. The average horse power was 2000 and the propeller rev. per min. 78. In a moderate sea, with the ship pitching only 4 degrees, the load varied every 7 seconds from 0 to 3500 h. p. This variation of horse power no doubt is caused by the high flywheel effect of the rotating parts of the turbine and gears, which prevents the slowing down or speeding up of the propeller to follow the large load variations on the propeller while in heavy seaway.

Knowing the inertia of the turbine and the gears, a load variation, as shown in Fig. 3, would indicate that the propeller speed varied from 74 to 82 rev. per min., with a mean of 78 rev. per min. every 7 sec.

Distortion. Recently, on a 2500 h. p. gear casing which measures about 10 in. by 11 ft., a light thrust beam was pivoted and multiplying devices arranged by which any movement of the corner of the gear casing with relation to the ends of the arm could be noted. Readings were taken under different conditions of sea and wind. Under one condition of heavy quartering sea, the starboard after corner of the gear casing had an apparent movement, of which the amplitude of relative motion showed 0.05 of an inch. At times the relative motion was somewhat of a vibratory character, being affected by the tremors of the ships.

While these relative movements may, in part. have been caused by springing effect of the gear cover which supported the arm, nevertheless the movement must have affected the alignment and load distribution of the gears and may account for the large excess pressures which seem to be indicated by the performances of many ship gears.

Electric Drive

Electric transmission affords a simple and practical means of speed reduction in almost any ratio which may be desired.

Reversal. It affords means of reversal by simple change of electrical connections without changing the direction of rotation of the turbine.

Reversing Torque. Any desired reversing torque up to the full power of the turbine can be obtained without affecting the efficiency of the equipment in forward direction.

Power Measurement. Electric drive makes it possible to obtain accurate data, either by instantaneous reading or by recording instruments, of the load on the propeller shaft under various conditions of sea and wind. It also gives means by which the total horse power-hours are recorded during any given time or journey. By comparing these data with the fuel consumption a direct check can be obtained as to economy.

Noise. Electrically driven vessels are practically noiseless, whereas with gears there is always bound to be considerable noise.

Maintenance. Electrification of factories, locomotives and large rolling mills has reduced the maintenance cost to only a fraction of what it was before such electrification was made. Experience in this respect on the electrically propelled ships built in this country has also proved that the up-keep so far has been practically nil.

Economical Cruising Speeds. In warships or other vessels which need to operate economically at reduced speeds, electric drive affords means by which the ratio of speed reduction may be changed by simple electrical connections; thus making possible the economical use of the same apparatus both under high speed and reduced speed.

Interchangeability. Electric drive makes it possible to use a plurality of generating units so that damage to one or more parts will not disable the vessel.

Economy at Reduced Speed. In many of the fast passenger vessels it may be desirable to run at lower speed during certain seasons of the year. With electric drive, where two or more generating units are used, one or more of these can be shut down with all its auxiliaries and an economy can be obtained at reduced speed almost equal to that at maximum speed.

High Steam Pressure and Superheat. With electric drive, full advantage can be taken, without risk, of the increased economy afforded by high steam pressure and superheat, since the turbine itself is never reversed.

Design of Turbine. The turbine for electric transmission can be built for better efficiency. Since no reversing wheels are required, the turbine becomes shorter, which gives a smaller shaft, less packing leakage

and less weight which reduces bearing loss. Since there are no heat distortions during reversal, smaller clearances can be used. The turbine is built in one casing. Thus the packing and other losses incident to splitting the turbine up into two or more casings are avoided.

Location of Apparatus. Electric drive in many cases may afford another important advantage, namely; that the generating unit, or units, can be placed in any convenient place near the boilers, with their condensers mounted directly under the turbine, thus reducing the steam and exhaust piping to a minimum and diminishing chances of air leaks so detrimental to good vacuum condition. The propelling motors can be placed near the propellers, thus eliminating long, expensive shafting, and the bearing losses incident to the same, and shaft alleys, thus saving hold space and making cargo handling very much more convenient.

Auxiliaries. With electric drive, a great many of the main auxiliaries can advantageously be electrically driven and this affords a large saving in fuel. In case of any trouble with any of the main propelling machinery, or condensing equipment, arrangements can very easily be made by which the ship can be propelled at reduced speed from the auxiliary power circuit. This feature should be valuable for single-screw vessels.

Reliability. The simplicity and reliability of the electric motor are too well known to need further comment. It is doubtful if anything so reliable has ever before been used to drive a ship. The Navy Department, after most careful co nparative study, has adopted electric propulsion for all of our large naval vessels. The Shipping Board is, at the present time, replacing twelve 3000-h. p. geared ship equipments with electric drive. The first ship, the *Eclipse*, of about 11,900 tons, has successfully finished her trial trip and is now on her way to the East Indies. On her trip from New York to Gibraltar she beat the record of similar ships by two days (about 15 per cent) and reported everything running finely and most satisfactory.

Weight. It is very hard to give a direct comparison of weights between electric drive and geared drive as it all depends upon the type and service of vessels. For destroyers, light, high-power cruisers, or fast pleasure yachts, the geared turbine is very much lighter. In high-speed passenger vessels, the turbine and the gears themselves may be slightly lighter than electric drive but, when the steam and exhaust piping and oiling system are taken into account, the difference in weight is so very slight that it cannot be of any consequence.

The weight of the electric propelling equipment alone of the Collier *Jupiter* (7000 h. p., twin screw) is 156 tons; the weight of the geared equipment on the *Neptune*, sister ship, is 150 tons. When the piping, oiling system, etc., are added the *Jupiter* equipment is lighter.

In low-speed freighters of about 2500 or 3000 h. p., a conservative gear design of double reduction type with single-unit turbine, as built by the General Electric Company, weighs, including oiling system, about nine (9) tons less than electric drive. If, however, with electric drive, the motors are put aft, where they really belong, the saving in weight of shaft, bearing supports, shaft alleys, etc., makes the electric drive very much lighter.

As compared with reciprocating engines, the electric drive weighs only about 40 per cent of the engine.

Cost. While the electric drive may in itself be slightly more costly than geared turbine drive, the saving incident to piping, foundations, shafting, shaft alleys, oiling system, etc., makes it in many cases by far the cheaper.

Efficiency of Transmission with Electric Drive. The propelling equipment of the S. S. *Cuba* (17 knots, 3000 shaft h. p., 100 rev. per min. passenger boat) had a most complete test at the factory. The motor showed an efficiency of 95.65 per cent, including excitation, and the generator gave an efficiency of 96.3 per cent. The transmission loss is, therefore, 7.89 per cent. The cable loss is about 0.04 per cent, making a total loss of 7.93 per cent. This figure compares with gear 7.26 per cent, the difference being only 0.67 of one per cent in favor of gearing. With increasing horse power, the efficiency of the generators and motors becomes better and, in machinery designed for certain high power ships, the efficiency reaches 94 per cent.

Superheat. The introduction of high-speed turbines driving electric generators, with high degrees of superheat, has enormously reduced the cost of power for all purposes on shore. In fact, no power plant could today afford to run without superheat. On board ships, improvement in economy in the engine and boiler rooms is several times as important as in power stations, for ships must not only buy their fuel at prices prevailing in various parts of the world, but must carry it for long distances, thus displacing useful freight carrying capacity. While the use of high degrees of superheat on board ships in this country has, up to the present time, made little headway, the introduction of electric drive should greatly hasten this great advance toward fuel economy.

Performance. Following is a list of electrically propelled vessels, the machinery for which was built by the General Electric Company.

Chicago Fire Boats. Two of these boats were equipped with electric propulsion in 1908. They are twin screw boats of 500 h. p. capacity. The performance of these boats has been excellent from the start. Up to the present time no repairs to the equipment have been necessary.

Collier Jupiter. The *Jupiter* has a displacement of 20,000 tons and is a twin-screw boat. On her official 48-hr. trial, she developed 7160 h. p. and maintained a speed of 15 knots (one knot over guarantees). She has been in continuous operation since February, 1914, during which time she has seen the hardest kind of service. She holds the record in the matter of fuel economy as well as of mileage covered during this period. As to her performance and upkeep, Rear-Admiral C. W. Dyson expresses it as follows:

> It is hard to imagine any installation of machinery which could have been more satisfactory than that on board the *Jupiter*. Her repair bills are practically nil, we never receive any adverse reports or criticisms from her, and so far as appeals for navy yard assistance are concerned, we do not know that the ship is in existence. In my opinion, electric propelling machinery is on its way as the peer of all propelling machinery, and I expect to see a wide spread in its use in the near future.

New Mexico. The *New Mexico* has a displacement of 32,000 tons and belongs to our latest and largest class of battleships. She is a four-screw ship and at maximum speed develops 32,500 h. p. She has been in operation over two years, during which time there has never been trouble of any kind with the electrical equipment. During the gun trials when all the twelve 14-in. guns were fired broadside, there was not a loose wire, cable or broken insulation to be found.

The fuel economy of the *New Mexico* came up to expectations. In *Marine Engineering* of May, 1920, there was a most interesting article entitled "Two Years of Electric Propulsion on the *New Mexico*" by Commander S. M. Robinson, Fleet Engineer of the Pacific Fleet, of which the *New Mexico* is the flag ship. He compares it with the *Idaho* and *Mississippi* which are sister ships of the *New Mexico*. The *Idaho* and *Mississippi* have direct connected turbines but with geared cruising turbines (the *Idaho* having Parsons turbine, and the *Mississippi* Curtis). The *Idaho* can use her geared cruising turbines up to 17 knots and the *Mississippi* up to 15 knots.

The table below gives a comparison of the fuel economy.

At	10 knots	the *Idaho* and *Mississippi* consume about	20%	more fuel
"	13 "	" " " " " "	42.7%	" "
"	16 "	" " " " " "	47.8%	" "
"	19 "	" " " " " "	40.1%	" "
"	full power	" " " " " "	32.0%	" "

The *New Mexico* has also been awarded the highest merit in engineering for the year of any battleship.

S. S. Eclipse. The *Eclipse* is a freighter of 11,868 dead weight tons; 440 ft. long; 56 ft. beam; belonging to the United States Shipping Board. She was originally equipped with geared turbines which were removed and electric drive was substituted. She is a single-screw vessel of 3000 brake horse power, and is equipped with one (1) turbo-generator supplying power to a 3000-h. p. 100-rev. per min. induction motor. All her trials were eminently successful and she is at the present time on her maiden trip to Singapore and Java with full cargo. A cable received from Gibraltar states that she broke the record of similar ships to Gibraltar by two days. The arrangement of the auxiliary steam is very wasteful, several hundred horse power being wasted. Still, unofficial figures indicate that, although making higher speed, the fuel consumption is less per day than before.

Cuba. The *Cuba* is a passenger vessel of about 4000 tons and 3000 shaft horse power. She is equipped with one turbo generator and the propeller is driven by a 3000 shaft horse power synchronous motor, running at 100 rev. per min. As she was the first synchronous motor ship, her trials as to maneuvering and reversing were most extensive and proved most satisfactory. In fact, reversing from full speed forward to reverse was done too quickly to suit the captain and chief engineer, and changes in control were made to accomplish this reversal in a little longer time. The ship makes between 17 and 18 knots and is at the present time in regular passenger service between Jacksonville, Fla., and Havana, Cuba.

No records as to fuel consumption are as yet available.

The following is a list of electric propelling machinery now being built by the General Electric Company:

For the Navy.

3 battle-ships	*California* *Maryland* *West Virginia*	each 32,000 h. p.—total	96,000 h. p.
2 battle-ships	*Iowa* *Massachusetts* *Constitution*	" 60,000 h. p.— "	120,000 h. p.
4 battle cruisers	*United States* *Saratoga* *Lexington*	" 180,000 h. p.— "	720,000 h. p.
		Total—	936,000 h. p.

For Merchant Marine.

11—3000-h. p. freighters similar to the *Eclipse*	33,000 h. p.
4—2600-h. p. coast guard cutters, synchronous motor	10,400 h. p.
1—3000-h. p. United Fruit Company	3,000 h. p.
Total	46,400 h. p

MANUFACTURE OF ELECTRICAL EQUIPMENT IN AUSTRALIA

With the growing interest in the use of electrical equipment and appliances in Australia, involving many new schemes for the employment of electric power in place of coal for motive and railway uses, new plants for the manufacture of electrical goods are being erected, writes Vice Counsul Ray Fox from Melbourne. He also states that the Victorian Railway Commission, which operates the Government-owned railroads of the State, is gradually electrifying the railway system of Melbourne and surrounding suburbs the entire system being scheduled for completion by 1923 and calling for large orders of electrical equipment.—*Commerce Reports.*

The College Trained Engineer

Suggestions for Improvement

BY C. EDWARD MAGNUSSON

Chairman, Educational Committee, A. I. E. E.

IN the annual report (1921) of the Educational Committee to the Board of Directors reference is made to a circular letter which was sent to a hundred prominent electrical engineers, requesting constructive suggestions for improvement in the training of engineering students in our technical schools and colleges. Three questions or topics were submitted:

1. State what is the basic thought or philosophy that should be impressed on the student which will serve him best as guide in his future work.
2. Suggest a problem or problems, a better knowledge of which would help the student later to take up work in your own field.
3. Give a suggestion or two that would aid in making college training of embryo engineers more effective.

A study of the sixty-eight replies received reveals a remarkable unity of opinion. Several of the suggestions are found in a majority of the letters and many of the writers apparently hold identical views as to what is essential in the training of engineers. A valuable contribution towards a better understanding of fundamental principles in engineering education is made by Mr. B. G. Lamme, whose letter is incorporated as an important part of this report.

FIRST QUESTION

The majority of the replies to the first question may be summarized in one word—*service*. The young engineer should be governed by an earnest desire to accomplish something useful and worthwhile; to become a constructive force in the community; to be considerate of the opinions of others, and to cooperate cheerfully and unselfishly. Of the other suggestions may be mentioned "a better appreciation of the economics of engineering," "the value of health," "the importance of scientific knowledge and research," "never to cease being a student," etc.

"That service is the key-note of life. Service is based on work and the philosophy applies to students as well as to those with whom the student comes in contact."—R. W. E. MOORE.

"A definite choice of his engineering environment with a selection of the essential feature he desires to follow. After selection of this feature an untiring effort in preparation to become a master of it should govern his procedure, with the predominant thought always in mind *to give service*........An engineer should give service at the beginning of his life but I hold that a greater individual happiness accrues to him who progressively increases service as his life is lived. In other words, there is greater wealth and greater happiness in an accumulation of service than money. Therefore, integrating all I have said regarding (1) I would say the philosophy that should be impressed upon the young engineer is that he should give service." —W. S. MURRAY.

"That *service*, in the broadest sense, is the best motive in life, and that success in rendering it should be every man's controlling principle, both in selection of a vocation and in pursuit of it."—FRANK F. FOWLE.

"The awakening of the imagination to a conception of the usefulness and scope of knowledge. To seek to know and remember the reason for a fact and not simply the fact itself."—W. L. R. EMMET.

"I can only give you from my own personal creed what I believe to be the biggest idea that any engineer can get, and that is service. To get this across to the undergraduate I believe that you should make him feel that the world is not equipped with machinery and simply waiting to carry out his ideas but that the world has a great many problems to solve and is waiting for him to help in the solving. Perhaps the appreciation of the value of a spirit of service grows with increasing years better than any other way, but I have a feeling that it can be communicated to younger men if gone about in the right manner."—A. M. DUDLEY.

"While a knowledge of engineering fundamentals is quite necessary, the supreme importance of applying just plain common sense in all problems should constantly be kept in mind. This common sense should be applied in all other affairs of life as well as in engineering and the student should learn the value of mixing with his fellows and taking a live interest and active part in affairs of citizenship."—R. F. SCHUCHARDT.

"Keep your mind always open. Never accept any working hypothesis as an indisputable or immutable law......Above all things, however, make the college really democratic and drill into the student's heads that all they obtain at college is a training in how to think and a grounding in the fundamental principles so that they are ready to start life's work. The college student who starts life's work with an idea that because he has been to a certain college of high reputation he is better than other young men who have not been to college, has a serious handicap and it takes him some years to jockey for a fresh start."—TALIAFERRO MILTON.

"By *attitude* is meant much. It combines cheerfulness, cooperation, self-helpfulness, determination and consideration for others, in a happy balanced combina-

tion which allows—the more or less—otherwise untrained to fit in, be liked, progress and get results where another of much superior understanding and training, but without attitude, completely fails. Attitude absolutely ranks ability in every normal competition. There may be lone instances where ability might excel, but never in 'team work' which in modern industry and society is almost always the invariable rule. I would much prefer that my boys should have the proper attitude and merely very ordinary ability than wonderful ability and poor attitude. Attitude is a phase of the 'make-up' demanding initial mental endowment. Fortunately, therefore, attitude can be acquired, while the capacity to demonstrate ability seems to lie with each individual."

"Obviously *health* is essential, and proper conservation and regard for the physical should be impressively and constructively emphasized. Young men are often careless and make commitments against their 'health credit' which have to be taken up later, when 'exchange' may be very unfavorable."—K. C. Randall.

"With regard to a basic philosophy, I think a college man above everything else must be taught to be honest and to have consideration for others' opinions and ideas as his progress will depend largely on his ability to get along with others. He must learn to build up and construct, helping others rather than criticise and tear down and get his reward from the cooperative effort and confidence others place in him."—G. W. Ashe.

"Instill in the minds of the students their individual or personal responsibility to their profession as engineers and citizens. Proved initiative and ability are recognized above a diploma, but a diploma gives a man a head start."—O. D. Higgins.

"At the risk of accusation of being a gross utilitarian I would state that the criterion of all engineering work in the industrial world today is 'Will it pay?' This measuring rule is a flexible one and may involve a prophetic insight of the future economic conditions; it may further involve an idealistic conception of the value of beauty of form and arrangement; or again it may be a discernment of the value of social and welfare relations in the economic life of the community. In the last analysis, however, engineering work must pay or it is futile."—L. T. Merwin.

"That greater emphasis should be placed on what may be called the economics of engineering. That is, generally speaking, engineering is only a means to an end and not the end in itself which usually has a place in the economic structure of the locality or corporate system. Its value will be measured by how efficiently it articulates with the remainder of the project and its all around economy as a part of the whole."—S. D. Sprong.

"The basic thought or philosophy which should be impressed upon the student is the value of scientific knowledge and research in our modern industrial development and the important position which the Engineer occupies in conserving and developing our natural resources for the use and advantage of mankind in a way to improve living conditions and increase the wealth of the peoples."—Wm. S. Monroe.

"Do everything possible to give the student vision, cautioning him, if you will, against the serious results of confining himself solely to a technical field of work. To be well versed technically is necessary, but he must read good literature and keep abreast of the world's affairs in matters other than technical in order to have a broader vision, so that his imagination will be developed and that he may know the problems other than in his own particular field, and from these problems may gain thoughts that will be of great benefit to him."—S. J. Lisberger.

"If some one thing is needed now to help students, it would seem to be that they should know more of the truth about themselves, particularly as to their location in the picture and as to its perspective. It is very doubtful if they generally appreciate that life is a continuous educational process and that nothing definitely separates the particular part of life that they spend in college from what went before or what is to follow. It is simply a period when it is easiest to learn certain kinds of things and coming as it does when students have little earning power, it is a very convenient time to allow them to concentrate on the accumulation of knowledge, in much the same way that kindergartens are found to be convenient for younger students. That part of their educations which they use in their professions could perhaps be obtained elsewhere and at some other period, but not so easily and not so efficiently, and that is the impelling motive for colleges. That part of a student's education which is received in college is terminated by economic reasons and not by the capacity of the student to learn or of the college to teach."—E. H. Bangs.

"Reliability. This includes probity of course. But it also includes accuracy and initiative."—
Ralph D. Mershon.

"In the main we are rather of the opinion that it would be preferable, in the engineering courses, to devote more effort to the teaching of fundamentals, such as physics, chemistry, mathematics and devote less time to the specific applications through the various branches of engineering. Also we would suggest that time be devoted during the engineering course for the consideration of some of the more broadening subjects, such, for example, as English—oral and written—history, economics, philosophy, finances, business, etc."—W. M. Skiff.

Second Question

The purpose of the second question seems to have been misunderstood and was in most cases left unanswered. The purpose of the question was to gain a goodly number of new specific problems with quanti-

tative data in accord with present day practise and of such a nature as to hold the interest of the student and give him a better appreciation of the principles involved. The problems suggested are, however, stated in such general terms that little of value is gained. Some of the suggested problems are: "The elimination of waste and the reduction of cost of operation;" "analyze the heat losses and efficiency from coal pile to switchboard in a central station;" "problem of inductive interference between power lines and communication lines;" "the production of power for the joint use of utilities, railroads and industries that will give a maximum of reliability with minimum investment and minimum operating cost;" "the economic comparison of generating, transmitting and distributing power systems as between two frequencies—say 60 and 25 cycles—involving the effects of design on cost of machinery, materials and equipment, as well as the consequence of these costs in their relation to rates and the returns due to capital;" "the problem of high potential transmission and distribution of electric energy on underground systems;" "studies incident to the advisability of developing water or steam power as the load increases;" etc. To be of service these and similar problems require comprehensive data which unfortunately are seldom available for students and instructors in technical schools.

Third Question

The question invites answers of a wide range and it is therefore significant that a majority of the replies place special emphasis on the importance of a better understanding of fundamental principles, the ability to think logically and the need for training in how to approach and solve new problems. The graduate's store of information is discounted, and to give the old type of manual training in the college is considered as largely a waste of time. The need of better training in English, mathematics and business principles is emphasized in a large percentage of the replies.

"Development of the power to think is more important than the accumulation of information, no matter how great in amount. Also that which contributes to the development and accentuation of personality through discipline and culture, sees a man further than that which contributes to the equipment of the specialist. In every profession, it is the all around men that are at the top—the men who are interested in and know other specialties besides their own."—Gano Dunn.

"In my opinion, the crime of most of the colleges today is that they do not teach their students to think. They try to cram too many concrete facts into their heads. It really doesn't matter very much whether a student learns much of a concrete nature in college provided he learns to think.

"The great majority of the time should be spent in the fundamentals. There is entirely too much time wasted in most of our technical colleges on shop practise, teaching students how to do a poor blacksmith job, how to file a flat surface, etc. The few short years in college, in my opinion, can be much better spent by drilling in the fundamental principles."—Taliaferro Milton.

"My conclusions are that the greater the concentration and thoroughness with which the embryo engineers are trained in the fundamentals and their applications, the more self-reliant they will be made for practical life. I wish it to be understood that I do not aim to make engineers theorists, but I wish to instill in them broad and sound theory at the time and place when it can be done most efficiently. My idea is that a broad knowledge of the fundamentals of all physical sciences is the most liberal education with which a future engineer may be endowed."—Philip Torchio.

"Ground them thoroughly in the fundamentals of physics and mathematics; both to be taught by engineers and not by physicists and mathematicians."—A. H. Babcock.

"More time should be spent in a very thorough grounding and understanding of the fundamentals, and less time on specialties, details, the professor's hobbies, highly advanced theoretical studies, non-essentials like Latin, Greek, literature, history, etc. A sound foundation will serve for many different superstructures with their different details, while the best of superstructure will fall if the foundation is not sound. These fundamentals will differ for different branches of engineering, but many of them overlap."—Carl Hering.

"In college I would suggest furthering the idea of thinking for himself; of seeking a logical method of approach to the problem rather than seeking an answer to the problem."—"Endeavor to develop initiative. Many good men, well educated, technically trained, and fully competent to do good work have no initiative, and as a result they become merely plodders. If initiative can be developed, and if students have the training and the personality, one of the most important factors in their work is assured."—"Clear thinking may be developed before the student enters college. Clear thinking should be impressed upon the pupil, and next impress upon him to study English, that he may express his thoughts clearly and definitely."—S. J. Lisberger.

"I feel that in the actual teaching the professors and instructors confine their activities entirely too closely to text-book matter. The fundamental principles should be taught from those text-books but I feel that problems should be given that require simple reasoning in addition to the particular laws then under discussion, as the number of college students capable of properly analyzing the problem is almost zero, and the number of graduates showing any analytical turn of mind is very small. This means that all college training should be along lines that tend to make the student's mind a reasoning mind rather than one depending on memory alone."—N. E. Funk.

"The whole field of engineering, and even now of commerce and business itself, demands analytical ability of the highest order. Therefore the capacity to analyze an unknown problem, first recognizing all the elements or variables which are present in it, and then to progress step by step in considering each factor and its bearing on the objective or result sought, is today a prime requirement for personal success in engineering and industry."—FRANK F. FOWLE.

"Do not try to turn out engineers; try to turn out men well grounded in the fundamentals of engineering. Work for quality of output, not quantity. If the colleges and universities spent less on equipment and more on maintaining the quality and numbers of their instructional forces they would achieve better results than at present."—RALPH MERSHON.

"First, there is a need for more professors who are practical engineers, who have gotten out and rubbed shoulders with the world, and who are capable of doing the job they are trying to teach their students to perform.

"Second, in order to secure practical teachers it will be necessary to compete from a monetary standpoint with the industries, and this means that we have to pay attractive salaries in the teaching profession.

"Third, there should be the closest cooperation between Industry and the Institutions of Learning, and if necessary, Industry should assist in liberally endowing them in order to make the fullest use of their facilities for research work and the development of new fields of progress. This alliance of Science and Industry brought Germany to the very pinnacle of commercial success just prior to the war.

"Fourth, no engineering course should be considered complete without requiring the student to do one year's work in some Manufacturing Establishment, or in some branch of practical engineering work allied with his own course."

It is of the utmost importance to include a limited amount of business training and legal training in the engineering curriculum. Engineers, as a class, are deficient in knowledge of these subjects.

"Above all, college spirit should tend toward democracy and not to exclusiveness. More than one college graduate has prejudiced employers toward his kind by consciously or unconsciously cultivating a slight air of exclusiveness."—H. C. HEATON.

"Ground them thoroughly in the English language,; a lack of command of which in writing and speaking is the greatest single defect in the college training of most engineers. It is not enough for an engineer to be skilled; he must make his skill prevail, and the power and culture that comes from familiarity with English are tremendous forces in the success of an engineer." —GANO DUNN.

"I am profoundly impressed with the fact that the engineering student fails generally in his grasp of the English language and in his ability to put over in a terse, concise and convincing manner the scientific and analytical problems he has in mind. This inability often leads to failure in attaining the success in life that otherwise would be possible. This ability is not acquired merely by English courses in engineering curricula, but rather by analytical practise on the part of the student himself, questioning himself as to whether he would understand the message were he the other man for whom the message is designed. It is said that Abraham Lincoln became the master mind in this regard only after long and patient practise as each instance arose in his experience."—ROBERT SIBLEY.

"A better knowledge of accounting and the ability to read a balance sheet as well as a blue print." —H. L. WALLAU.

"As far as our own work is concerned, the engineers should have a better general knowledge of business, *i. e.*, banking, the laws pertaining to contracts, accounting, and all of the many aspects of business, of which the average trained college engineer knows little or nothing."—F. C. BATES.

"During the year preceding that in which the student must select his particular branch of engineering, he ought to be given a course of lectures describing what each of the different branches of engineering comprises, that is, what kind of work he would have to do, what studies he would have to take up, what the probable field for employment is, what the possible field of development is, etc. This should embrace not only the few general branches of engineering, like electrical, mechanical, civil, mining, chemistry, architecture, etc., but should also include the subdivisions; in electrical engineering for instance, such subdivisions as the generation and distributions of power, design and construction of machinery, telegraphy and telephony, furnaces, electrochemistry, teaching, salesmanship, administration, etc. At the end of such a course the student is better able to make a correct choice, and his teacher is better able to advise him, and to sort out the wheat from the chaff. A student will always do best in that branch in which he is most interested, but he often fails to make the correct choice because at the time of making it he has too little knowledge of the kind of work and study required in the various branches."—CARL HERING.

"The college professor should keep abreast with the development of the art, first, to use live material in the illustrations not with the intent of giving actual designs, but to avoid imperfections in the theory of older designs; and second, to employ constants and experimental data up-to-date rather than older data. Either set of data would serve to explain the theory, but the students are more inspired if they know that the data comprise the last word of the art. The student should compile his own engineering notes and tables for all subjects he happens to analyze; for instance, an electrical engineering student should have tables of magnetic characteristics of electrical and

silicon iron, conductivity of copper, aluminum, iron, etc., standard tables of wires and cables electrochemical constants for all metals, thermal resistivity and electric resistivity of different insulating materials, etc."—PHILIP TORCHIO.

Mr. Lamme's letter. Special attention is called to the excellent discussion of engineering education by Mr. B. G. Lamme. Much progress would be made if all members of the teaching staffs in engineering colleges and technical schools realized that "a boy goes to college for the purpose of learning to use his head, not merely to fill it."

"In reply to your letter of February 24th, asking about improving college trained engineers, I can give some of my opinions, based upon my experience with college trained men.

"In the first place, as I think I have mentioned to you before, I find that the vast majority of technical graduates from our schools have no real grasp of fundamental principles. These principles may have been taught to them, but have gone over their heads, or they have not realized that these were fundamental. The principal reason for this lack of realization, I think, lies in the fact that the students are not trained in the use of such principles. Possibly many of them would not have the grasp even if they were trained in the *use* of fundamentals, but the general indications that I have found are that they have never been drilled in the use of the fundamental principles. I can cite several instances in my own experience which may serve to illustrate the point which I have in mind.

"In my own work in college, where I took up a course in mechanical engineering, the professor at the head of the department, S. W. Robinson, had a tremendous reputation, among the boys, as a man who knew practically everything. In other words, the general feeling was, that he was a 'wizard' in engineering matters. Naturally, hearing such things, I at first held the same opinon. However, as I got to know him better (and eventually I was very close to him in engineering matters), I acquired an entirely new opinon of him. To my surprise, I found that there were a vast number of subjects about which he apparently knew little or nothing, but, nevertheless, on such subjects he could reach conclusions quickly and reliably. For example, in endeavoring to find the source of this ability, and also how he 'got at' things, I devised, from time to time, a number of special problems, which I 'sprang' on him on suitable occasions, usually in private. On such problems I had done considerable work and had encountered some difficulty which was the occasion for presenting the matter to him. I found that in practically all cases, when I first presented such a problem to him, he knew practically no more about the subject than I did, or even possibly less, but that almost invariably, after a little study, he could solve the difficulty for me and explain it to me clearly. In getting at how he did it, I came to the realization that he simply relied upon a few fundamental principles and that he brought these to bear directly on the solution of the problems, I put up to him. In many cases I had also gone over these same fundamental principles, but had no realization to what extent they could serve as tools for handling difficult work. Gradually, in watching Professor Robinson's work, I came to the knowledge that his real strength did not come from any broad general fund of information, but rather from the fact that he had apparently a limited amount of information of a sort from which he could construct almost anything he wanted. This gave me an entirely new idea of the meaning of education. With him it was a case of having a few general-purpose tools, which he could use in all manner of ways to construct a desired result; whereas, compared with him, many so-called educated men had a vast collection of tools practically none of which they knew how to use.

"This leads to another point which I want to bring out, namely, that a very large percentage of engineering students in colleges do not realize that the mathematics, which they study, is simply a tool to be used in getting results. The study of mathematics with them is simply mathematics, and not a means to an end. It is as if one would show the students some very fine instruments or tools and explain to them the construction of such tools, their fine workmanship, etc., but would never teach them how to use the tools. It is the use of mathematics that is important. Moreover, for a vast percentage of engineering work in general, it is not the difficult mathematics that is required. Algebra, geometry and trigonometry can probably take care of 99 per cent of the high grade engineering work, but unfortunately, only a very few of the students can really handle algebra and trigonometry in particular. The fault here apparently lies with their fundamental training. The knowledge of mathematics is cumulative. In other words, each part is built up on the preceding part. If the foundation is worthless, then the upper structure is of little value, no matter how much care has been taken in it. Algebra and trigonometry should be drilled thoroughly into the lower class students until they have a handy working knowledge of them and can use them in all kinds of problems. In other words, these should become almost a form of technical language. With such a foundation the student can tackle more advanced mathematics, and advanced studies requiring mathematics with greater confidence and with a grasp of principles, as he goes along, which continually prepares him for still more difficult work. But if, the foundation is bad, then the further he goes the worse he gets.

"What I want to lead up to, is that this foundation is built up mostly in the high schools and is strengthened but little in the early years in college, and, in many cases, is an utterly worthless one. In fact, if you would question one hundred engineering students in the

freshman class in any college, I think you will find that an extremely small percentage of these have ever used algebra, geometry or trigonometry outside of class work or the book lessons. Among the hundreds of selected college men, whom we have brought to the Westinghouse Company, I have found a very large percentage who give a negative answer to the above question, as to the use of their high school mathematics outside of class work. This is almost inconceivable. In my own case (I took up algebra at thirteen) I found, shortly after beginning the study that a number of the puzzling problems in higher arithmetic could be solved quite readily by the use of algebra. I also found that some of the problems in geometry which were rather complex and difficult to explain were almost axiomatic with algebraic treatment. Occasionally I find young college graduates who have had similar experiences.

"In view of the above statements, I would say that every engineering student, during his freshman year at least, should be given a most thorough training in the more elementary mathematics, and be made to use his mathematics by means of a great variety of problems, these problems constituting the bulk of the work. Those who show a total inapitude for such work could be weeded out from the engineering classes, for if they cannot do any of the elementary mathematics they have no business to tackle the higher work. When I speak of 'elementary' mathematics, I mean what the word says. I have talked with a number of college professors on this subject and quite a number of them said that they do just about what I call attention to, that is, they give their freshman a thorough training in algebra and trigonometry. But, upon questioning them further, I have found that in many cases, instead of taking up the elementary mathematics, they have attempted to teach very advanced algebra, very advanced trigonometry, etc., which the ordinary high school graduate is totally unprepared to undertake properly. In other words, they have undertaken to build on top of the existing inferior foundation instead of rebuilding the foundation itself.

"I consider this lack of fundamental mathematical training as being one of the great evils in the engineering training in America today. How can a student have a thorough grasp of fundamental principles, unless he has sufficient mathematical knowledge to do so? For many engineering principles are physically of a mathematical nature, that is, they involve quantitative conceptions. I do not mean to give the impression that mathematics consists of mathematical formulas, for some of the very highest mathematical conceptions may simply be physical conceptions, or visualized laws or relations. Some men have very strong physical conceptions and yet are not skilled in the use of mathematical formulas. Nevertheless, if one studies such men carefully, he will find, in many cases, that their physical conceptions are really a form of mathematics, which may exhibit itself in the shape of sketches or diagrams and in various other ways, which do not appear offhand to be mathematical. The physical conception, or the visualization of a fact or principle, is of immense value in engineering work, and this is something in which the student can be trained to a considerable extent, if he has the proper foundation for it.

"A very broad-spread idea, which should be combatted, is that the boy takes a college course for the purpose of collecting information. This idea is not only a mistake but is a very harmful mistake. A boy goes to college for the purpose of learning to use his head, not merely to fill it. Much of the college training today is in the nature of a filler, and much of the filler is worthless in the way of future advantage. If the boy is to be an engineer, presumably he will want to lead in something and his future work may consist largely of things which do not yet exist. Much that he acquires at school is simply the story of what is already done, that is, it covers what is already a story of the past. The value of this past work lies mostly in the principles upon which it is based, and these principles are very liable to be carried into the future. Therefore, if the college boy can be trained to set aside the vast mass of facts and results of the past, and simply recognize a few fundamentals upon which these are based, he will be fairly well equipped for his future work.

"As an indication of how little we care for the student's knowledge as a whole, I may say that in reviewing the selected college graduates for our work here, we ask them almost nothing about their work in general. We simply endeavor to find out their aptitudes, characteristics, analytical abilities, use of mathematics and how well they can use their heads. The showing, even among these selected men, is desperately poor. In fact, I am sometimes inclined to think the case is hopeless. Perhaps the colleges are not to blame for this situation,—in some cases we are sure they are not. However, if the engineering colleges would do no more than to materially improve the elementary mathematical capabilities of the students whom they turn out, they would be doing something worth while, for with this improved training, many of the college men would apply mathematics to their more advanced studies, thus resulting in greater improvement all along the line. Training the boy to use elementary mathematics skillfully, so that he can apply this knowledge, through his own initiative, to many problems outside the class-roon, means training him to think for himself; and if he thinks for himself logically, and of his own initiative, he then has the best that a college education can give."—B. G. LAMME.

To give contrast, and to some extent historical background, to the ideas expressed above, the following letter is included, as it represents the old view of engineering education, giving an excellent summary

of the qualifications the young graduate was expected to possess and the mass of information that he was supposed to acquire during four short years in college.

"Your letter of February 23rd has received considerable thought before making reply, since the inquiries you make cover very serious phases of engineering education as well as its later application in engineering practise.

"In answering the questions which you propounded, I find it necessary to confine myself to such thoughts as I may have as directly connected with the business in which I am engaged,—*viz.*, electrical engineering in a public utility corporation.

"For this specific line of work, it is suggested that the following phases of education would contribute largely to the success of an electrical engineer.

1. A thorough grounding in the theory, design and application of electrical apparatus to commercial practise.
2. A thorough grounding in mechanical engineering.
3. A reasonably thorough knowledge of chemistry in its elementary forms.
4. A thorough knowledge of steam engineering.
5. A thorough knowledge of hydraulic engineering.
6. A thorough knowledge of mathematics and modern accounting systems.
7. A knowledge of corporation law sufficient to enable one to intelligently deal with land titles as involved in rights of way, settlement of property and personal damages as incurred in daily operations, and a full understanding of the grounds upon which decisions of public utility commissions are based in settling rate questions.
8. A thorough knowledge of the underlying principles which are fundamental in the development of rate schedules.
9. A careful development of personality such as will enable a student to handle men successfully in actual business.
10. Last but not least a full and complete knowledge of the value of money invested in business and the proper relations which must be maintained in successful business between investment, fixed charges, operating expenses, and the miscellaneous other factors such as replacement charges, reserves, etc., which go to make up the complete operations of any successful business.

"In making the above suggestions, I appreciate that they cover a very wide field, but not a wider field than is covered in the various courses of studies now pursued in our higher grade colleges.

"Trusting that this review of desired accomplishments in our coming engineers may be of interest to you, I remain," etc.—L. L. ELDEN.

It should be noted that only a few letters in favor of the old view were received while a large majority of the replies offer suggestions that are in full accord with Mr. Lamme's concept of what is essential in engineering education.

RADIO FOR SIGNAL AND DIRECTION FINDER SYSTEM DEMONSTRATED

The Bureau of Standards, in cooperation with the Bureau of Lighthouses of the Department of Commerce, has developed a system of radio direction finding, by means of which the navigator of a ship can determine his position in a few minuted, using instruments under his own control. Such a device is particularly useful in time of fog or thick weather.

The Department of Commerce system of, radio direction finding consists of two or more radio transmitting stations in fixed locations, either on shore or on moored light vessels, and a device called the radio direction finder or "radio compass" located on board ship. The transmitting stations are of one of the types usually employed for radio communication, but are designed to operate automatically. The radio direction finder, as now developed by the Bureau of Standards for use on board ship, consists of about ten turns of insulated copper wire wound upon a rotatable wooden frame about four feet square. This coil is mounted directly over and is operated from within the pilot house. When the plane of the coil is parallel to the direction from which a radio signal emanates, the intensity of the signal received will be a maximum. As the coil is revolved, the intensity of the signal diminishes until a minimum is reached when the plane of the coil comes to a position at right angles to the line of the direction from which the signal emanates.

The Bureau of Standards has installed on the Lighthouse Tender *Tulip* a radio compass of improved design, and radio transmitting stations for fog signaling service, which operate automatically, at the approaches to New York Harbor, on Ambrose Channel Light Vessel, Fire Island Light Vessel, and at Sea Girt Light Station, N. J. These three transmitting stations have been in regular commission since May 1, 1921, and are the first fog-signal stations of this kind established in this country.

A demonstration was held on June 27 and June 28 at New York, at which the three stations mentioned transmitted to the *Tulip*. Interested persons made a trip on the *Tulip* beyond Ambrose Channel Light Vessel and every one present had an opportunity to work the radio compass and take bearings. A number of bearings was taken by radio while in sight of Ambrose Channel Light Vessel, and the average error of the bearings was 1½ degrees, with a maximum error of 3 degrees. An account of the demonstration is published in the *Lighthouse Service Bulletin* for July 1, 1921.

Electricity Applied to Ship Auxiliaries

BY H. L. HIBBARD

Marine Dept., Cutler-Hammer Mfg. Co., New York, N. Y.

SINCE the first installations of electric plants on the steamship *Columbia* in 1879, consisting of two Edison bipolar dynamos with capacity of sixty 10-candle power lamps each, and the first installation in the Navy on the *U. S. S. Trenton* in 1883 consisting of one Edison bipolar generator at a rated capacity of 115 60-candle power lamps and belt driven from an Armington and Sims engine; there has been great progress during these forty years in the use of electricity aboard ship. This is particularly true when we consider naval vessels where practically every moving element now receives its motion from an electric motor, but in the adoption of this motive power on vessels of the merchant marine, progress has been exceedingly slow as measured by land standards.

Even in the Navy after the Trenton's installation, although a few early lighting installations were effected and several miscellaneous experimental power installations on auxiliaries, no distinct progress was made until 1898 to 1900, when the Battleships *Kearsage and Kentucky* were constructed with electric plants of seven 50-kw. engine-driven generators and with the major portion of the auxiliaries electrically operated. Since 1900 the use of electricity in the Navy has progressed very rapidly until, as we have stated, at the present time nearly all power applications are electrical, including electrical propulsion for capital ships.

In the merchant marine field comparatively little progress was made in this country in the use of electricity after the first installation on the *Columbia*, until about the beginning of the World War in 1914, although we appreciate that small electric lighting plants had come into general use, and in a few instances electricity had been used for power applications on merchant vessels.

In 1914 the writer presented a paper before the A. I. E. E. on "Electricity the Future Power for Steering Vessels," in which he predicted from the experience then had in the Navy, that electricity would be, in the future, generally used as the power for the steering of vessels.

In a paper presented before the Naval Architects' and Marine Engineers' Society in 1917, outlining the progress which had been made in the use of electricity in the merchant marine, we expressed the belief that the time was rapidly approaching, if not already here, when the results as then obtained would justify the construction generally of vessels electrically equipped in all or many of their power applications.

Growth and Adoption

The advent of the fuel oil engine-driven ship has marked a great stepping stone in the adoption of electric power, particularly for auxiliary purposes. The first notable instance of this kind was the vessel *Christian X* constructed by the Burmeister and Wain Co. of Copenhagen, and its first voyage to this country in about 1913 or 1914 created marked attention. Since that time it is understood that 70 or more vessels of this type have been constructed or projected by that company.

In 1916 and 1917 a number of merchant vessels was built in this country including tankers and cargo vessels employing electrical auxiliaries, among others being the tanker *La Brea* with electrically operated pumps, and the tanker *Solitaire* completed last year by the Texas Co. having oil engine drive and electrical auxiliaries throughout, including electric heating. Other instances were a number of tank vessels constructed by the Pennsylvania Shipbuilding Co., propelled by geared steam turbines and having electrical auxiliaries operated by a-c. motors. At the present time there are quite a number of oil engine-driven cargo vessels with electrical auxiliaries, and others with electric drive and electrical auxiliaries, being constructed and projected in this country, and in the opinion of certain editorial writers, the outlook was never more favorable in this country, particularly for construction of oil engine-driven vessels, than at the present time. Motorships are now under construction for the American-Hawaiian S. S. Co., the U. S. Shipping Board, the Standard Oil Co., the Alaskan S. S. Co. and the Submarine Boat Corporation, and quite a number more are under contemplation for this year.

Rapid strides are being made by European countries in the adoption of the use of electricity on their merchant vessels, particularly of the motorship type, and England, as well as Scandinavian countries, is now constructing many vessels of this type. One of the most recent examples was the maiden voyage of the motorship *La Paz* to New York which was constructed by Harland and Wolf of Glasgow, which company is also constructing five additional motorships for the same line. A visit to the *La Paz* showed numerous interesting features in connection with her electrical equipments.

Generating Plant and Systems of Distribution

In the selection of the generating plant for the electrically operated vessel, considerable thought is necessary as to the number and size of the units to be installed. A number for instance, of the Burmeister and Wain vessels have three 60-kw. machines, 230-volt; the English vessel *La Paz* has three 100-kw., 230-volt; the tanker *Solitaire* has three 45-kw. and one 10-kw., 230-volt; the *Cubore* is provided with three 100-kw., 250-volt sets. The aim is in general to provide an equipment which is sufficiently flexible to permit of

Presented at the Joint Meeting of the N. Y. Section of the American Institute of Electrical Engineers and the Metropolitan Section of the American Society of Mechanical Engineers, New York, N. Y., January 28, 1921.

the operating of all auxiliaries and lights with one machine when cruising and to operate the vessels while handling cargo in port with two machines, or under possibly extreme emergency conditions three machines, one machine being however in practically all cases considered as a spare. Much division of opinion exists however, as to the wisdom of going to as many as three units, some claiming a preference for two units of larger size.

These installations have in general been two-wire d-c. systems, and such vessels as the *La Paz* and *Solitaire* have been furnished with lights at 230 volts. Generally satisfactory results are reported from the *Solitaire* for lamps of this high voltage with the exception of the small instrument lamps which are frequently broken. The officers of the *La Paz* reported frequent breakage and rather unsatisfactory results. A practise which has

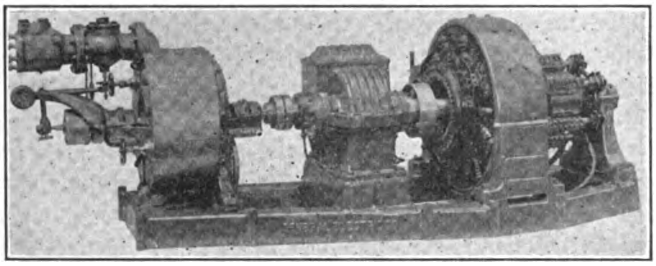

Fig. 1—Small Steam Turbine Geared to D-C. Generator, 100-Kw. Capacity, Suitable For Furnishing Power for Electric Auxiliaries on a Steamship

been followed by the Burmeister and Wain Co. and has found general favor amongst engineers in this country also, is the use of a small motor-generator set for reducing the 230 volts of the generators to 110 or 115 volts for the lamps, and providing this small machine with sufficient flywheel effect also to smooth out any pulsations from the auxiliary oil engines and fluctuation of voltage due to sudden changes of loads on the generators. The 110-volt lamps are furthermore in addition to being mechanically stronger, more universally obtainable.

Direct Current versus Alternating. A few years ago a considerable controversy existed between engineers as to the advisability of the use of alternating and direct current on shipboard, and as previously outlined in 1916 to 1917 a number of vessels was constructed in this country, including vessels of the cargo and tanker type, which had a-c. equipment. It was contended by some at that time that direct current was impracticable, particularly for tanker vessels, owing to the danger of igniting inflammable gases by sparks moving from contacts, etc. We believe, however, that later developments have quite clearly disposed of these contentions and shown the wisdom of providing in general, for auxiliary equipments on shipboard, the d-c. system; and we understand that some of the vessels which were constructed in 1916 and 1917 with the a-c. outfits have not proved themselves nearly as satisfactory as d-c. installations. The direct current has a distinct and decided advantage in the flexibility and extent of speed control obtainable, and in the obtaining of speed and torque characteristics for hoisting apparatus such as deck winches, windlass and capstan, which cannot be furnished by the a-c. motor. There is no advantage furthermore, on a vessel from the distribution standpoint, in the use of alternating transmission, and a 3 or 4-wire system is more expensive and complicated than the straight 2-wire d-c. distribution. We note that English authorities have recently appeared definitely in print to the above effect, recommending strongly also against the use of a voltage higher than 220 generally throughout the vessel.

With regard to tank vessels, it is possible to furnish motors entirely enclosed, gas and watertight, and where location renders the same desirable, to furnish forced ventilation through the enclosed motor cases. The experience of the tanker *Solitaire*, which was thus equipped, has been to date very satisfactory and two tankers, the *Watson* and *Hillman*, are being constructed with d-c. equipments on the Pacific Coast for the Standard Oil Co.

Marine Types of Electrical Apparatus

Various types of electrical apparatus, generators, motors and controllers are required for the electrical auxiliaries on board ship, according to their location, duty and general requirements, which are discussed in some detail below.

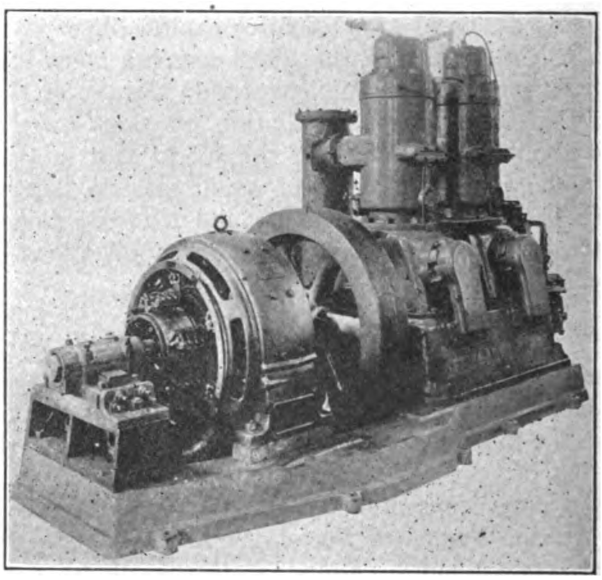

Fig. 2—Oil Engine-Driven Generator Set, 60-Kw. Capacity Suitable for Furnishing Power for Electric Auxiliaries on Motorships

Generating Plant. For steam-driven vessels, steam-operated generating sets are naturally employed, of the reciprocating engine type for small plant equipments in some cases, but turbo generating sets are now almost universally employed for this purpose. These are usually also of the geared turbine type, all parts mounted on a common bedplate as illustrated in Fig. 1, which set is of 100-kw. capacity.

For motorships, oil engine sets are naturally employed with generator mounted on a common bedplate and the flywheel of suitable proportions to assist the regulation and smooth out the voltage fluctuations. A 60-kw. generating set of this type is illustrated in Fig. 2.

As previously explained, on vessels utilizing appreciable amount of electrical power these sets are provided usually two or three in number in accordance

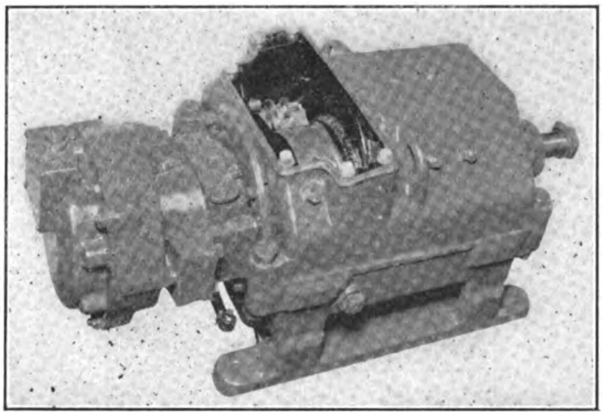

Fig. 3—D-C. Watertight Type of Motor With Disk Brakes for Deck Auxiliaries—Motor Provided With Self Oil Ring Bearings

with the general requirements of the complete installation and the particular ideas of the designing engineers. These sets are now in all cases furnished with open type generators, but in many instances are protected by hoods or metal shields from drippings due to moisture condensation and throwing of oil.

Motors. For driving the various auxiliaries, motors of the open, ventilated or enclosed watertight type

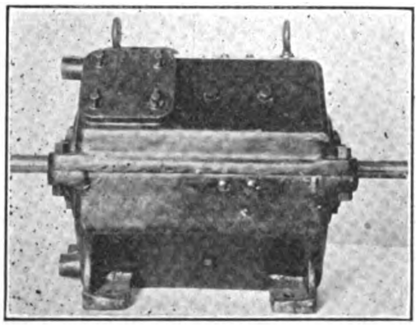

Fig. 4—D-C. Watertight Type of Motor Arranged for Disk Brake (not Shown) Suitable for Deck Auxiliaries —This Motor is Provided With Ball Bearings

are employed, especially the two latter types as but few installations justify the use of entirely open motors.

For deck auxiliaries such as windlass and deck winches, entirely enclosed watertight motors are essential, which must be made strong and sufficiently watertight to withstand such submergence as is occasioned by heavy seas coming over the vessels. This condition therefore, practically necessitates the use of stuffing boxes or similar means around the motor shaft to exclude water, and particular attention must be paid to the design of bearings to insure proper lubrication and operation under roll of the ship. Figs. 3 and 4 illustrate motors of this type, Fig. 3 showing a motor with watertight disk brake mounted and provided with oil ring bearings. Fig. 4 illustrates a watertight

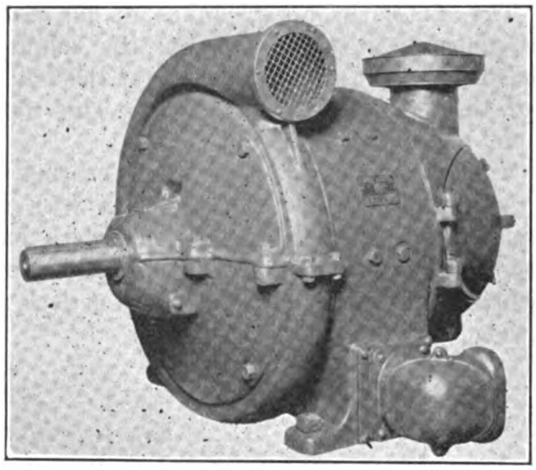

Fig. 5—Enclosed Ventilated Motor Suitable for Engine Room Auxiliaries, Steering Gear, etc.

The involute may be assembled right or left hand and arranged for any angle of discharge. The cowl of the intake may be omitted and top opening closed and air taken in through opening at bottom.

motor with provision for disk brake, not shown, and provided with ball bearings, which are coming into considerable favor for shipboard use to meet the above conditions.

For operation of engine room auxiliaries, such as

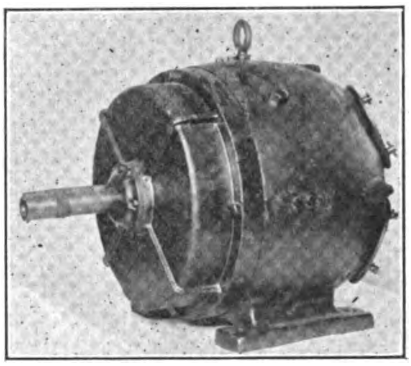

Fig. 6—Enclosed Ventilated Ball Bearing Type Motor Suitable for Driving Engine Room Auxiliaries, Steering Gears, etc.

Air is taken in through mesh in one of the lower front covers and discharged at bottom of casing in rear.

pumps, compressors, etc., open or entirely enclosed watertight motors are occasionally employed but the ventilated type of motor finds particular favor for this purpose as it provides protection against drippings and at the same time permits the use of smaller motor frames for the same duty than when absolutely watertight. Figs. 5 and 6 illustrate motors of the ventilated construction which are provided with internal fans driven from the motor shafts. The involute of the

motor shown in Fig. 5 may operate either right or left hand, depending upon the rotation of the motor, and may be rotated so as to discharge downward and prevent water from entering from above. The cover on the intake may also be omitted, the top opening closed, and air taken through the screen opening at the bottom if desired. This motor is of the oil-ring type. The motor in Fig. 6 takes its air normally through opening at the bottom of the commutator end and discharges through opening at the bottom in the rear through the motor housing. This motor is of the ball bearing construction.

Fig. 7 illustrates a watertight ball bearing motor which is suitable for use in connection with engine room auxiliaries, cargo pumps, etc. where entirely enclosed motor is desired, although the same would not be of suitable design and construction for deck auxiliaries owing to type of frame.

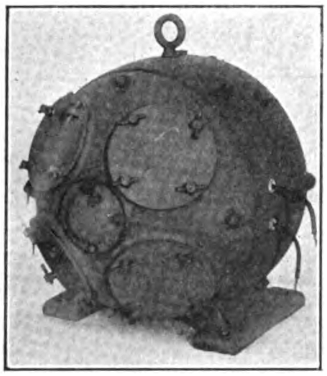

Fig. 7—Enclosed Watertight Ball Bearing Type Motor Suitable for Operating Certain Engine Room Auxiliaries

For steering gears any one of the three types mentioned might be employed, although the steering gear motor is usually in sufficiently protected position to permit of open motor or one at least of ventilated construction.

Controllers. As in the case of motors, several types of controllers are utilized, according to the installation conditions and duty to be performed. These consist of the panel, drum or contactor type, either open. enclosed non-watertight, or watertight.

For the operation of certain of the auxiliaries where watertight constuction is not considered necessary but where it is desired to prevent unauthorized manipulation and render the controller drip-proof, a manually operated panel with hinged doors provided with lock and key is employed, as illustrated in Fig. 8, which shows a manually operated starter and speed regulator, especially suitable for the control of small motors.

Where watertight or gastight protection is desired, a manually operated watertight panel type controller such as illustrated in Fig. 9 is frequently utilized. This shows a motor starter and speed regulator operated by control levers extending through stuffing boxes in the front cover. Gum rubber gaskets with clamping devices are furnished to insure watertightness.

Particularly where installations are in somewhat inaccessible positions, automatic controllers operated by push buttons now find great favor, as the buttons can be located in a very convenient location, and furthermore, the operation of starting the motor is automatic and taken out of the hands of the operator. Such controller is illustrated in Fig. 10 which shows an automatic starting box push-button operated, with gastight enclosing case which is furnished watertight if desired.

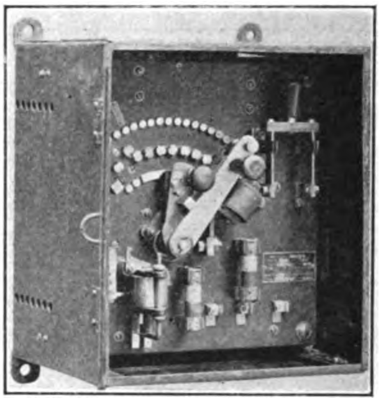

Fig. 8—Enclosed Splash-Proof Hand Starter and Speed Regulator Suitable for Operating Certain Small Engine Room Auxiliaries

For deck machinery, such as winches, windlass, capstan, etc., a manually operated watertight drum is frequently employed which, owing to its watertight construction, can be mounted at the auxiliary above decks. Such a controller is illustrated in Fig. 11.

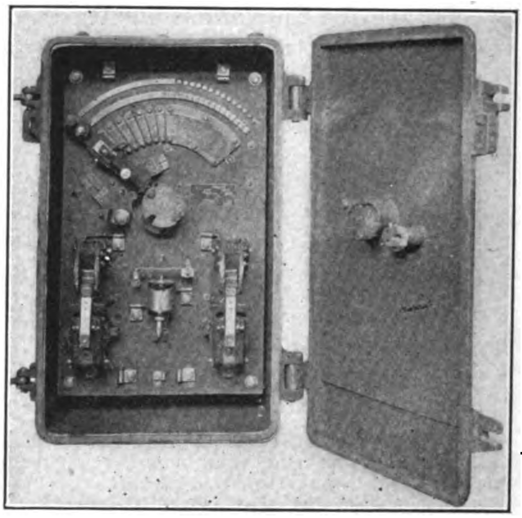

Fig. 9—Enclosed Watertight Hand-Operated Starter and Speed Regulator Suitable for Certain Engine Room Auxiliaries and in Some Cases Deck Auxiliaries

Centralized Control. A method of control of the auxiliaries, particularly on tank vessels, which has found favor in some quarters, mounts the control

apparatus, except for the deck winches and windlass, all on a centralized control board in the main engine room. In the case of tankers this takes the controlling apparatus away from cargo pumps etc. where there is danger from explosive gases. With this arrangement automatic starting controllers are provided for each auxiliary at the board, and there is a push-button station at the auxiliary itself, for signaling to the engineer to start the apparatus, and for stopping the apparatus at the auxiliary if desired. When the signal is received the operator at the switchboard closes the line switches or circuit breakers and the equipment is automatically started. Such an arrangement is illustrated in Fig.12 as installed on the tanker *Solitaire*, and reports from officials of the Texas Co. indicate entire satisfaction with the arrangement.

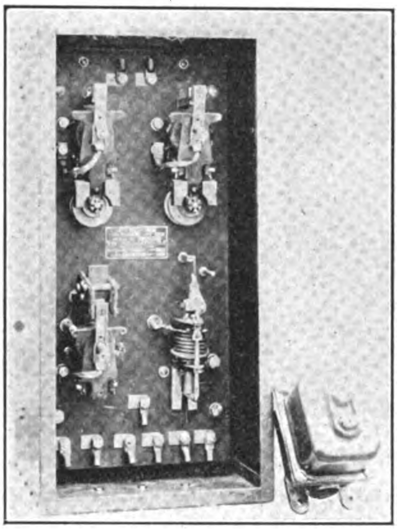

Fig. 10—Enclosed Gastight and Watertight Push-Button Automatic Starter Suitable for Engine Room Auxiliaries

Ship Auxiliary Requirements

The name auxiliaries has come to apply to practically all power-driven pieces of apparatus on board ship outside of the main propelling machinery. The auxiliaries, while differing somewhat for steam and oil engine-driven vessels, have many features in common, the principal difference being that in the case of the oil engine-driven vessels, certain of the pumps, including feed water, condenser water, etc., are replaced by oil pumps, air compressors, etc. While there appears at the present time, to be little if any argument regarding the use of electric auxiliaries on oil engine-driven vessels, the question seems to be still considerably under debate as to their use with steam-propelled vessels, which point we will discuss later.

In all shipboard work reliability is of the first importance and electrical apparatus for ship auxiliaries must be substantially constructed, yet at the same time need not be clumsy as we are frequently led to feel is the case with many of the European designs. Furthermore, each piece of electrical apparatus should be particularly designed for the service and conditions to be met. These conditions need to be carefully *studied* and too great emphasis cannot be laid on this

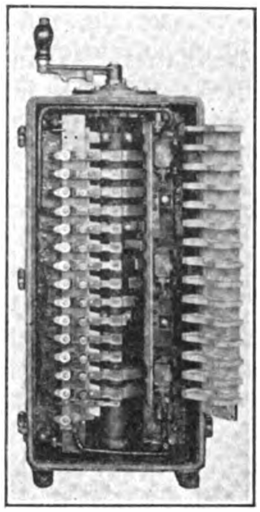

Fig. 11—Watertight Hand-Operated Drum Controller Suitable for Operating Exposed Deck Auxiliaries or Engine Room Auxiliaries in Certain Cases

point, as it is at the root of the successful operation of electrical machinery. Motors on deck will in many cases frequently be awash and hit by heavy seas, also, when the crew is washing down the deck the hose

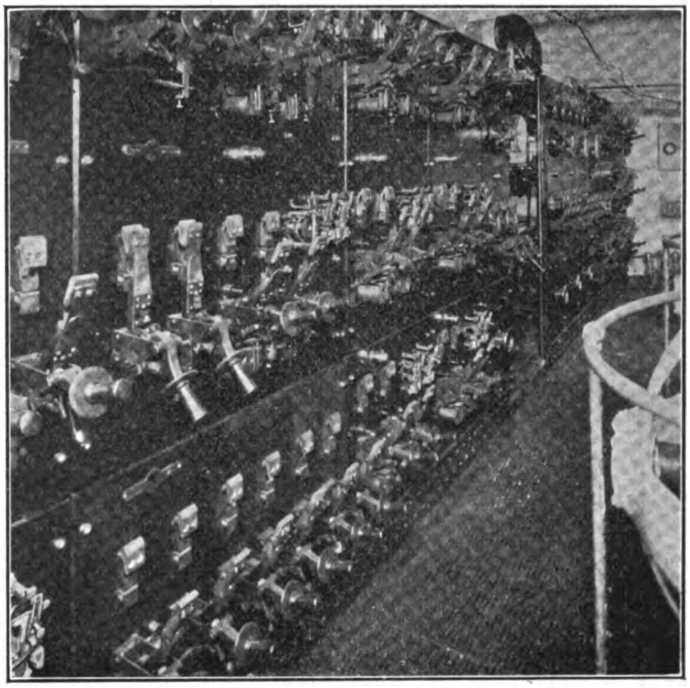

Fig. 12—Switchboard for Engine Room Auxiliaries on Motorship *Solitaire*

will often play over the motors. Vessels trading in tropical climates will have deck machinery subject to the excessive heat of the tropical sun, and all vessels on northern routes have their deck motors at times

subjected to very low temperatures. In the engine room leaky steam pipes are a danger to the motors, and where Diesel engines are employed for the propelling machinery, thought should be given to the protection of motors and controllers from oil fumes and drippings.

Engine Room Auxiliaries. As an example of the engine room auxiliaries which are included in a large oil engine-driven vessel, we give below a list of those supplied on one of our latest motorships, the *Cubore*, of 11,500 tons d. w. c.

Auxiliary	No	H.P.	Location	Motors Type	Motors Open or en.	Control Type	Control Open or en.
Fresh Water Pump	1	5	Floor	Hor.	Encl. Vent	Mag.	Encl.

Generator	2	100 k.w.	Floor	Oil engine-driven			
Generator (Emergency Set)	1	100 kw.	"	Geared steam turbine-driven			

For a steam-driven vessel many of the above auxiliaries will be similarly used in the engine room with the replacement of the several oil pumps and engine circulating water pumps by boiler feed, condenser, condensate pumps, etc. In connection with the pump equipments either piston reciprocating or centrifugal pumps are generally used with water or steam service systems, the centrifugal pump being especially favored for engine circulating, condenser, and sanitary service, the selection however, usually depending upon the opinion of the designing engineers. Some form of rotary type pump is usually employed for oil service systems. For reciprocating and rotary pumps the constant-speed shunt-wound motor is best adapted, but for the centrifugal a wise provision includes a small percentage of series winding to prevent excess speed and loading of the motor. Field control of a wide range is frequently provided for many of these pump equipments, in some instances to vary the pump delivery, but in the case of the centrifugal pump a small amount of field control is sometimes added to advantage to assist adjustment of the load and speed.

The air compressor and engine turning motors can be provided with an appreciable amount of compound winding to advantage, and machine tool motors such as lathe, drill, etc. would usually require shunt-wound variable-speed motors.

The control for these engine room auxiliaries would be generally by the hand-operated watertight panel or the push-button watertight construction as illustrated in Figs. 9 and 10 unless the centralized control previously described were utilized.

Deck Machinery. The deck machinery equipments, consisting of windlass, deck winches, capstan and steering gear, may be considered separately to advantage.

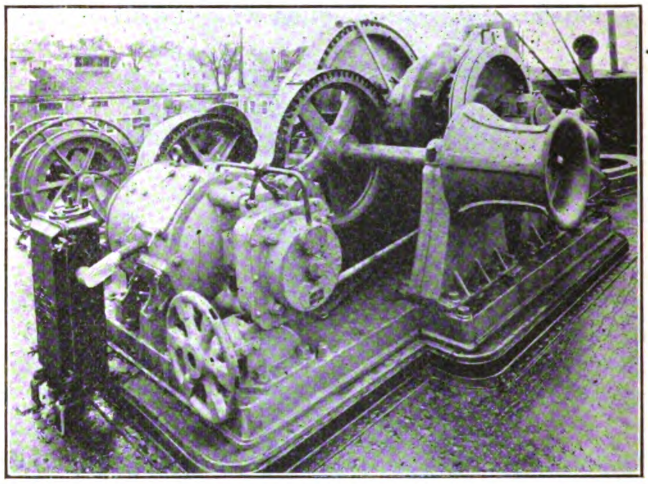

Fig. 13—Windlass Equipment Installed on Motorship *Solitaire*

Watertight oil ring bearing motor with disk brake and watertight drum controller.

Windlass. For the windlass equipment a watertight motor is essential, and a manually operated drum controller, if installed on and operated from the deck. Frequently however, control equipments are provided non-watertight and installed below deck with shaft extensions through stuffing box, or a contactor equipment remotely controlled with small watertight master on the deck and non-watertight automatic panel below deck. A compound-wound motor can be used to the best advantage usually for the anchor windlass, particularly when of the spur-geared type, and provisions must be made in the control for stalling the motor on any controller point in case of fouling the anchor on the bottom or jamming of the gear. Fig. 13 illustrates a windlass equipment as installed on the tanker *Solitaire* with manually operated watertight drum.

Deck Winch. The auxiliary upon which probably more thought and study is being given at the present time from an electrical standpoint, than any other on shipboard, is the cargo deck winch. This is an especially important piece of machinery on a vessel handling miscellaneous cargo; and reliability of operation, and range of speed control in both hoisting and lowering, are of prime consideration. Deck winch motors should

be of the general construction as shown in Figs. 3 and 4, and the control, if manual, would be similar to the watertight drum shown in Fig. 11. An illustration of a deck winch which has been particularly designed for the service, is shown in Fig. 14. With this arrangement drum controller and resistances are all mounted within the winch base, the rheostats being ventilated through adjustable openings in the sides. Fig. 15 shows an electric winch as installed on the *Solitaire,* with manually operated watertight drum and separate

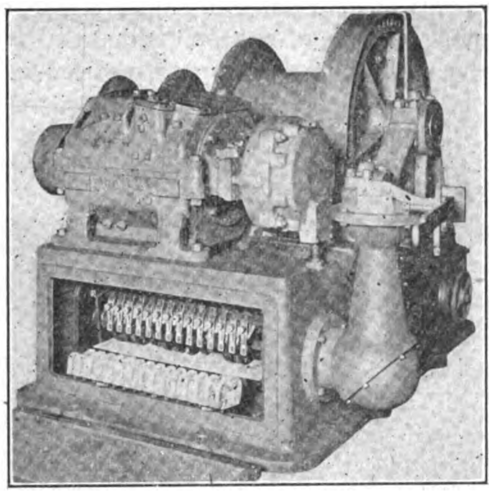

Fig. 14—Self-Contained Deck Winch with Exposed Watertight Motor and Disk Brake—Drum Controller and Rheostat Mounted in Base

rheostat box arranged especially for ventilation, when in operation, by means of a hand wheel.

Much discussion has been had of late with regard to the exact type of control to be furnished for deck winches and the results to be accomplished. One manufacturer is strongly advocating at the present time, the electrically operated winch, provided, however, with mechanical load lowering brake in place of the customary dynamic electric lowering control. While differences of opinion naturally exist on these details, one point is obvious: That the ideal electric winch is one which provides as nearly as practicable, a straight horse power curve, accommodating its speed automatically to the value of the load and permitting the handling of light and heavy loads without the necessity of changing gears; also that it gives in lowering as nearly as practicable, corresponding range of speeds for heavy and light loads down to the empty hook. And it must be borne in mind that time gained in the hoisting and lowering of the empty hook is that much clear gain in loading and unloading the vessel.

In the case of deck winch equipments and anchor windlass as well, it is the practise to provide a mechanical brake on the motor shaft, electrically operated, to prevent falling of the load in case of failure of voltage.

An arrangement of control for the deck winches which has been used to some extent and was recently illustrated in the cases of the motorship *La Paz,* provides a small deck housing between or adjacent to the hatches and in the center of a group of winches. In this small deck housing is placed the main controlling apparatus of the contactor type, as well as the rheostats all of open construction. At the winch itself is provided a small watertight master controller carrying contacts only for the operation of the contactors within the deck housing. This arrangement we believe is worthy of serious consideration as it groups the apparatus together to advantage, makes the apparatus readily accessible, and permits of good ventilation to the rheostats, thus permitting less capcity and smaller resistances.

Capstans. Capstan equipments, where used, are frequently so arranged as to permit installation of the driving motor in a compartment below decks, thus allowing an open or at least a self-ventilated motor, which is usually furnished heavily compound-wound to provide the varying torque characteristics necessary with this equipment. The control, in its simplest form, may be a plain starting hand-operated or push-button controller, but the best practise provides stalling features and dynamic or armature shunt control on one or more points in either direction for use in paying out cable. The motors should be usually provided with an electrically operated mechanical brake as the drive is often through gearing efficient enough to permit overhauling.

Steering Gear. The early stages of development of the electric drive as applied to steering gears, is quite generally covered by the writer's paper before the

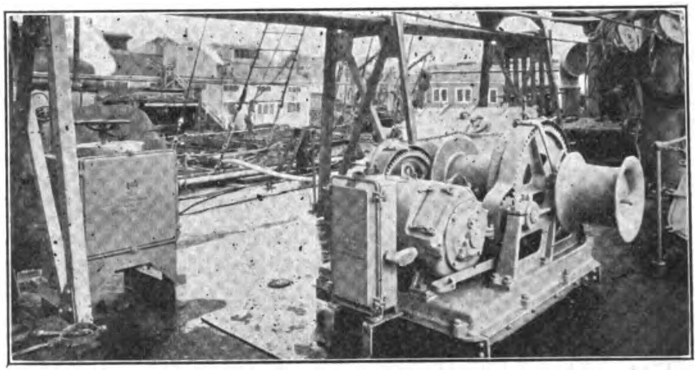

Fig. 15—Deck Winch Equipment Installed on Motorship *Solitaire*

Watertight ball bearing motor with watertight drum controller and watertight rheostat box (shown at left) ventilated by means of hand wheel.

A. I. E. E. in May 1914, which describes in detail the direct application of electric drive where a motor is geared directly to the transmission, frequently of the screw gear type, as illustrated in Fig. 16. With this arrangement the motor is operated by a contactor panel remotely controlled from the bridge, usually on the non-follow-up system, although electrical follow-up control has been designed and some times employed.

This direct electric application is simple in design

and effective and reliable in operation, as clearly demonstrated by extended experience which the Navy has had, and has led furthermore by its simple and reliable arrangement of control, to the abandonment entirely of the use of the follow-up gear. Opinions among seafaring men are very much divided still however, as to the wisdom of the use of the non-follow-up gear in merchant marine, although it is being tried in a number of cases with perfect success.

This direct method of drive, however, is accompanied usually by a very inefficient mechanical transmission, the screw gear for instance giving an efficiency usually of 30 to 40 per cent. As a means therefore, of providing more efficient transmission, the hydraulic speed gear is now frequently employed particularly for installations of large horse power where the saving, owing to the more efficient transmission, is very marked. With this arrangement the constant-speed motor operates the hydraulic pumps which supply oil to hydraulic rams operating the rudder cross-head, this hydraulic transmission therefore, entirely replacing the ordinary screw or other type of mechanical gear. Such an arrangement is shown in the Fig. 17 which covers the hydroelectric steering gears as constructed for the scout cruisers Nos. 4 to 13. This navy equipment has duplicate driving motors of 60 h. p. each and duplicate pilot motors for operation of the valve mechanism of 1½ h. p. each. The control for the main and pilot motors is by the contactor panels shown in the foreground, and the control from the bridge is furnished by operation of the small pilot motors through the control panel on the non-follow-up system.

For merchant vessel work, open or ventilated motors are usually employed. If for the direct-connected electrical type they would be compound-wound, and for the hydraulic system shunt-wound. For the control of the direct-connected type, contactor panel would be supplied in the steering gear room with steering stations at such points as desired, with a selective switch on the control panel to delegate the control to any one of these. For the hydraulic system the control equipment resolves itself usually to simply a starting panel for the main motor and in merchant work the control of the valve with the hydraulic gear has been frequently by means of a hydraulic telemotor or tiller rope transmission. Electric pilot motor control, however, can and has been supplied in either of the follow-up or non-follow-up type.

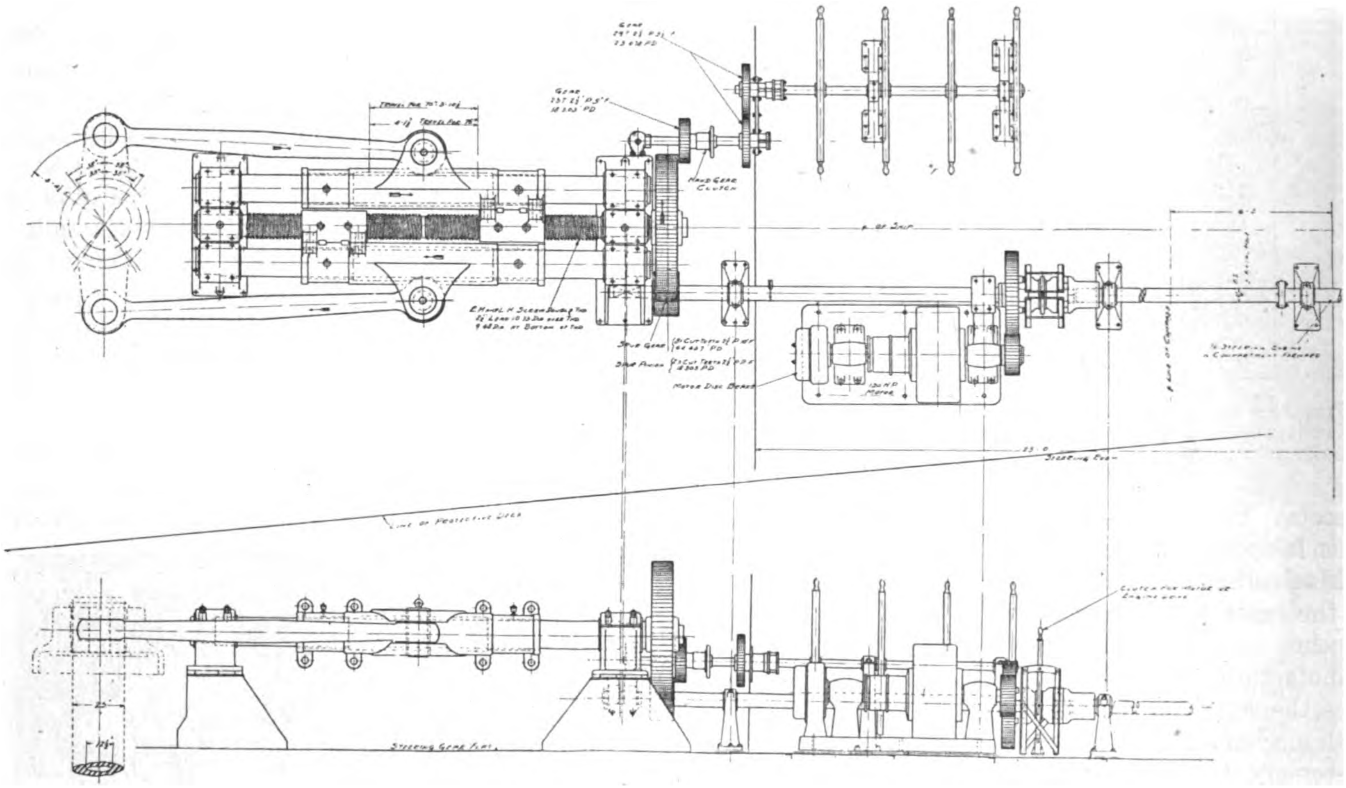

Fig. 16—Direct Application of Electric Drive to Steering Gear of the Screw Type With Open Type Motor (This Equipment as Installed in the Navy Provided With Both Electric and Steam Drive).

Advantages of the Electric Drive

It has been shown by experience, that the electric drive of the auxiliary machinery has resulted in a considerable saving in fuel consumption of a vessel. Also, the more efficient the propelling machinery, the greater the saving that may be otained by the adoption of electric auxiliaries. This is due to the fact that with steam-driven auxiliaries, the exhaust steam from the auxiliaries in the engine room is utilized principally for feed water heating. Where the total steam consumption, including propelling machinery, is

heavy, a larger quantity of this exhaust steam can be efficiently utilized than where the total steam consumption is not as great. This applies only to such auxiliaries as are in constant use during the voyage. It is evident therefore, that until the limit of feed water heating has been reached, the reduction in the steam consumption taken by the auxiliaries will not have nearly as great effect on the fuel consumption, as would be the case after this critical point has been passed. The limit of feed water heating is more quickly reached of course in the case of the most efficient propelling machinery. Ideal conditions would be obtained when the exhaust steam from the turbo generator for instance, is just sufficient to obtain the limit of feed water heating during the voyage. With turbine drives the surplus of exhaust steam is sometimes turned

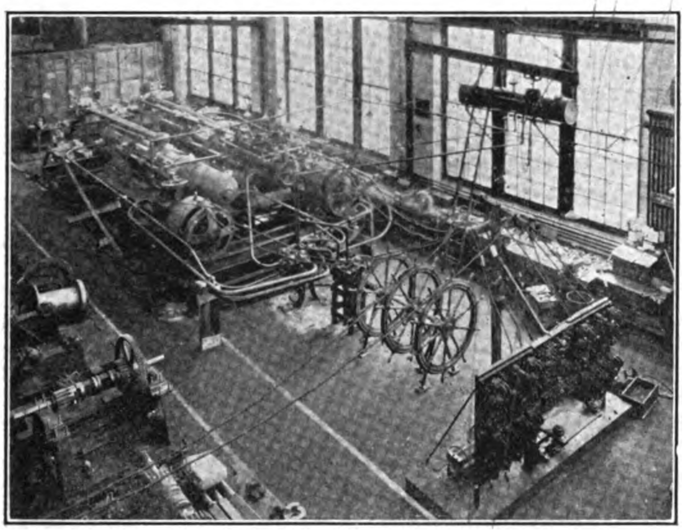

FIG. 17—HYDROELECTRIC STEERING GEAR (IN MANUFACTURERS' SHOP) FOR NAVY SCOUT CRUISERS NOS. 4 TO 13

Two 60-h. p. main driving motors and two 1.5-h. p. pilot valve motors are provided, one main and one pilot motor being furnished as a standby. Control panel shown in foreground.

into the low stage of the turbines, but how efficient use can be made of more auxiliary exhaust steam, than above outlined, as necessary for feed water heating and some times other minor purposes, is not apparent.

The above applies particularly to vessels using steam for their main propulsion. For ships operated by Diesel engines or Diesel electric drive, it is obviously of great advantage to operate all the engine room auxiliaries by electricity as it is largely a question of the efficiency of electric transmission with a large and reliable generating unit, against a number of small inefficient oil or steam engines, and it is naturally desired to avoid the generation of steam in any quantity on a motorship.

Aside from the engine room auxiliaries referred to above, attention is particularly drawn to the deck auxiliaries which are located some distance from the generating plant and where great losses would take place in the steam pipes feeding them. In these cases the electric drive is by far the most efficient method, irrespective of whether the vessel is steam or oil engine-propelled. It has always been noted by the writer that there is an almost complete absence of reliable figures on steam consumptions of steam-driven auxiliaries and inquiries usually bring out simply the information that an 8 by 10 engine for instance, etc., is used, without any data as to its actual efficiency or steam consumption. Some idea can be obtained of the loss of steam on the steam type of auxiliary when it is remembered that it is frequently considered essential to keep steam on the winch and windlass engines in cold weather to prevent the cylinders cracking or pipes bursting from freezing. The steam steering engine is a particularly noteworthy example of the wasteful use of steam as it is in effect only a steam ram taking steam full stroke with valves always left cracked a small amount.

The electric motor is always operating at a point of high efficiency and does not suffer in this respect from change of climatic conditions. Furthermore, the power transmitted through electric cables is practically a constant quantity regardless of temperature conditions, while steam transmission is affected very decidedly thereby.

The electric drive in addition to its convenience, adaptability and ease of operation, has the further merits of being available at any instant without preliminary warming up, or as above stated, the losses while standing idle with the steam plant.

Space, Weight and First Cost. Comparative figures which have been reliably obtained indicate generally some increase in the weight and space occupied for the electric over steam drive. In some cases however, such as the steering gear, an actual saving in space and weight is usually effected with the electric, and in other cases the difference is very slight. In the matter of first cost, it is also apparent from such figures as have been available to date, that electrical auxiliary machinery is roughly about 20 per cent more expensive than steam, except in case of deck winches where the difference is more, sometimes 100 per cent. It is also found that an oil engine-propelled motorship is about 30 per cent more expensive in first cost than a steam-driven vessel and that strange as it may seem, the Diesel electrically propelled ship is slightly less expensive than the straight Diesel owing to the smaller and higher speed oil engines which it is possible to utilize. These figures of first cost however, we feel are influenced to a considerable extent at the present time by the lack of a developed line of apparatus on the part of many manufacturers and that in many instances full development costs have been charged against the first installations of electric auxiliaries which would be absorbed in later installations.

As against these disadvantages of first cost and weight, are obtained the advantages of:

1. Suppression of heat in spaces adjacent to the

gear and transmitting lines, which is of importance in certain cases.

2. Elimination of accidents due to freezing and bursting of steam pipes, cylinders, etc.

3. The reduction of vibration and noise and an increase in the habitability of the ships due to these factors. This is particularly marked in the case of the steering gear.

4. The simplification and flexibility of control, operation being obtained readily from the most convenient point.

5. The obtaining of mechanisms as outlined above which are very much more efficient in operation than the steam equipments. This is the most important consideration.

Economy of Operation. That without question a very appreciable saving in the fuel consumption can be obtained by the use of electric drive, there is little doubt, and L. Miller, an English writer, has recently stated that in the modern equipment with propelling machinery consisting of double reduction geared turbines using superheated steam, a saving of 8 to 10 per cent of the fuel bill can undoubtedly be obtained by the adoption of electric drive on the auxiliary machinery. He further states that tests recently made on a modern equipment, as far as the propelling machinery was concerned, and where steam-driven auxiliaries had been adopted, the steam consumption in the main turbine was 10 lb. per shaft horse power, and the steam consumption of the auxiliaries running during the voyage was found to be 30 per cent of the total steam consumption of the whole vessel. This figure is further borne out by observance and tests in this country and shows what an important part of the total load of the vessel is made up of the auxiliaries in the case of the steam equipment, and the opportunity for economy in this department.

Another important consideration is the fact that experience shows on motorships already constructed with electrical auxiliaries, that in port the power required during the period that the deck winches are handling the cargo is about three times the amount required with the auxiliaries at sea. Investigation of cargo handling vessels in general has shown furthermore that winches are idle five to eight times the amount of time they are in operation during an eight hour day of work. With electric drive, power is completely shut off while the winches are out of operation, but in the case of the steam equipments condensation and leakage continues the same.

While we have numerous general advices to the effect that the fuel consumption of steam-driven auxiliaries is at least ten times that of electric, etc., we have some specific figures from oil engine-driven vessels of the *Benowa* and class which are in operation on the Chilberg line and plying between Australian points and the Pacific Coast. The following figures are given for two vessels, the *Benowa* equipped with electrical auxiliaries, and the *Cethana*, equipped with steam auxiliaries:

	Benowa	*Cethana*
Net registered tonnage........	1788	1800
Propulsion....................	2–500 h. p. Diesel eng.	2–500 h. p. Diesel eng.
Average daily fuel consumption main engines...............	1350 gal.	1365 gal.
Average daily fuel consumption-donkey boiler..............		557 gal.
Average daily fuel consumption-auxiliary engines............	42.5 gal.	
Total daily fuel consumption...	1392.5 gal.	1922 gal.
Per cent of total fuel used for auxiliaries..................	3.4%	29%

The above shows a saving of approximately 25 per cent in fuel consumption due to electric auxiliaries. Examination of the records of other ships shows a similar percentage gain.

The above figures were obtained from the logs of these vessels and are corroborated furthermore, by communications from the officials of the Line. We, moreover, would understand that for two of the vessels of this class for a period of four days in port handling cargo eight hours a day, that the total fuel consumption of all auxiliaries in operation was 5.3 times more for the steam-operated than the electric. In handling miscellaneous general cargo during this period also, approximately 20 per cent more cargo was estimated as handled with electric winches than with steam. The steam-equipped vessel was supplied with two donkey boilers and eight 7 by 10 steam winches.

We have incidentally, in addition, advices that for two sister ships recently constructed and operating in the Pacific, one equipped electrically and the other with steam auxiliaries, for a period of six months the repair bill on boilers and steam winches was $3800.00, while repairs on the generating sets and electric equipment for the same period amounted to only $92.00. We appreciate the fact of course that this was undoubtedly an unusual condition, some accident probably happening to the steam plant, but we emphasize the point that repairs are necessary to steam equipments and that if some repairs are occasionally necessary for the electric, it should not be considered a matter of discredit to the electric drive.

Correct Atmosphere of Thought

In the consideration of the use and adoption of electricity for ship auxiliaries, it has been necessary to develop a new line of thought in the minds of steamship owners, naval architects, marine engineers, etc., and while we believe that still more must be accomplished in this respect, considerable progress has been made.

This progress is noteworthy, especially in view of the opposition which had been encountered to the use

of electricity until recently, from many of the above interests and manufacturers of steam apparatus in general. In some instances in the past these interests have freely stated that they would use their best efforts to defeat the use and adoption of electric auxiliaries on merchant vessels.

We have made but little reference to the wide application of electricity in the American Navy and the very satisfactory results which have been obtained from practically all of its apparatus so operated. This at least in a general way, is known by the majority of the members of these two societies, and further, has, we believe, had a very important bearing on gradually changing the mental attitude with reference to the merchant field. It is frequently remarked however, that results can not be obtained on merchant ships similar to the navy, owing to the much higher class of operators on the navy vessels and the fact that the average freight vessel does not carry men in any way familiar with electrical apparatus. You frequently used to hear also remarks made in connection with a contemplated vessel or one under construction, that the general use of electricity would require a generating plant of possibly 100 or 200-kw. sets, whereas the generators which they had, or had contemplated purchasing, were in the neighborhood of 10 to 15 kw.

It is obviously essential that a ship using electricity to any extent should have a power plant of equivalent size, and equally important that such vessels should be provided with at least one operating engineer who is sufficiently versed in electrical matters to be able to make slight adjustments and repairs in the same way that steam engineers can repair steam machinery and consider the same really as a part of their regular duties.

Owing to the general unfamiliarity of the operators in the past with electrical equipment, it has frequently occurred that criticisms were made of the performance of the electrical apparatus, although defects or casualties were of a minor nature, whereas a similar casualty to a steam device would be taken entirely as a matter of course. As an instance of this mental attitude, we have been reliably informed that in the case of one of the motor ships recently put into operation in this country, several trouble reports had been received outlining in some detail minor defects experienced with the electrical apparatus; but in the case of the Brown telemotor for steering gear where trouble was experienced for about five hours on one occasion, the incident was taken entirely as a matter of course by the officers of the vessel and no report whatever was submitted, it being later only noted from the ship's log. It is therefore, particularly desirable to educate, in a general way, the officers of the vessels in the merchant service to the use of electricity, and although they may not have in any sense the experience or training of electrical engineers, once they become familiar with its general use, the major part of the present criticisms will have disappeared.

Some failures of electrical equipments have been naturally encountered and reports of these matters have been naturally stressed considerably, as bad news always travels faster than good, but in the majority of cases when the actual situation is understood, there are found to be very definite reasons for the change back to steam apparatus. We have heard for instance, that in the case of the large cargo vessel *Minnesota*, consideration is being given to the removal of the electric winches and providing same with steam. While we are not thoroughly informed as to all the difficulties encountered with these electric winches, which were installed quite a number of years ago, we are led to believe that if electric winches of the latest type and design were provided, that most of the criticisms would be taken care of. We trust that the manufacturers of the electrical equipments for the winches as now installed, are making a careful study of this particular situation and possibly can give us additional comments regarding the matter this evening

During the war the Petroleum Transport Co. constructed four oil barges which were provided with propelling machinery consisting of oil-fired boilers, steam turbines, operating two screws driven by a-c. motors, these motors being controlled from a central station by one master controller with straight line lever motion similar to steam valve mechanism. We understand that the Petroleum Transport Co. now contemplates the removal of this propelling apparatus and the installation of reciprocating steam engines. A very careful check of this situation has shown that the difficulty has been almost entirely one of operating conditions, that the vessels were designed for low speed of about 8½ knots and to make short cruises from port to port along the Gulf Coast; therefore being supplied with a very limited fuel and water capacity. It was later decided however, to put these boats on relatively long trips, from Tampico to Miami for example, for which they had neither the fuel nor fresh water capacity. Salt water has been apparently, the primary cause of all the troubles that these ships have experienced. With salt water in the boilers they primed considerably, resulting in deposit of salt and grit within the steam turbine, producing particularly serious corrosion of packings and shafts, and resulting in some cases, in a complete breakdown of the turbines. We are informed furthermore, that the engine room crews on these ships had not, on the whole, measured up to a high standard and in many cases carelessly wasted their fresh water supply. We understand that the new equipments are to comprise considerably larger boilers and more powerful engines with a desire to increase the speed of the boats. We are not informed as to how the question of fuel and water capacity is to be met, we are pleased however to report that although these equipments are to be removed,

no criticism whatever was found with the electrical apparatus; in fact its operation was reported to be highly satisfactory.

Conclusions

In conclusion, we feel that while the growth and adoption of electricity in this field was very slow for many years, that within the last three or four years in particular, definite and very rapid progress has been made. The popularity of the electric gear with those who have been concerned in its operation, would seem to have been well established where it has been given a fair and impartial trial.

The more rapid adoption of electric drive is now receiving decided impetus from the introduction of the fuel oil engine, and we now look for its general use at a very early date, as soon as many of the present equipments now being installed have been tried and the operators become familiar with the apparatus, and with the general thought that electricity instead of steam is operating their equipments for them.

We trust too, that everyone may be of an open mind on this subject, giving full opportunity for correction of first errors in later designs, as we feel it is still without question in the development stage, and where unfavorable reports are heard to assist in analyzing and reporting the true conditions which have led to failures and criticisms.

It is with a sense of gratification, therefore, that we feel our predictions of a number of years ago are being rapidly fulfilled.

Reestablishing Service in a D-C. Edison System after an Interruption

BY RAYMOND BAILEY
The Philadelphia Electric Co.

MOST of the large central station companies have certain areas to which 125–250-volt d-c. energy is supplied. In the days gone by, this direct current was generated in a number of stations having d-c. engine-driven generators. These generating stations were tied in by means of feeders with the "mains" which were laid in the streets and connected together to form an extensive network; the entire combination being known universally as an Edison system.

As the a-c. systems were developed and put into operation, the Edison networks were supplied with energy from them through motor-generator sets and later by means of synchronous converters.

Storage batteries were installed throughout the d-c. areas to carry the load of any station for a short time in case of trouble with generating equipment. It is not practicable in most cases to install enough battery capacity to carry the load for but a comparatively short length of time. The rapid growth of a-c. systems and in some instances that of the Edison systems has led to interruptions of pronounced magnitude and duration.

Experience indicates that there are, at times, interruptions of such length as will completely discharge the stand-by batteries, thus making it necessary to bring the system voltage up from zero to normal with d-c. machines. When d-c. generators are used for this work no trouble is experienced as the machine voltage can be reduced enough to permit their being connected to the network without taking an excessive load. That a considerable reduction in generator voltage is needed to make it possible to put the machine on the "line" will be evident when it is remembered that the network of d-c. mains with connected apparatus forms a very low resistance path for the current.

The extensive use of synchronous booster converters for Edison systems has complicated the problem as it is impossible to reduce the voltage of these machines much below 90 per cent of normal.

It is evident that in addition to taking the usual precautions to insure continuity of service, it is necessary where synchronous converters are used to supply the d-c. network, to provide means for readily reenergizing it should a complete interruption occur.

It may be possible to reestablish service by any one of the methods:

a. Reduction of a-c. system voltage.

b Use of a number of motor-generator sets.

c. Simultaneous closing of all machine circuit breakers.

d. Sectionalizing the network.

e. Use of load-limiting resistors in converter circuits.

f. Operation of converters on reduced voltage taps.

There are some a-c. systems which are so arranged and whose operating conditions are such that it is possible to isolate that part which supplies the Edison network and then reduce the voltage for the purpose of reestablishing service. The a-c. voltage is varied to give the desired d-c. voltage during the reenergizing period. This would appear to be a satisfactory method for reestablishing service where it is possible to carry it out.

If motor-generator sets are provided for restoring service, a fairly high percentage of the total machine capacity would consist of these sets. The disadvantages of this arrangement are in the larger space required by the

motor-generators and their lower efficiencies, as compared with the converter.

Closing the d-c. breakers of all of the converters on the system simultaneously in order to get the converters back on the line, has the advantage that it requires little additional equipment, but if Edison load is large compared to the generating capacity, it might be rather difficult to carry out successfully. This arrangement requires considerable control wiring between stations.

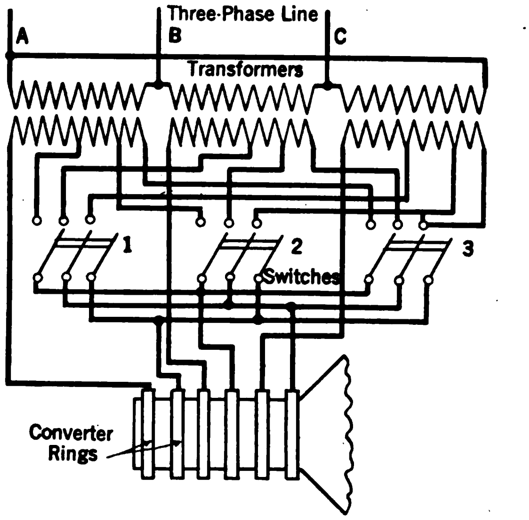

Fig. 1—Diagram of Connections Between Converter Transformers, Starting Switches and Converter Rings for Secondary Starting

Switches Nos. 1, 2 and 3 are interlocked so that only one switch can be closed at a time.

Sectionalizing the network in order to facilitate restoring service is very expensive and in many cases cannot be carried out for practical reasons.

It is not a good plan to use load-limiting rheostats except in certain special cases, because they are expensive and require considerable space which is very costly and often not available in the metropolitan districts.

It is likely that the method of restoring service which involves the operation of the converters on reduced voltage taps may prove satisfactory in certain systems. When secondary starting is used, the connections between transformers and converters for reduced voltage, starting and running, are as shown in Fig. 1. Voltages of 50 per cent, 75 per cent and 100 per cent may be obtained by closing respectively switches Nos. 1, 2 and 3. Fig. 2 shows the connections for high-tension starting. In this case voltages of 58 per cent, 72 per cent and 100 per cent are obtained by closing switches Nos. 1, 2 and 3 respectively.

Which one of the reduced voltage taps is used for starting depends upon the design of the converter. Manufacturers of synchronous booster converters state that these machines have been operated under load at reduced voltage and no trouble need be expected in the way of unstable operation, etc.

A comparison of the two schemes of connections will show that when rated direct current is carried on the converter, none of the transformer windings is overloaded provided the reduced voltage taps are on the low-voltage side of the transformer (Fig. 1), but the high-voltage windings are overloaded if the reduced voltage taps are on the high-voltage side (Fig. 2). If 75 per cent of running voltage is used to start the converter, 80 per cent of each of the high-voltage windings should be connected in the circuit which will give approximately the desired voltage. The exact per cent voltage obtained is equal to

$$\frac{100}{\sqrt{3} \times 0.8} = 72.5 \text{ per cent.}$$

This change in ratio of transformation will produce an overload current of 25 per cent in the high-voltage winding when the converter is carrying rated direct current. It is likely that most converter transformers, even though rated at maximum, will carry this overload current for at least one hour, as the core losses are much reduced due to the fact that only 72.5 per cent of rated voltage is applied. When the entire high-voltage windings are used in the *Y* connection to obtain a very low d-c. voltage, full-load current on the converter produces no overload on the transformers

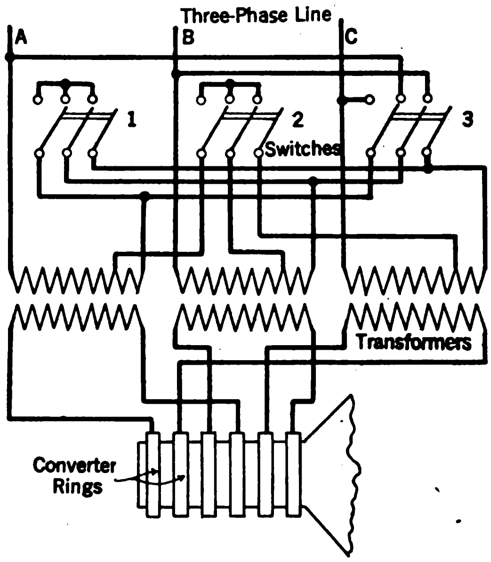

Fig. 2—Diagram of Connections Between Converter Transformers, Switches and Converter Rings for Primary Starting

Switches Nos. 1, 2 and 3 are interlocked so that only one switch can be closed at a time.

and the core losses are much reduced, as only 58 per cent of rated volts is applied.

In order to follow the proper procedure in reenergizing the network it is necessary to have the equipment arranged so that the maximum d-c. voltage of the converter operating on a certain transformer tap is approximately equal to the minimum voltage of the converter when running on the next higher tap.

It is probable that where converters are started

on 75 per cent of running volts, an additional reduced voltage tap will not be necessary. If 50 per cent of normal voltage is used for starting, a tap giving approximately 75 per cent volts will be required in order to obtain the necessary range of d-c. voltage. Table I gives voltage combinations for both primary and secondary starting and shows that with a 30-volt booster, the maximum voltage on certain taps does not equal the minimum voltage on the next higher tap. It is to be expected that under the conditions met in practise, it would be possible to make these voltages practically meet.

TABLE I

Tabulation of d-c. voltages obtained from the converters when operating on different transformer connections.

Secondary starting					Primary starting				
		D-c. volts					D-c. volts		
Switch closed	Tap	Min.	Neut.	Max.	Switch closed	Tap	Min.	Neut.	Max.
No. 1	50%	98	128	158	No. 1	58%	117	147	177
No. 2	75%	161	191	221	No. 2	72%	155	185	215
No. 3	Run	225	255	285	No. 3	Run	225	255	285

When the system balance is maintained by neutral connections on the converter transformers, high-tension starting is best, as the neutral can be closed during the entire reenergizing process, thus maintaining the desired balance. If secondary starting is used, the neutral connection can not be closed until the converter is operating on the running connection, thus making it necessary to maintain the balance in some other way.

In order to illustrate this method of reenergizing the network, assume a 200,000-ampere d-c. load (270 volts at bus) which before an interruption was carried by five of six 10,000-ampere converters in each of four stations. No reduced voltage tap in addition to the 75 per cent starting tap is provided. The load dispatcher would supervise the entire operation which could be carried out somewhat as follows:

The first step would be to start five machines in each station, four of which would be left running on the 75 per cent starting tap and the fifth on the running tap, all at maximum buck; the d-c. voltage of the converters on the starting taps being 161 volts and those on the running connection 225 volts. The breakers of the machines operating in the different stations on the starting tap would then be closed as nearly at the same time as possible, picking up about 6000 amperes per machine. The d-c. voltages of these machines would then be increased to maximum boost (approximately 221 volts) which would increase the amperes per machine to approximately 8200.

These figures on the load picked up by the machines at certain voltages are based on the assumption that the connected load does not change during the reenergizing period. Experience indicates that this assumption is the proper one to make as it introduces a factor of safety.

The one converter in each station operating at maximum buck on running voltage would then be connected to the d-c. system and fully loaded. This would relieve one converter in each station operating on the starting voltage, which could then be disconnected, changed over to running voltage, and loaded; which would in turn relieve another machine, which could be changed over to running voltage. This process is repeated until all machines are changed over to running voltage and the system voltage brought up to normal.

It is of course necessary to have arrangements made so that the booster fields of the converters can be supplied from some separate source of energy, such as the battery or the one converter which is operating on the running connection. Sufficient voltage for the booster fields could not be obtained when the converters are operating on the starting tap if the fields are supplied from the terminals of the converter.

If a reduced voltage tap in addition to the starting tap is provided, one more step is introduced into the operation of picking up the load, but on the other hand, less load is picked up when the machine breakers are first closed, which is advantageous.

It is advisable to energize the shunt fields of the converters from some external source during the starting period in order to secure correct polarity which will save considerable time in reestablishing service.

It can readily be seen that making provision in new installations for this method of picking up the load requires very little expenditure of money or space in the station, the addition of a small amount of switching equipment, transformer taps and connections being all that would be required in most cases. As a matter of fact the greatest difficulty lies in adapting the present installed equipment for operation with the new. Differences in starting voltages of the converters installed in the same station complicate the problem to a certain extent.

If for example, a substation has converters all arranged for secondary starting but some of them have 50 per cent starting taps and the remainder taps for 75 per cent, it might be possible to obtain the desired results as follows: Equip the high-voltage side of the converter transformers with oil circuit breakers for connecting the windings Y (normal connection delta), with 80 per cent of the turns of each phase in the circuit. After the machines have been started they would be closed in on the network with the 50 per cent machine operating with 50 per cent secondary winding and full primary winding delta-connected, and the 75 per cent machine with 75 per cent secondary winding and 80 per cent primary winding Y-connected. The next higher voltage would be obtained on the 50 per cent machine with full secondary and 80 per cent pri-

mary winding Y-connected, and on the 75 per cent machine with 75 per cent secondary winding and full primary winding delta-connected. The last or running voltages would of course be obtained in the usual way.

Where three-wire converters with a high unbalance capacity are installed, it may be possible to obtain the desired reduced voltage by having arrangements made so that either the positive or negative circuit breaker of the converter may be left open and the converter neutral connected to the bus on which the breaker is left open. This will give voltages about one-half as large as given in Table I for primary starting.

If the stations are operated with several busses at different voltages, it is of course necessary to take this into account when starting up the station. It might be found advisable to have the arrangements made for closing the d-c. circuit breakers on several of the converters at the same time by means of special control connections, so that the first machines which are connected to the system may be connected simultaneously, thus avoiding the possibility of having one or two trip off on overload.

The exact procedure to be followed in adapting the substations in any particular system to this method of reestablishing the Edison service can only be arrived at after making a thorough analysis of the problem.

While it is thought that the method of reenergizing outlined in detail will be found to be satisfactory, it is not the intention to give the impression that it is in general better than the other methods mentioned, as it is thoroughly realized that under certain conditions the method discussed would not be applicable at all. Which one of the methods of reestablishing service is made use of should be determined by making a comprehensive study of the situation.

Tooth Frequency Losses in Rotating Machines

BY THOMAS SPOONER

Westinghouse Electric & Mfg. Co.

Data are presented showing the hysteresis and eddy current losses due to minor displaced hysteresis loops superimposed on major loops of various amplitudes.

In all cases the amplitude of the minor loops is made proportional to the displacement which approximates the conditions which occur in machines. These data are applied to the case of the induction motor having a sine wave field distribution and a sample case worked out showing that the hysteresis losses in the teeth due to the tooth pulsations may be of the same order of magnitude as the losses due to the fundamental frequency. The eddy current losses in thin sheets due to the high-frequency pulsations are in general negligible but may be quite appreciable in the pole faces where the sheets are thicker. There are of course other losses due to tooth pulsations such as eddy current and circulating losses in the copper, etc., but these are beyond the scope of the present investigation.

Introduction

The calculation of core losses in rotating machines is based very largely on empirical data derived from tests of complete machines. That this procedure is followed is due to two chief causes.

1. The large magnitude and uncertainty of the illegitimate losses due to imperfections in manufacture such as bending strains in the sheet, burrs, filing of slots, etc.

2. Lack of sufficient fundamental data and design formulas.

The illegitimate losses are so large and variable at times that the designer feels that any refinement in calculations is a waste of time. This feeling on the part of the designer is largely responsible for the lack of design data since the designer has not demanded it.

When small changes only are made from standard designs the empirical data are fairly satisfactory, but when radically new designs are worked out, it frequently happens that the calculated losses are far from the true values. When a machine fails to meet the calculated losses, the designer should know whether the fault is due to his design or to poor shop practise. Of the various factors at present not subject to calculation which go to make up iron losses in rotating machines, those due to high-frequency tooth pulsations seemed to be the most important. In some cases it seems probable that these tooth pulsations may be responsible for more than 50 per cent of the total iron losses.

A few years ago a paper[1] was presented before the A. I. E. E. giving some data on displaced hysteresis loops. These data were rather meager and not very directly applicable to rotating machines since the authors considered only the displacement factor or the increase in hysteresis loss of a displaced minor loop occurring at the tip of a major loop over that of a symmetrical loop of the same amplitude. Referring to Fig. 1, the displacement factor is the ratio of the area of loop No. 1 to that of a small symmetrical loop at the center having the same B amplitude.

Recently the author has undertaken a further investigation along the same line in an effort to obtain results which are more nearly applicable to the conditions which exist in rotating machines.

Experimental Procedure

Test Samples. The experimental data were obtained on ring punchings from three kinds of material. The samples were 4 7/16 in. (11.27 cm.) outside diameter and 3 7/16 in. (8.73 cm.) inside diameter. These samples were mill annealed but not reannealed after punching. They weighed about one pound apiece and had the following characteristics:

Sample	Gage Inches	Silicon Content
A	0.028	2.25%
B	0.012	1.0 %
C	0.017	1.0 %

These materials are all standard electrical sheet. The silicon contents are only approximate.

Test Methods. These samples were wound with suitable primary and secondary windings and tested

TABLE I

Loop	B max = 10,000 Lower tip	Upper tip	B max = 15,000 Lower tip	Upper tip	B max = 17,000 Lower tip	Upper tip
1	8000	10000	12000	15000	13600	17000
2	4800	6000	8000	10000	9600	12000
3	2400	3000	4000	5000	4800	6000
4	−3000	−2400	−5000	−4000	−6000	−4800
5	−6000	−4800	−10000	−5000	−12000	−9600

ballistically, using a modification of a ring testing apparatus[2] previously described. The main hysteresis loops were measured by determining each point in-

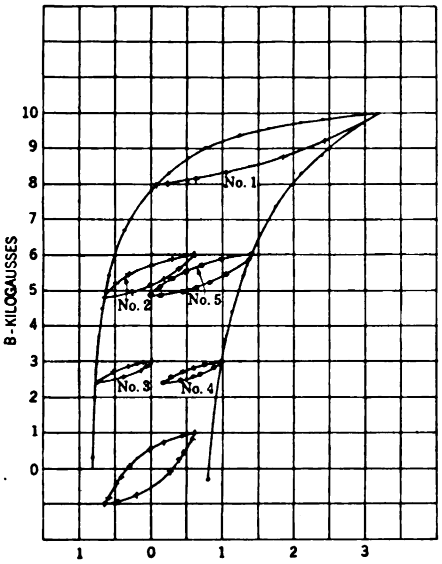

Fig. 1—Sample *C*

B_{max} equals 10 kilogausses. Amplitude of displaced loops equals 20 per cent of displacement.

dependently with reference to the tip value. The displaced loops were, for convenience, measured by means of the step by step method. The samples were placed in oil to avoid heating. Two primary and two secondary coils were used one set of a few turns and the other of many, thus making it possible to obtain high sensitivity for both low and high main loops. For testing high induction major loops, a sensitive ammeter was automatically switched into circuit when reading low values.

The procedure for determining a displaced minor loop was as follows:

The sample was brought into a cyclic condition for the major loop by reversing the magnetizing current

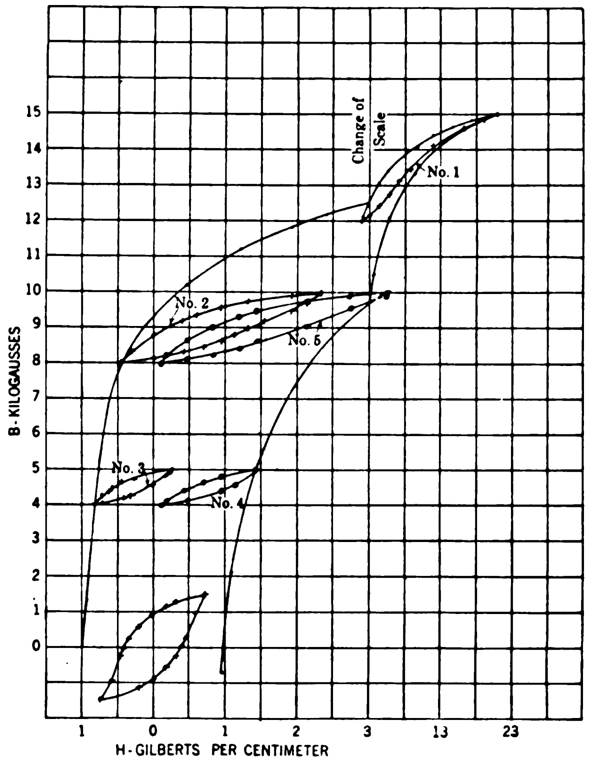

Fig. 2—Sample *C*

B_{max} equals 15 kilogausses. Amplitude of displaced loops equals 20 per cent of displacement.

a number of times. Then starting from the tip of the major loop, the induction was reduced to the lower tip of the minor loop in one step. From this point, step by step, we ascended to the upper tip of the displaced loop and then descended to the induction of the lower tip.

In all cases the amplitude of each displaced loop was 20 per cent of the displacement of the tip farthest from the zero line of induction. For each sample three maximum inductions for major loops were taken, namely, B = 10, 15 and 17 kilogausses. Table I gives the upper and lower tip values for all loops.

Test Results

A typical set of hysteresis loops for sample *C* are given by Figs. 1, 2 and 3 for maximum inductions of 10, 15 and 17 kilogausses respectively. The inductions were calculated from the net section as determined by the weight of the samples and an assumed specific gravity of 7.7. The losses for the major loops expressed in ergs per cu. cm. per cycle are given in Table II.

2. "Rapid Testing of Magnetic Materials," T. Spooner, *Electrical World*, Vol. 74, July 5, 1919.

The losses for the displaced loops are given by Table III.

These losses expressed in per cent of the major loop losses are given by Figs. 4, 5 and 6.

It will be noted that with the different major loops there happened to be associated a number of minor loops having the same amplitude and displacement. The losses for these loops have been collected in Table IV for convenient comparison.

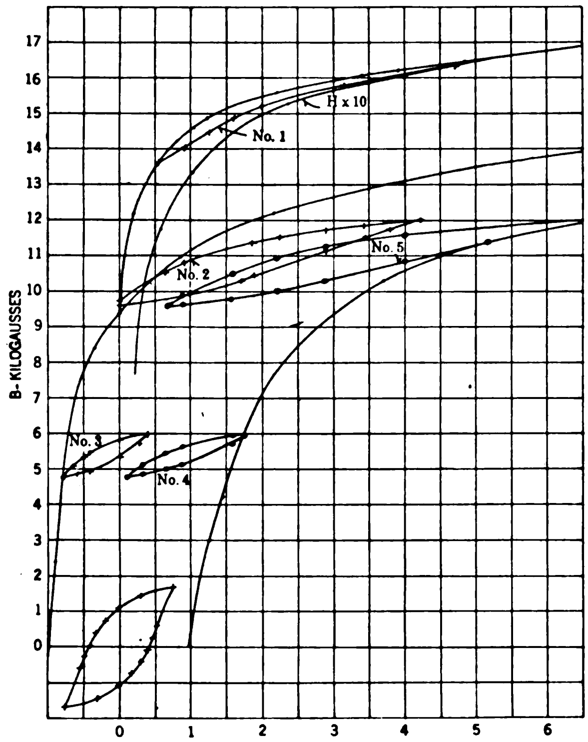

FIG. 3—SAMPLE *C*

B_{max} equals 17 kilogausses. Amplitude of displaced loops equals 20 per cent of displacement.

For comparison with previous work the displacement factors have been calculated for the No. 1 loops. Results are given in Table V.

TABLE II

B max	Sample A	Sample B	Sample C
10000	3110	2960	2780
15000	6000	7700	6252
17000	7930	10400	9010

Fig. 7 shows the effect of repeated reversals of magnetizing force on the hysteresis loss between the same maximum and minimum values of *H*. This particular curve is for a No. 4 displaced loop superimposed on a major loop of $B = 17$ kilogausses for the *B* ring and shows the difference between the first and fourth cycles for the same *H* amplitude.

CALCULATED RESULTS

Hysteresis Loss. In order to apply these results to specific conditions such as the loss in the teeth of an induction motor, calculations were made from the data of the *C* sample, assuming a sine-wave field form. On this assumption, the reference tip of each minor loop will be proportional to the cosine of the angle of rotation in electrical degrees, assuming that B_{max} occurs at an angle of 0 deg. Suppose now we assume 18 teeth per pole. This will correspond to a minor loop at each 10 electrical degrees. Now, if we multiply the cosine of the angle by B_{max}, this will give us the reference tip for each displaced loop corresponding to the abscissa of Fig. 6. Next we take the corresponding percentage losses from this curve for each 10 deg. over a range of 180 deg., add the percentages, multiply by two and we have the percentage hysteresis losses due to the displaced loops for a complete cycle. If this be done for various numbers of teeth it will be found that the losses are directly proportional to the number of teeth. We have then:

Table III

Loop	Ring No. A	Ring No. B	Ring No. C
Losses (Ergs) *B* max = 10			
1	147	148	162

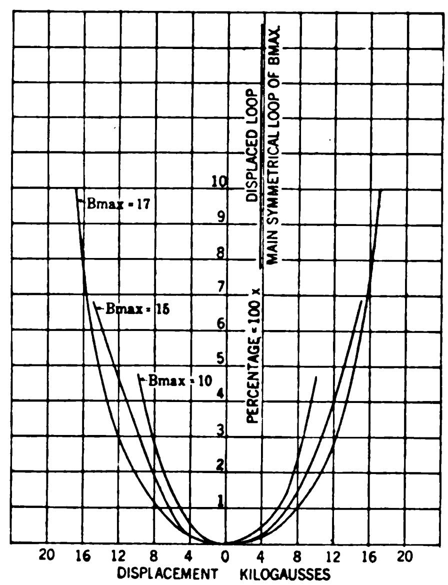

FIG. 4

$$P = K\,T \tag{1}$$

where P = the loss of the minor loops in per cent of the loss of the major loop,
K = a constant
T = teeth per pair of poles.

If the percentage loss as calculated above be divided by the number of teeth per pair of poles the results will be K for the given B_m and for an assumed pulsating induction of 20 per cent. In order to obtain K for other

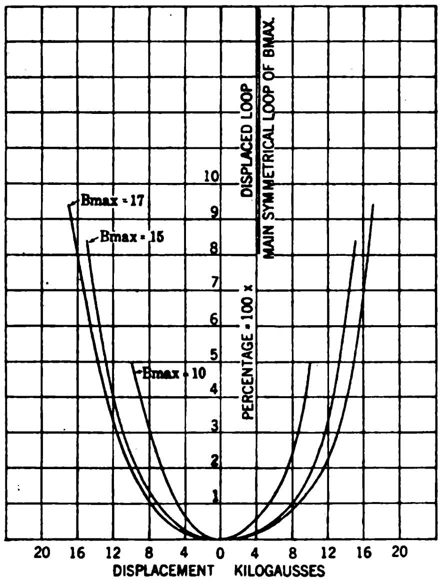

FIG. 5

pulsating amplitudes we assume that the hysteresis loss for the displaced loops is proportional to 1.6 power of the amplitude of the displaced loop. That this assumption is not far from the truth is shown by previous investigation[3] in which the exponent varied from about 1.6 to 1.5 for the larger displacements. Table VI gives these constants.

$P = K T$

P = percentage loss
K = constant
T = teeth per pair of poles

K 10/30 = K for B_m = 10 and ampl. of 30 per cent.

These results are plotted in Fig. 8. The total hysteresis loss due to the displaced loops may be calculated from the following formula:

$$W_{hd} = C K T f \qquad (2)$$

where W_{hd} = watts per kilogram for a given B_m.
C hysteresis loss in watts per kilogram per cycle for a given B_m, due to the major hysteresis loops.
K = a constant
T = teeth per pair of poles.
f = fundamental cycles per second.

C may be determined by the ordinary Epstein test for the particular material considered. The eddy current losses must of course be deducted from the Epstein test value and the result divided by the frequency. Or C may be calculated directly from the area of hysteresis loop as determined ballistically. In case of the induction motor, T must be reduced in proportion to the slip, namely,

$$T = T_1 \times \frac{\text{Rotor Speed}}{\text{Syn. Speed}}$$

where T_1 is the actual number of teeth.

This applies both to the rotor and stator. If the number of teeth in the rotor and stator are different the pulsating losses in the rotor teeth are based on the number of teeth in the stator, and the losses in the stator on the number of teeth in the rotor.

The same formula may be used for calculating the losses with the inductions expressed in lines per square inch, and the losses in watts per pound or per cubic inch. In this case the three values of B_m for the curve of Fig. 8 expressed in lines per square inch will be 64.5, 86.8 and 98.3 corresponding to 10, 15 and 17 kilogausses respectively. The only other change needed is to express C in term of watts per pound or watts per cubic inch as desired.

Eddy Losses. A formula for the corresponding eddy current losses in the iron may be calculated as follows;

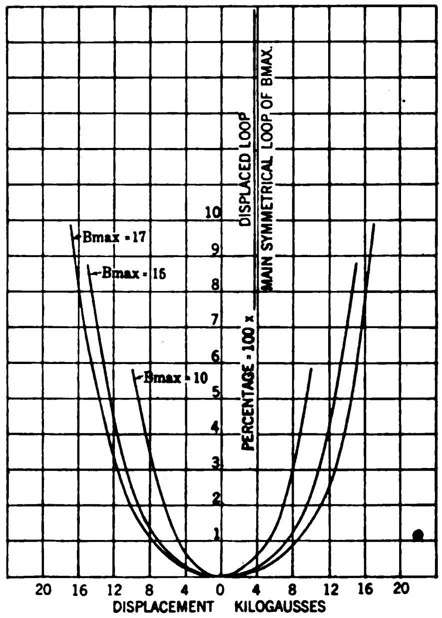

FIG. 6—SAMPLE C—1 PER CENT SILICON—0.0172-IN. GAGE
Displacement is based on tip farthest from O B. Amplitude of displaced loop is 20 per cent of displacement.

assuming as before a sine-wave field form. Let us assume an eddy current loss of 1.0 watt per kilogram at B_m = 10 kilogausses and 60 cycles. This is a fair value for 17-mil 1 per cent silicon steel. Assuming that the eddy loss is proportional to the square of the frequency and the square of the induction we get,

$$W_e = 2.78 \times 10^{-6} \times B^2 \times f^2 \qquad (3)$$

where W_e is in watts per kilogram
B is in kilogausses
f is in cycles per second

Let us assume 36 teeth per pair of poles (one tooth every 10 electrical degrees) a fundamental frequency

3. Ibid.

of 60 cycles, a B_m of 10 kilogausses and an amplitude of 20 per cent for the displaced loop. The harmonic frequency would then be 60 × 36 or 2160 cycles per second and the amplitude of the maximum displaced loop would then be 2 kilogausses corresponding to a B of one kilogauss. Applying these data to formula (3) and dividing by the harmonic frequency, we get

TABLE IV
Comparison of displaced loops having same amplitude.

the eddy loss for the maximum loop at 0 deg. This procedure is repeated for every 10 deg. the induction being numerically equal to the cosine of the angle. The eddy losses are then summed up for the complete cycle. The result for the eddy losses due to the displaced loops for the particular conditions specified in watts per kilogram is 1.08. Assuming that the

TABLE V
Displacement factors for rings A, B and C for 20 per cent loops.

Ring	$B = 10$	$B = 15$	$B = 17$

15	3	13.5
17	3.4	15.3

*B is the upper tip of the displaced loop.

eddy losses vary as the square law we may write the formula directly.

$W_{ed} = K\,(T \times t \times f \times P \times B_m)^2$ (4)

W_{ed} is expressed in watts per kilogram
T = teeth per pair of poles (with suitable corrections for slip as explained above.
t = thickness of laminations in inches
f = fundamental frequency in cycles per second
P = per cent amplitude of displaced loop
B_m = maximum induction in kilogausses per net section

By supplying 1.08 as calculated above in (4)
$K = 1.96 \times 10^{-9}$ which is an average constant for 17-mil 1 per cent silicon steel.

Of course, if the losses are to be expressed in units such as watts per cubic inch or the induction, thickness, etc., in other units the constant may be readily con-

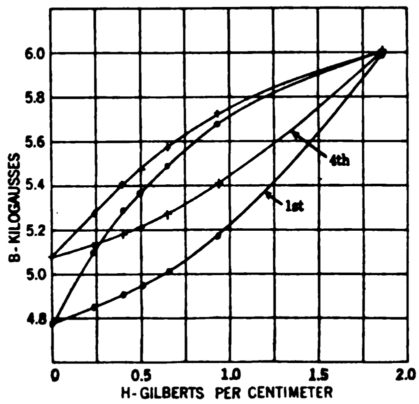

FIG. 7—SAMPLE B

Showing effect of repeated reversals of magnetizing force between the same H limits.
W_h equals 52.3 (1st) ergs per cu. cm. per cycle.
W_h equals 32.3 (4th) ergs per cu. cm. per cycle.

$$32.3\left(\frac{1.2}{0.92}\right)^{1.6} \text{ equals } 49.5 \text{ (cf. 52.3)}$$

verted to take care of these units. It must of course be changed for other materials, and will be approximately inversely proportional to the resistivity of the material. The assumed losses were for sheet having a

TABLE VI

$B_m = 10$	$B_m = 15$	$B_m = 17$
K 10/30 = 4.96	K 15/30 = 7.04	K 17/30 = 7.56
K 10/25 = 3.69	K 15/25 = 5.25	K 17/25 = 5.63
K 10/20 = 2.59	K 15/20 = 3.68	K 17/20 = 3.95
K 10/15 = 1.63	K 15/15 = 2.33	K 17/15 = 2.49

K 10/5 = 0.28	K 15/5 = 0.40	K 17/5 = 0.43

resistivity of about 23 microhms per centimeter cube. The resistivity for other silicon alloys may be calculated by the following formula:

$$R = a + k\,S \qquad (5)$$

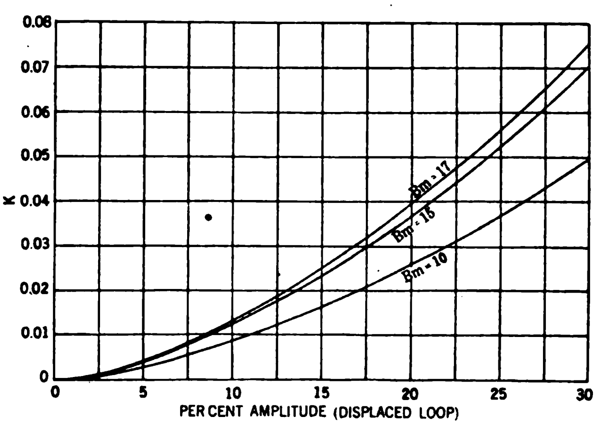

FIG. 8—FACTOR K FOR FORMULA (2) CALCULATED FROM DATA OF C SAMPLE

where R = The resistance in microhms per cm.[3]
a = 12
k = 11
S = silicon content in per cent.

As an example of the use of the above mentioned formulas and curves calculations will be made for the following conditions:

Material	= 1 per cent silicon steel
Thickness	= 17 mils
f	= 60 cycles
B_m	= 17 kilogausses
T	= 40 teeth per pair of poles
P	= 20 per cent (amplitude of displaced loops)

Let us also assume that the iron has a total loss due to the fundamental frequency of 12 watts per kilogram at $B_m = 17$ kilogausses which is a reasonable figure.

The eddy losses will then be from (3).

$W_e = 2.78 \times 10^{-6} \times 17^2 \times 60 = 2.90$ watts per kilogram.

The hysteresis losses is $12 - 2.9 = 9.1$ at 60 cycles and 0.152 per cycle.

The hysteresis loss due to the displaced loops is now from (2)

$W_{hd} = 0.152 \times 0.0398 \times 40 \times 60 = 14.5.$

The eddy losses due to the tooth pulsation are as follows from (4)

$W_{ed} = 1.96 \times 10^{-9} (40 \times 0.017 \times 60 \times 20 \times 17)^2 = 0.38.$ Therefore W (total) $= 12 + 14.5 + 0.38 = 26.9$ watts per kilogram.

Discussion of Results

The displaced hysteresis loops as determined by the method used do not altogether represent the conditions which exist in machines due primarily to the fact that these loops were obtained independently by starting each time from the tip of the major loop and going directly to the lower tip of the minor loops. In machines the minor loops follow one another with increasing or decreasing amplitude with a considerable number of minor loops superimposed on each major loop. It might be thought that this would have a demagnetizing effect tending to decrease the area of the loops. As a matter of fact there is such a tendency but it is small. Fig. 7 shows a fourth loop compared to a first loop, the former having a considerably smaller area than the latter. This is due chiefly to the fact that the fourth loop under the conditions of test has a smaller B amplitude although the H amplitude is the same. When the area of the fourth loop was multiplied by the 1.6 power of the difference in B amplitudes, the result nearly equals the areas of the No. 1 loop. In machines the conditions would correspond more nearly to definite B limits than definite H limits. In the A. I. E. E. paper referred to above, Fig. 24, page 2689, gives results on a first and tenth displaced loop taken between definite B limits of 7 and 9 kilogausses. The area of the first loop is 2.58 and of the tenth 2.32. We believe therefore that these different conditions will not introduce large errors. It is possible also that the minor loops may have an appreciable effect on the area of the major loops. If such an effect exists, it would be to decrease the losses due to the fundamental frequency.

It will be noted from Table IV and from Figs. 1 2 and 3 that the area of the displaced loops in general increases not only with the B displacement but with the H displacement also. In other words the No. 4 loop is usually larger than the No. 3 loop and the No. 5 loop larger than the No. 2. It will be noted that the percentage curves Figs. 4, 5 and 6 are nearly alike although the three samples are quite different in gage, chemical composition and losses. Therefore no large errors would probably be introduced by using these curves or the K curves of Fig. 8 for any class of electrical sheet having a silicon contents of not much over 2 per cent.
